BIRATIONAL PROPERTIES OF PENCILS OF DEL PEZZO SURFACES OF DEGREE 1 AND 2.

MIKHAIL GRINENKO

Abstract. In this paper we study the birational rigidity problem for smooth Mori fibrations on del Pezzo surfaces of degree 1 and 2. For degree 1 we obtain a complete description of rigid and non-rigid cases.

1. Notions and results.

Due to progress in the Minimal Model Program, the classification problem in the modern birational geometry for varieties of negative Kodaira dimension can be formulated as follows: given a class of birational equivalency, to describe all Mori fibrations and birational maps between them.

Recall that a normal variety $V$ with at most $\mathbb{Q}$-factorial terminal singularities is called a Mori fibration if there exists an extremal contraction $\varphi : V \to S$ of fibering type, i.e.

1) $\varphi$ is a morphism with connected fibers onto a normal variety $S$ and $\dim S < \dim V$;
2) $-K_V$ is $\varphi$-ample and the relative Picard number is equal to 1:

$$\rho(V/S) = \rho(V) - \rho(S) = 1.$$ 

Note that often comparing birational classes of varieties, we suffice to know Mori structures rather than Mori fibrations themselves (roughly speaking, Mori fibrations modulo birational maps over the base). From this viewpoint, the following class of varieties is rather important (and simple for describing):

**Definition 1.1.** A Mori fibration $V/S$ is said to be birationally rigid, if any birational map $\chi : V \dashrightarrow V'$ onto another Mori fibration $V'/S'$ is birational over the base ("square"), i.e., there exists a birational map

\[ \psi : S \to S' \text{ making the following diagram to be commutative:} \]

\[
\begin{array}{ccc}
V & \xrightarrow{\chi} & V' \\
\downarrow & & \downarrow \\
S & \xrightarrow{\psi} & S'
\end{array}
\]

Now let \( \rho : V \to S \) be a Mori fibration. Then any non-empty linear system \( D \) on \( V \) is a subsystem of \( |a(-K_V) + \rho^*(A)| \), where \( a = \mu(V, D) \geq 0 \) is the so-called quasi-effective threshold, and \( A \) is a divisor on \( S \). The behaviour of linear systems under birational maps between Mori fibrations is given by the following theorem ([1], theorem 4.2):

**Proposition 1.2.** Let \( \rho : V \to S \) and \( \rho' : V' \to S' \) be Mori fibrations, \( \chi : V \dashrightarrow V' \) a birational map, \( D' = |n'(-K_{V'}) + \rho'^*(A')| \) a very ample linear system on \( V' \), where \( A' \) is an ample divisor on \( S' \). Denote \( D = \chi_*^{-1}D' \subset |n(-K_V) + \rho^*(A)| \). Then:

(i) \( n \geq n' \) always, and if \( n = n' \) then \( \chi \) is square;
(ii) if a log pair \( K_V + \frac{1}{n}D \) is canonical and numerically effective, then \( \chi \) is an isomorphism inducing also an isomorphism between the bases.

The statement (i) of the proposition allows us to describe various Mori structures on \( V \), while (ii) can be used to get Mori models (i.e., various Mori fibrations birational to \( V \)).

There is another important number arising from the maximal singularities method (now playing the key role in the birational classification). This is so-called the adjunction threshold.

**Definition 1.3.** A non-negative number \( \alpha(V, D) \) is called the adjunction threshold of a pair \( (V, D) \), where \( D \) is a non-empty linear system without fixed components, \( V \) is projective and non-singular in codimension 1, if \( \alpha(V, D) \) is the smallest number such that for any positive integers \( m \) and \( n \) with \( \frac{m}{n} > \alpha(V, D) \) the linear system \( |nD + mK_V| \) is empty, where \( D \) is an element of \( D \).

The following statement clarifies the role of the adjunction threshold ([10], 2.1.):

**Proposition 1.4.** Let \( \chi : V \to V' \) be a birational map between terminal \( \mathbb{Q} \)-factorial varieties, \( D' \) a non-empty linear system on \( V' \) without fixed components, and \( D = \chi_*^{-1}D' \) its strict transform. If \( \alpha(V, D) > \alpha(V', D') \), then a pair \( K_V + \frac{1}{\alpha(V, D)}D \) is not canonical (in other words, \( D \) has a maximal singularity).
This condition “to be not canonical” is strong enough, and we can often either prove its impossibility, or decrease the adjunction threshold applying an ”untwisting“ birational automorphism or jumping to another Mori model (as in the Sarkisov program). A relation between both the thresholds is given by the following obvious lemma:

**Lemma 1.5.** Let $\mathcal{D} \subset |n(-K_V) + \rho^*(A)|$ be a non-empty linear system without fixed components on a Mori fibration $\rho : V \rightarrow S$. Always $n = \mu(V, \mathcal{D}) \geq \alpha(V, \mathcal{D})$, and if $A$ is effective, then the equality holds; if $C \circ \rho^*(A) < 0$ for a general curve $C$ covering the base, then $\mu(V, \mathcal{D}) > \alpha(V, \mathcal{D})$.

The key idea is that the relation between these thresholds determines whether a variety is rigid. For Mori fibrations that are pencils of del Pezzo surfaces, it looks as follows:

**Conjecture 1.6.** Let $V/\mathbb{P}^1$ be a pencil of del Pezzo surfaces of degree 1, 2 or 3 (we assume it to be a Mori fibration). $V/\mathbb{P}^1$ is birationally rigid if and only if $\alpha(V, \mathcal{D}) = \mu(V, \mathcal{D})$ for any linear system without fixed components (i.e., a linear system $|n(-K_V) - F|$ either is empty, or has a base divisor; here $F$ is the class of a fiber).

Let us note that ”nearly all” (smooth) pencils of del Pezzos of degree 1, 2 or 3 are sufficiently ”twisted” along the base, and in [9] their rigidity is proved. In this paper, we deal with all cases of degree 1 (theorem 2.6) and advance in degree 2 (theorem 3.1). In particular, conjecture 1.6 turns out to be true for smooth cases of degree 1.

The paper is based on using the maximal singularities method ([4], [6]) in its most perfect kind [10].

Everywhere in this paper the characteristic of the ground field is assumed to be 0.

The author would like to thank the Directors and the stuff of the Max-Planck Institute for Mathematics in Bonn for hospitality and excellent conditions during the work.

2. Smooth varieties with a pencil of del Pezzo surfaces of degree 1.

2.1. The essential construction. We follow to the idea given in [5].

Let $\rho : V \rightarrow \mathbb{P}^1$ be a smooth Mori fibration on del Pezzo surfaces of degree 1, $\text{Pic} V = \mathbb{Z}[-K_V] \oplus \mathbb{Z}[F]$, where $F$ is the class of a fiber. By the Grauert theorem, $\rho_*\mathcal{O}(-2K_V + mF)$ is a vector bundle of rank 4 on $\mathbb{P}^1$. We may choose $m$ such that

$$\mathcal{E} = \rho_*\mathcal{O}(-2K_V + mF) \simeq \mathcal{O} \oplus \mathcal{O}(n_1) \oplus \mathcal{O}(n_2) \oplus \mathcal{O}(n_3),$$

This condition “to be not canonical” is strong enough, and we can often either prove its impossibility, or decrease the adjunction threshold applying an ”untwisting“ birational automorphism or jumping to another Mori model (as in the Sarkisov program). A relation between both the thresholds is given by the following obvious lemma:

**Lemma 1.5.** Let $\mathcal{D} \subset |n(-K_V) + \rho^*(A)|$ be a non-empty linear system without fixed components on a Mori fibration $\rho : V \rightarrow S$. Always $n = \mu(V, \mathcal{D}) \geq \alpha(V, \mathcal{D})$, and if $A$ is effective, then the equality holds; if $C \circ \rho^*(A) < 0$ for a general curve $C$ covering the base, then $\mu(V, \mathcal{D}) > \alpha(V, \mathcal{D})$.

The key idea is that the relation between these thresholds determines whether a variety is rigid. For Mori fibrations that are pencils of del Pezzo surfaces, it looks as follows:

**Conjecture 1.6.** Let $V/\mathbb{P}^1$ be a pencil of del Pezzo surfaces of degree 1, 2 or 3 (we assume it to be a Mori fibration). $V/\mathbb{P}^1$ is birationally rigid if and only if $\alpha(V, \mathcal{D}) = \mu(V, \mathcal{D})$ for any linear system without fixed components (i.e., a linear system $|n(-K_V) - F|$ either is empty, or has a base divisor; here $F$ is the class of a fiber).

Let us note that ”nearly all” (smooth) pencils of del Pezzos of degree 1, 2 or 3 are sufficiently ”twisted” along the base, and in [9] their rigidity is proved. In this paper, we deal with all cases of degree 1 (theorem 2.6) and advance in degree 2 (theorem 3.1). In particular, conjecture 1.6 turns out to be true for smooth cases of degree 1.

The paper is based on using the maximal singularities method ([4], [6]) in its most perfect kind [10].

Everywhere in this paper the characteristic of the ground field is assumed to be 0.

The author would like to thank the Directors and the stuff of the Max-Planck Institute for Mathematics in Bonn for hospitality and excellent conditions during the work.

2. Smooth varieties with a pencil of del Pezzo surfaces of degree 1.

2.1. The essential construction. We follow to the idea given in [5].

Let $\rho : V \rightarrow \mathbb{P}^1$ be a smooth Mori fibration on del Pezzo surfaces of degree 1, $\text{Pic} V = \mathbb{Z}[-K_V] \oplus \mathbb{Z}[F]$, where $F$ is the class of a fiber. By the Grauert theorem, $\rho_*\mathcal{O}(-2K_V + mF)$ is a vector bundle of rank 4 on $\mathbb{P}^1$. We may choose $m$ such that

$$\mathcal{E} = \rho_*\mathcal{O}(-2K_V + mF) \simeq \mathcal{O} \oplus \mathcal{O}(n_1) \oplus \mathcal{O}(n_2) \oplus \mathcal{O}(n_3),$$
where $0 \leq n_1 \leq n_2 \leq n_3$. Suppose $b = n_1 + n_2 + n_3$.

Note that there exists a special section $s_B$:

$$s_B = Bas| - K_V + kF|$$

for $k \gg 0$. Obviously, any fiber $S \in |F|$ is smooth at the point $s_B \cap S$, which is also a unique base point of $| - K_S|$.

Let $\pi : X \to \mathbb{P}^1$ be a natural projection for $X = \text{Proj } \mathcal{E}$; $\varphi : V \to X$ a morphism defined by $| - 2K_V + mF|$. Then $\rho = \pi \circ \varphi$. It is easy to see that if $Q \subset X$ is the image of $\varphi$, then $\varphi : V \to Q$ is a degree 2 finite morphism branched along a smooth divisor $R_Q = R \cap Q$ that does not intersect $t_B = \varphi(s_B)$, where $R \subset X$ is a divisor.

$Q$ is restricted to any fiber $T$ of $X/\mathbb{P}^1$ as a non-degenerated quadratic cone with $T \cap t_B$ as its vertex, and $R|_T$ is a cubic surface. So if $M$ is the class of the tautological bundle on $X$ and $L$ is the class of a fiber, we have

$$Q = 2M + aL; \quad R = 3M + cL.$$

Let $t_0$ be a section corresponding to the surjection $\mathcal{E} \to \mathcal{O} \to 0$, $l$ the class of a line in $L \cong \mathbb{P}^3$; set $t_B \sim t_0 + \varepsilon l$, where $\varepsilon$ is obviously nonnegative.

Choose a very ample divisor $H \sim M + \beta l$, $\beta > 0$. So $D = H \cap Q$ is a conic bundle with $N = t_B \circ H$ degenerations. We may suppose that all fibers of $D$ are reduced and all its singular points are du Val $A_1$. It is easy to compute that $K^2_D = 8 - 2b - 2\beta - 3a$. Let us blow up all singular points of $D$ and then contract all (-1)-curves (there will be $2N$ of them) onto a ruled surface $D'$. We have

$$K^2_D + 2N = K^2_{D'} = 8,$$

hence

$$N = b + \beta + \frac{3}{2}a.$$

Note that $a$ must be even. Set $a = 2a'$. Then,

$$N = t \circ H = (t_0 + \varepsilon l) \circ (M + \beta l) = \beta + \varepsilon,$$

and we obtain $\varepsilon = b + 3a'$. Since $R|_Q \cap t_B = \emptyset$, we have $0 = (t_0 + \varepsilon l) \circ (3M + cL) = 3\varepsilon + c$. So, we have proved the following lemma:

**Lemma 2.1.** The following equalities hold:

$$Q = 2M - \frac{2}{3}(b - \varepsilon)L,$$

$$t_B = t_0 + \varepsilon l,$$

$$R = 3M - 3\varepsilon L.$$
In the sequel we will always assume \( b > 0 \). Really, if \( b = 0 \), then \( Q = 2M \) and \( \varepsilon = 0 \), whence \( V \cong \mathbb{P}^1 \times S \) for some smooth del Pezzo surface \( S \). So \( V \) is rational and even not a Mori fibration because of the Picard group rank.

**Lemma 2.2.** The only following two cases may occur:

1) \( \varepsilon = 0 \), \( 2n_2 = n_1 + n_3 \), \( n_1 \) and \( n_3 \) are even; so we have

\[
Q = 2M - 2n_2L, \quad t_B = t_0, \quad R = 3M;
\]

2) \( \varepsilon = n_1 > 0 \), \( n_3 = 2n_2 \), \( n_1 \) is even and \( n_2 \geq 3n_1 \); in this case

\[
Q = 2M - 2n_2L, \quad t_B = t_0 + n_1l, \quad R = 3M - 3n_1L.
\]

**Proof.** Suppose first \( \varepsilon > 0 \). Then \( \varepsilon \geq n_1 \) because of irreducibility of \( t_B \). Since \( R \) is irreducible and curves of the class \( t_0 + n_2l \) sweep any effective divisor of the class \( M - n_3L \), we have \( (t_0 + n_2l) \circ R = 3n_2 - 3\varepsilon \geq 0 \), i.e., \( \varepsilon \leq n_2 \).

Let \( n_1 = n_2 = n_3 \). Since \( t_B \circ (M - n_1L) = 0 \), the linear system \( |M - n_1L| \) is two-dimensional, and any of its elements is irreducible, there exists at least one-dimensional subsystem in \( t \) that contains \( t_B \). Let \( C \in |M - n_1L - t_B| \) be a general element, then

\[
Q \circ C = S + S' \sim 2M^2 - 2 \left( \frac{1}{3}(b - \varepsilon) + n_1 \right) ML,
\]

where \( S \) and \( S' \) are ruled surfaces covering the base. Note that there exists only a unique curve of the class \( t_0 \), and \( t_B \cap t_0 = \emptyset \). At least one of these surfaces, say, \( S \), contains both \( t_0 \) and \( t_B \). It is easy to see that \( S \) is of the class \( M^2 - 2n_1ML \), whence \( S' \sim M^2 - \frac{4}{3}n_1ML \). Since \( S \neq S' \), then \( t_0 \not\subset S' \), and denoting by \( B \) the intersection of two general elements of \( |M - n_1L| \), we can see that \( \dim(S' \cap B) = 0 \) (note that \( \text{Bas} |M - n_1L| = t_0 \)). We get a contradiction:

\[
0 \leq S' \circ P = (M^2 - \frac{4}{3}n_1ML) \circ (M^2 - 2n_1ML) = -\frac{n_1}{3} < 0.
\]

So if \( \varepsilon \geq n_1 \) then \( n_1 < n_3 \); moreover, \( n_1 > 0 \) because of irreducibility of \( R_Q \) (otherwise, if \( n_1 = 0 \), there should be at least 1-dimensional family of lines of the class \( t_0 \) sweeping a surface, and \( R_Q \) should contain it).

Let \( G \) be an irreducible ruled surface that is the complete intersection of general elements of \( |M - n_2L| \) and \( |M - n_3L| \). Let us show that \( t_B \subset G \). Indeed, \( G \) has the type \( \mathbf{F}_{n_1} \) with \( t_0 \) as its exceptional section. Assume the converse, i.e., \( t_B \not\subset G \). Then, for a general fiber \( S \in |L| \), the line \( G|_S \) does not lie on \( Q|_S \). So \( G \not\subset Q \), and we may suppose that...
\( G \circ Q = t_0 + C \), where \( C \) is a curve with no \( t_0 \) as a component. It is easy to compute that

\[
C \sim t_0 + 2 \left( b - n_2 - n_3 - \frac{b - \varepsilon}{3} \right) l,
\]

and

\[
2 \left( b - n_2 - n_3 - \frac{b - \varepsilon}{3} \right) \geq n_1,
\]

which, taking into account \( \varepsilon \leq n_2 \), gets a contradiction: \( n_1 > \frac{4}{3}n_1 \).

So \( t_B \subset G \), hence \( n_2 < n_3 \). In fact, the equality should led \( \dim |M - n_3L| \), thus \( \text{Bas} |M - n_3L| = t_0 \), and we could always find \( G \) such that \( t_B \not\subset G \).

By \( T \) we denote a unique effective element of \( |M - n_3L| \). We show that \( T\mid_Q = 2G \). Indeed, assuming the converse, i.e., \( T\mid_Q = G + G' \), \( G \neq G' \), and taking into account that \( t_B \subset G \cap G' \) and \( t_0 \subset G \), we see \( t_0 \not\subset G' \). Then

\[
G'\mid_G = t_0 + \#(t_0 \cap t_B = \varepsilon - n_1) \text{ fibers.}
\]

Choose a general \( S \in |M - n_1L| \). It is clear that \( S\mid_T \) is a ruled surface of the type \( F_{n_2} \) with the exceptional section \( t_0 \), and \( G \cap S\mid_T = t_0 \).

Let \( C = G' \cap S\mid_T \) be an irreducible curve. We have \( C \circ t_0 = \varepsilon - n_1 \), \( Q \circ T \circ S = t_0 + C \), whence

\[
C \sim t_0 + 2 \left( n_2 - \frac{b - \varepsilon}{3} \right) l.
\]

This yields \( C \circ t_0 = n_2 - \frac{2}{3}(b - \varepsilon) = \varepsilon - n_1 \), and we get a contradiction again:

\[
\varepsilon = n_1 + n_2 - 2n_3 < 0.
\]

So we have

\[
T \circ Q = 2M^2 - 2 \left( n_3 + \frac{b - \varepsilon}{3} \right) ML = 2G = 2(M^2 - (n_2 + n_3)ML),
\]

thus \( 2n_2 = n_1 + n_3 - \varepsilon \). If \( \varepsilon \) were greater than \( n_1 \), then \( R_Q \) should contain \( G \), because \( G \) is covered by curves of the class \( t_0 + n_1l \). This contradicts to irreducibility of \( R_Q \). So \( \varepsilon = n_1 \) and then \( 2n_2 = n_3 \). In order to show \( n_2 \geq 3n_1 \), we note that \( S_Q = S \cap Q \) is a conic bundle without degenerations, i.e., a ruled surface of the type \( F_{n_2} \). Then \( R \) cuts off an effective curve on \( S_Q \) that does not contain \( t_0 \), and \( t_0 \) itself. We get \( 3n_3 - 3n_1 \geq 5n_2 \), which yields \( n_2 \geq 3n_1 \).

It remains to show that \( n_1 \) is even. Let \( C \sim t_0 + n_1l \) be a general irreducible curve on \( G \), and \( C_V \) its inverse image on \( V \). Then \( C_V \) covers \( C \) with the ramification divisor of degree \( t_B \circ C = n_1 \). Clearly, this degree must be even. This completes the case \( \varepsilon > 0 \).
Now let $\varepsilon = 0$. We may assume $n_1 < n_3$. Take $T \in |M - n_3L|$. It is easy to observe that $T = \text{Proj} \ E_T$, where

$$E_T = \mathcal{O} \oplus \mathcal{O}(n_1) \oplus \mathcal{O}(n_2).$$

Since $T$ can be covered by curves of the class $t_0 + n_2l$ and $Q \sim 2M - \frac{2}{3}bL$ is irreducible, then $n_2 \geq \frac{b}{3}$, i.e., $2n_2 \geq n_1 + n_3$, and $n_2 > n_1$ since $n_3 > n_1$.

Further, let $C \sim t_0 + n_1l$ be irreducible. Since $b = n_1 + n_2 + n_3 > 3n_1$, then $C \circ Q = 2(n_1 - \frac{b}{3}) < 0$, and therefore $C \subset Q$. A ruled surface $G \sim (M - n_2L) \circ (M - n_3L) = M^2 - (n_2 + n_3)ML$ has the type $F_{n_3}$ and can be covered by curves of the same class as $C$, so $G \subset Q$. Therefore, $T|_Q = G + G'$ for some $G'$.

Let $M_T = M|_T$ be the tautological divisor on $T$, $L_T = L|_T$. Then $G$ has the class $M_T - n_2L_T$ in $T$, $Q|_T \sim 2M_T - \frac{3}{2}bL_T$, whence $G' \sim M_T - (\frac{3}{2}b - n_2)L_T$. Note that $\frac{3}{2}b - n_2 > n_1$ since $n_1 < n_2$.

But $T$ has only one divisor of the form $M_T - xL_T$ for $x > n_1$: this is $M_T - n_2L_T$. So $\frac{3}{2}b - n_2 = n_2$, hence $n_1 + n_3 = 2n_2$.

Now, let $C \subset Q$ be a general irreducible curve of the class $t_0 + n_1l$, $C_V$ its inverse image on $V$. Then $C_V$ is the double cover of $C$ branched along a divisor of degree $R \circ C = 3n_1$, whence $n_1$ and $n_3$ are even.

Lemma 2.2 is proved.

Such a construction of $V$ allows us to deal completely with intersections of cycles on $V$. Denote $G_V$, $F$, and $H$ the inverse images of $G \sim (M - n_2L) \circ (M - n_3L)$, $L_Q = L|_Q$, and $M_Q = M|_Q$ on $V$ respectively. Then, let $2s_0$ be the pull back of $t_0$, and $2f$ the pull back of a line in a fiber of $L_Q$.

**Lemma 2.3.** $\overline{\text{NE}}(V) = \text{NE}(V) = \mathbb{R}_+[s_0] \oplus \mathbb{R}_+[f]$, and:

1) if $\varepsilon = 0$, then $K_V = -G_V + (\frac{1}{2}n_1 - 2)F$, $H = 2G_V + n_3F$, $K_V^2 = s_0 + (4 - n_2)f$, $s_0 \circ f = f \circ G_V = 1$, $s_0 \circ G_V = -\frac{1}{2}n_3$, $f \circ F = 0$.

2) if $\varepsilon = n_1 > 0$, then $K_V = -G_V - (\frac{1}{2}n_1 + 2)F$, $H = 2(G_V + n_2F)$, $s = s_0 + \frac{1}{2}n_1f$, $K_V^2 = s_0 + (4 + \frac{3}{2}n_1 - n_2)f$, $s_0 \circ f = f \circ G_V = 1$, $s_0 \circ G_V = -\frac{1}{2}n_3 = -n_2$, $f \circ F = 0$.

**Proof.** It can be easily checked by the following way. First blow up $t_B$ on $Q$ with an exceptional divisor $S$; then take the double cover branched along a smooth divisor composed from the pre-image of $R_Q$ and $S$; after that, contract the pre-image of $S$ onto $s_B$.

**Lemma 2.4.** Let $\varepsilon = 0$ (i.e., $s_B = s_0$). If $|n(-K_V) - mF|$, $m > 0$, has no fixed components, then $n_3 = 2$. 
Proof. Let $D \in |n(-K_V) - mF|$. Since
$$D|_{\mathcal{G}_V} \sim n{s_0} - \left( m + n\left( \frac{n_1}{2} + n_3 - n_2 - 2 \right) \right) f$$
is an effective curve, we obtain
$$0 < \frac{m}{n} \leq 2 + n_2 - n_3 - \frac{n_1}{2} = 2 - \frac{n_3}{2}.$$It only remains to take into account that $n_3$ is positive and even. The lemma is proved.

Lemma 2.5. Let $\varepsilon = n_1 > 0$ (so $s_B \neq s_0$). If $|n(-K_V) + mF|$ has no fixed components, then $m > 0$.

Proof. Let $D \in |n(-K_V) + mF|$. Since
$$D|_{\mathcal{G}_V} \sim n{s_0} + [m + n(n_1 - n_2 + 2)] f$$is an effective curve, we have $2 + n_1 - n_2 + \frac{m}{n} \geq 0$. Using $n_2 \geq 3n_1$, we see that $2 + n_1 - n_2 \leq 2 - 2n_1 < -2$, whence $m > 0$. The lemma is proved.

2.2. Results about rigidity.

Theorem 2.6. Conjecture 1.6 is true for smooth Mori fibrations on del Pezzo surfaces of degree 1 (over $\mathbb{P}^1$).

In order to prove this theorem, we shall use the following proposition:

Proposition 2.7. Let $V/\mathbb{P}^1$ be a smooth Mori fibration on del Pezzo surfaces of degree 1, $V'/S'$ another Mori fibration, $\chi : V \dashrightarrow V'$ a birational map. Suppose that
$$\mathcal{D}' = |n'(-K_{V'}) + \text{pull back of an ample divisor from the base} |$$is a very ample linear system. Suppose aslo
$$\mathcal{D} = \chi_*^{-1}\mathcal{D}' \subset |n(-K_V) + mF|$$for some $m \geq 0$.

Then $n = n'$ (so $\chi$ is birational over the base), possibly except the case $\varepsilon = n_1 = 0, n_2 = 1, n_3 = 2$.

Proof of the proposition. By lemma 1.5, $\mu(V', \mathcal{D}') = n' = \alpha(V', \mathcal{D}')$ and $\mu(V, \mathcal{D}) = n = \alpha(V, \mathcal{D})$. If $n = n'$, the assertion follows from proposition 1.2. Suppose $n > n'$. Then a log pair $K_V + \frac{1}{n}\mathcal{D}$ is not canonical, i.e., the linear system $\mathcal{D}$ has a maximal singularity over some point. But using [9], we may say a little more.
Namely, let $D_1, D_2$ be general elements of $\mathcal{D}$. We observe that

$$D_1 \circ D_2 = \begin{cases} n^2s_0 + ((4 - n_2)n^2 + 2mn)f, & \text{if } \varepsilon = 0 \\ n^2s_0 + ((4 + \frac{3}{2}n_1 - n_2)n^2 + 2mn)f, & \text{if } \varepsilon = n_1 > 0 \end{cases}$$

Put down $D_1 \circ D_2 = Z^h + Z^v$, where $Z^h$ and $Z^v$ are horizontal and vertical cycles respectively. Then there exist a geometric discrete valuation $\nu$ centered at a point $B_0$ over some point $t \in \mathbb{P}^1$, and a positive number $e = \nu(D) - n\delta$, where $\delta$ is the canonical multiplicity with respect to $\nu$, such that for the component $Z^v_t \subset F_t$ of the cycle $Z^v$ in the fiber $F_t$ over the point $t$ we have

$$\deg Z^v_t < \begin{cases} (4 - n_2)n^2 + 2n_1\frac{f}{(F_t)}, & \text{if } \varepsilon = 0 \\ (4 + \frac{3}{2}n_1 - n_2)n^2 + 2n_1\frac{e}{(F_t)}, & \text{if } \varepsilon = n_1 > 0, \end{cases}$$

where $\deg Z^v_t \overset{\text{def}}{=} Z^v_t \circ (-K_V)$ (this is so-called the supermaximal singularity condition, in the notions of [9]). Besides, there exist positive numbers $\Sigma_0, \Sigma_0', \Sigma_0 \leq \Sigma_0, \Sigma_1$ such that multiplicities $m^h$ and $m^v$ of the cycles $Z^h$ and $Z^v$ at $B_0$ satisfy

$$(\Sigma_0 + \Sigma_1)(m^h\Sigma_0 + m^v\Sigma_0') > (2n\Sigma_0 + n\Sigma_1 + e)^2.$$ 

Note that $m^h \leq \deg Z^h \overset{\text{def}}{=} Z^h \circ F = n^2$ and $m^v \leq 2\deg Z^v_t$. So, in the case $\varepsilon = n_1 > 0$ we have

$$(\Sigma_0 + \Sigma_1)((9 + 3n_1 - 2n_2)n^2\Sigma_0 + 4ne) > (2n\Sigma_0 + n\Sigma_1 + e)^2,$$

hence

$$(2n_2 - 3n_1 - 5)\Sigma_0(\Sigma_0 + \Sigma_1) + (n\Sigma_1 - e)^2 < 0,$$

i.e., $2n_2 < 5 + 3n_1$. Taking into account the condition $n_2 \geq 3n_1$, we obtain $n_1 \leq 1$, which is impossible because $n_1$ must be even.

Now let $\varepsilon = 0$. Then

$$(\Sigma_0 + \Sigma_1)((8 - 2n_2)n^2\Sigma_0 + 4ne) > (2n\Sigma_0 + n\Sigma_1 + e)^2,$$

whence

$$(2n_2 - 5)\Sigma_0(\Sigma_0 + \Sigma_1) + (n\Sigma_1 - e)^2 < 0.$$ 

So $n_2 < \frac{5}{2}$, so the only three cases are possible:

- $n_1 = 0, n_2 = 2, n_3 = 4$;
- $n_1 = 2, n_2 = 2, n_3 = 2$;
- $n_1 = 0, n_2 = 1, n_3 = 2$.

We show that the first two cases can not occur. Suppose first that there are no sections of the class $s_0$ through the point $B_0$. Let $Z^h_1$ be
the sum of all horizontal cycles through $B_0$. So $Z_1^h \sim A s_0 + B f$ for some $B \geq A$. Since $n_2 = 2$ in the considering cases, we have
\[
\sum_{p \in P} \deg Z_v^v \leq 2n^2 + 2mn - B \leq 2n^2 + 2mn - A,
\]
which implies the following inequality for the supermaximal singularity:
\[
m^v \leq 2 \deg Z_v^v < 4n^2 + 4n \frac{e}{\nu(F_t)} - 2A.
\]
But we know that $m^h \leq A$, and then
\[
(\Sigma_0 + \Sigma_1) (A \Sigma_0 + (4n^2 - 2A) \Sigma_0 + 4ne) > (2n\Sigma_0 + n\Sigma_1 + e)^2,
\]
so we get a contradiction:
\[
A \Sigma_0 (\Sigma_0 + \Sigma_1) + (n\Sigma_1 - e)^2 < 0.
\]
It remains to prove that there are no maximal singularities over points that lie on sections of the class $s_0$.

Consider the case $n_1 = n_2 = n_3 = 2$. Note that $s_B \sim s_0$ is a unique section of such a class in this case. If $D$ has a maximal singularity over the point $B_0 \in s_B$, then for a general $D \in D$ it holds $\nu_1 = \text{mult}_{B_0} D > n$, and for a general curve $C \sim f$ in the fiber through $B_0$ we get $n = D \circ C \geq \nu_1 > n$, which is impossible.

Now let $n_1 = 0, n_2 = 2, n_3 = 4$. Proving of this case consists of two lemmas below and an observation that any curve of the class $s_0$ lies on the divisor $G_V$. Recall that the valuation $\nu$ can be realized as a chain of blow-ups centered in nonsingular centers $B_0, B_1, \ldots$; a general $D \in D$ has multiplicities $\nu_1, \nu_2, \ldots$ in these centers respectively.

**Lemma 2.8.** Let $D \subset |n(-K_V) + mF|, m \geq 0$, has a maximal singularity over a point $B_0 \in S$, where $S$ is a fiber of $V/\mathbb{P}^1$. By $l \in |-K_S|$ we denote the curve through $B_0$. Then

- a) $S$ is smooth at $B_0$;
- b) $B_0$ is a double point of $l$;
- c) $\nu$ defines an infinitely near singularity, and if $B_1 \cap S^1 \neq \emptyset$ (upper indices denote the strict transform on the corresponding floor of the chain of blow-ups realizing $\nu$), then $B_1 \cap l^1 \neq \emptyset$ and $\nu_1 + \nu_2 \leq 3n$.

**Proof.** If $S$ is singular at $B_0$, then a general curve $C \in |2(-K_S) - B_0|$ is also singular at this point, so we get a contradiction:
\[
2n = D \circ C \geq 2\nu_1 > \nu_1.
\]
Further, suppose $l$ is nonsingular at $B_0$. Set
\[
D|_S \sim kl + C,
\]
where $l \not\subset \text{Supp } C$. We have
\[ n < \nu_1 \leq \text{mult}_{B_0} D|_S = k + \text{mult}_{B_0} C. \]

But $\text{mult}_{B_0} C \leq C \circ l = (n(-K_S) - kl) \circ l = n - k$, and then
\[ n < \nu_1 \leq k + n - k = n. \]

So $l$ has a double point at $B_0$. Now we show that $\nu$ defines an infinitely near singularity. Assuming the converse, we get $\nu_1 > 2n$. Supposing $D|_S \sim kl + C$, we see that
\[ 2 \text{mult}_{B_0} C \leq C \circ l = n - k, \]
whence
\[ 2n < \nu_1 \leq 2k + \text{mult}_{B_0} C \leq \frac{3}{2}k + \frac{1}{2}n, \]
i.e., $k > n$, a contradiction.

Now let $B_1 \cap S^1 \neq \emptyset$, but $B_1 \cap l^1 = \emptyset$. Denote $E_1$ the exceptional divisor of the blow-up of $B_0$. Then
\[ D^1|_{S^1} = (D \circ S)^1 + mE_1|_{S^1}, \]
and for the decomposition $D|_S \sim kl + C$ we get
\[ \tilde{\nu}_1 + \tilde{\nu}_2 \leq 2k + \text{mult}_{B_0} C + \text{mult}_{\tilde{B}_1} C^1 + m, \]
where $\tilde{B}_1 = B_1 \cap S^1$, $\tilde{\nu}_1 = \text{mult}_{B_0} D|_S$, $\tilde{\nu}_2 = \text{mult}_{\tilde{B}_1}(D|_S)^1$. Then,
\[ \text{mult}_{\tilde{B}_1} C^1 \leq \text{mult}_{B_0} C \leq \frac{1}{2}(n(-K_S) - kl) \circ l = \frac{1}{2}(n - k), \]
so
\[ \tilde{\nu}_1 + \tilde{\nu}_2 \leq 2k + 2 \frac{n - k}{2} + m = n + k + m. \]
But $\tilde{\nu}_1 \geq \nu_1 + m$ and $\tilde{\nu}_2 \geq \nu_2$, thus
\[ 2n < \nu_1 + \nu_2 \leq n + k, \]
i.e., $k > n$, which is impossible.

So $B_1 \cap l^1 \neq \emptyset$. In order to show that $\nu_1 + \nu_2 \leq 3n$, we argue as before, only taking into account that
\[ \tilde{\nu}_1 + \tilde{\nu}_2 \leq 3k + \text{mult}_{B_0} C + \text{mult}_{\tilde{B}_1} C^1 + m. \]

We have $\nu_1 + \nu_2 \leq 2k + n \leq 3n$. The lemma is proved.

**Lemma 2.9.** Let $\varepsilon = 0$, $n_1 = 0$. Then $G_V \cong C \times \mathbb{P}^1$, where $C$ is an elliptic curve.
Proof. We use the notation of section 2.1. It is obvious that $G \cong C \times \mathbb{P}^1$. We shall prove the smoothness of $C$.

Notice that $R|_G \sim 3t_0$. Let $B$ be an irreducible component of $\text{Supp } R|_G$. Clearly, $B \sim t_0$. Let $\psi : \tilde{V} \to V$ be the blow-up of $B$ with the exceptional divisor $E$. $E$ is a ruled surface of the type $F_{n_2}$.

Denote $t_E$ and $l_E$ the classes of the exceptional section and a fiber of $E$ respectively. Then for strict transforms of the divisors $G$ and $R$ on $\tilde{V}$ we have (using their smoothness along $B$)

$$\tilde{G}|_E \sim t_E, \quad \tilde{R}|_E \sim t_E + n_2l_E,$$

hence $\tilde{G}|_E \cap \tilde{R}|_E = \emptyset$. So any fiber of $G \cong \mathbb{P}^1 \times \mathbb{P}^1$ meets $R$ transversally, i.e., at three different points. Thus, $C$ is nonsingular.

The lemma is proved. This completes also the proof of proposition 2.7.

Remark 2.10. In fact, proposition 2.7 works also in the case $n_1 = 0, n_2 = 1, n_3 = 2$, but the proof is more complicated. Since this case is non-rigid, satisfies theorem 2.6, and can not be advanced to a more complete description yet (see below), we omit proving of it.

Corollary 2.11. For $\varepsilon = n_1 > 0$, all smooth Mori fibrations on del Pezzo surfaces of degree 1 over $\mathbb{P}^1$ are rigid over the base; for $\varepsilon = 0$, all cases are also rigid, except the following:

a) $n_1 = n_2 = n_3 = 2$;
b) $n_1 = 0, n_2 = 1, n_3 = 2$.

Proof. Rigidity follows from proposition 2.7, using lemma 2.4 in the case $\varepsilon = 0$ or lemma 2.5 when $\varepsilon = n_1 > 0$.

We will deal with non-rigid cases after the following remark.

Remark 2.12. In [9] it was proved that (smooth) pencils of del Pezzo surfaces (of degree 1, 2 or 3) are all rigid, if the so-called $K^2$-condition holds:

$$\text{cycles } aK^2 - bf \text{ are not effective for any } a, b > 0.$$  

For degree 1, this condition is satisfied exactly when $n_2 \geq 4$ (for $\varepsilon = 0$) or $n_2 \geq 4 + \frac{3}{2}n_1$ (for $\varepsilon = n_1 > 0$). The second is always true except $n_1 = 2, n_2 = 6, n_3 = 12$.

Another sufficient condition of rigidity was proposed in [5] (conjecture 1.2):

$$(-K_V)^3 + m_0 + 1 \leq 2,$$

where

$$m_0 = \min \{ r \in \mathbb{Q} : (-K_V) + rF \text{ is nef} \}.$$
It holds exactly when $n_2 \geq 3$ ($\varepsilon = 0$) or $n_2 \geq 2 + \frac{3}{2}n_1$ ($\varepsilon = n_1 > 0$). Notice that the second is always true.

Thus, the second sufficient condition is more exact. Both these conditions do not include the rigid case $n_1 = 0$, $n_2 = 2$, $n_3 = 4$ for $\varepsilon = 0$.

Now we consider the non-rigid cases. We start with the case $n_1 = 0$, $n_2 = 1$, $n_3 = 2$. It was already considered in some works (see [5], section 2, §2, and [7]). It is easy to see that a unique effective divisor of the class $G_V$ is the direct product of $\mathbb{P}^1$ and an elliptic curve, the linear system $H = |2G_V + 2F| = |2(-K_V) - 2F|$ is base points free and defines a morphism contracting $G_V$ along $\mathbb{P}^1$ onto a curve $l$ on a Fano variety $U$ of index 2 and degree 5 (this is so-called the double cone over the Veronese surface). Indeed, the linear system $|M_Q|$ maps $Q$ onto a cone $\tilde{Q} \in \mathbb{P}^6$ over the Veronese surface in $\mathbb{P}^5$, and $U$ is obtained by taking the double cover branched along a cubic section that does not pass through the cone vertex. $l$ covers one of the generators of $\tilde{Q}$. Let

$$\mu : V = V_l \rightarrow U$$

be such a contraction. Notice that $-K_V \sim G_V + 2F$, and $V$ is a Fano itself. Thus, $V/\mathbb{P}^1$ is not rigid, and $1 = \alpha(V, H) < \mu(V, H) = 2$, i.e., the conditions of conjecture 1.6 hold. Notice that $U$ has a lot of such structures. Unfortunately, the technique of the maximal singularities method is not enough yet to deal completely with this case (for example, it fails when $l$ has a double point; see also remark 2.10). Nevertheless, we can formulate the following conjecture, which seems to be true:

**Conjecture 2.13.** Any smooth Mori fibration in the class of birational equivalence of $U$ is biregular to either $U$ or $V_l$ for some $l$.

The remaining case is $\varepsilon = 0$, $n_1 = n_2 = n_3 = 2$. Let $V/\mathbb{P}^1$ be the corresponding pencil of del Pezzo surfaces of degree 1. Notice that

$$N_{s_0|V} \simeq \mathcal{O}(-1) \oplus \mathcal{O}(-1)$$

and $|mH|$ for $m \gg 0$ gives a contraction of $s_0$. So there exists a flop

$$\mu : V \dashrightarrow U$$

centered at $s_0$. Then, dim $|G_V| = 1$:

$$2 \dim |G_V| = 2 \dim |G| \leq \dim |2G| = \dim |(M - 2L)|_Q = 2.$$
Proposition 2.14. Let \( \chi : V \rightarrow W \) be a birational map onto a Mori fibration \( \gamma : W \rightarrow S \). Then either \( \chi \) or \( \chi \circ \mu^{-1} : U \rightarrow W \) are birational over the base. Moreover, \( U \) and \( V \) are unique smooth Mori models in their class of birational equivalence; \( \text{Bir}(V) = \text{Aut}(V) \), and in general case, \( \text{Bir}(V) = (\sigma)_{\geq 2} \), where \( \sigma \) is the double cover involution.

Proof. Let \( D_W = |n'(\mathcal{K}_W) + \gamma^*(A)| \) be a very ample linear system, where \( A \) is an ample divisor on \( S \), and \( D_V = \chi^{-1}_* D_W \subset |n(\mathcal{K}_W) + mF| \).

Suppose \( m \geq 0 \). Then from proposition 1.2 it follows that \( n = n' \) and \( \chi \) is birational over the base. So we may assume \( m = -l < 0 \).

Denote \( D_U = \mu^{-1} D_V \). Since \( -K_U = G_U + F_U \), we have

\[ D_U \subset |(n-l)(-K_U) + lF_U|, \]

and \( \chi \circ \mu^{-1} \) is birational over the base by proposition 2.7.

Now let \( \chi : V \rightarrow W \) be a birational map onto a Mori fibration \( W/\mathbb{P}^1 \) with \( -K_W \) to be nef. We may assume \( \chi \) to be birational over the base. Suppose \( \mathcal{Y} = |n(-K_W) + m'F_W| \) is a very ample linear system, \( m' > 0 \), and \( D = \chi^{-1}_* \mathcal{Y} \subset |n(-K_V) + mF| \) for some \( m \geq 0 \). If \( K_V + \frac{1}{n} D \) were canonical, i.e., \( D \) had no maximal singularities, then \( \chi \) would be an isomorphism by proposition 1.2.

So let \( D \) have maximal singularities. We may assume that they are all infinitely near (see [9]). By \( Y \) and \( D \) we denote general elements of \( \mathcal{Y} \) and \( \mathcal{D} \) respectively. Choose a resolution of singularities of \( \chi \):

\[ Z \]

\[ \varphi \swarrow \searrow \psi \]

\[ V \xleftarrow{\chi} W \]

Notice that

\[ nK_Z + \psi^{-1}Y = m' \psi^*(F_W) + \sum a_i E'_i \]

and

\[ nK_Z + \varphi^{-1}D = m \varphi^*(F) + \sum b_i E_i, \]

where \( E'_i, E_i \) are exceptional divisors, \( a_i \) are all positive. Since \( D \) has maximal singularities, then

\[ \mathcal{M} = \{i : b_i < 0\} \]

is not empty. For a point \( t \in \mathbb{P}^1 \) we denote \( \mathcal{M}_t = \{i : \varphi(E_i) \in F_t\} \).

Obviously, \( \dim |nK_Z + \psi^{-1}Y| = m' \), so

\[ \dim |m \varphi^*(F) + \sum b_i E_i| = \dim |(m' + m - m') \varphi^*(F) + \sum b_i E_i| = m'. \]
Denote $I = \{ t \in \mathbb{P}^1 : \mathcal{M}_t \neq \emptyset \}$. Then there exists a split
\[ m - m' = \sum_{t \in I} k_t, \]
where $k_t$ are all positive, such that
\[ \dim \left| \sum_{t \in I} k_t \phi^{-1}(F_t) + \sum_{t \in I} \sum_{i \in \mathcal{M}_t} (k_t c_i - b_i) E_i \right| = 0, \]
where for $t \in I$ positive numbers $c_i$ are defined by
\[ \phi^*(F_t) = \phi^{-1}(F_t) + \sum_{i \in \mathcal{M}_t} c_i E_i. \]
So for any $t \in I$ and $i \in \mathcal{M}_t$ we have $k_t c_i - b_i \geq 0$, and, for every $i$, $k_i$ is the smallest positive number with such a property. Thus
\[ k_t = \max_{i \in \mathcal{M}_t} \lceil b_i c_i - 1 \rceil, \]
where $\lceil \rceil$ is the round up.

Let $D_1, D_2 \in \mathcal{D}$ be general. We can put down
\[ D_1 \circ D_2 = Z^h + Z^v \sim n^2 s + (2n^2 + 2mn) f, \]
where $Z^v$ and $Z^h$ are vertical and horizontal cycles. Since $s_0$ is unique in its class and centers of maximal singularities can not lie on $s_0$, then horizontal cycles being caught by at least one of these centers can put down as $A s_0 + B f$ for some $B \geq A$. Taking into account that
\[ m \leq m' + \sum_{t \in I} k_t, \]
we get an estimation
\[ \deg Z^v = \sum_{t \in \mathbb{P}^1} \deg Z^v_t \leq 2n^2 + 2mn - A \leq 2n^2 + 2m'n + 2n \sum_{t \in I} k_t - A \]
(the degrees of vertical cycles are estimated by intersection with $-K_V$).
Thus there exist $p \in I$ and $j \in \mathcal{M}_p$ such that
\[ \deg Z^v_p \leq 2n^2 + 2m'n + 2n \lceil b_j c_j^{-1} \rceil - A. \]
As in [9], §4, there exist positive numbers $\Sigma_0, \Sigma_1$, and $\Sigma'_0$, where $\Sigma_0 \geq \Sigma'_0$ and $c_j \geq \Sigma'_0$, such that the following inequality for multiplicities $m^h = \text{mult}_{B_0} Z^h$ and $m^v = \text{mult}_{B_0} Z^v_j$ of horizontal and vertical cycles at $B_0 = \phi(E_j)$ holds:
\[ (\Sigma_0 + \Sigma_1)(\Sigma_0 m^h + \Sigma'_0 m^v) \geq (2n \Sigma_0 + n \Sigma_1 + b_j)^2. \]
Notice that $\lceil b_j c_j^{-1} \rceil \Sigma_0 \leq b_j + \Sigma_0$. By lemma 2.8, $\mathcal{D}$ has an infinitely near singularity over the point $B_0 \in F_p$. Consider two cases.
1. \( B_1 \cap F'_1 = \emptyset \), i.e., the center of the second blow up in the chain realizing the maximal singularity, does not intersect the strict transform of the fiber. In this case, since \( B_1 \) is a point, we have \( \Sigma'_0 \leq \frac{1}{2} \Sigma_0 \). Then

\[
\Sigma'_0 m^v \leq 2 \deg Z'_p \frac{\Sigma_0}{2} \leq (2n^2 + 2m'n + 2n - A)\Sigma_0 + 2nb_j,
\]
and, using (2.2) and an estimation \( m^h \leq A \), we get

\[
n^2 - 2m'n - 2n < 0,
\]
i.e.,

\[
(2.3) \quad \frac{m'}{n} > \frac{1}{2} - \frac{1}{n}.
\]

2. Now let \( B_1 \cap S^1 \neq \emptyset \). Here we can not state that \( \Sigma'_0 \leq \frac{1}{2} \Sigma_0 \), but lemma 2.8 gives us a good estimation \( \nu_1 + \nu_2 \leq 3n \).

We know that \( m^h \leq A \) and

\[
\Sigma'_0 m^v \leq 2 \deg Z'_p \Sigma_0 \leq (4n^2 + 4m'n + 4n - 2A)\Sigma_0 + 4nb_j.
\]
Substituting this in (2.2), we obtain

\[
(A - 4m'n - 4n)\Sigma_0(\Sigma_0 + \Sigma_1) + (n\Sigma_1 - b_j)^2 < 0.
\]

Notice that a condition \( b_j > 0 \) is nothing but the Noether-Fano inequality ([10]): for some set of non-increasing numbers \( \{r_i\} \), where \( \sum r_i = \Sigma_0 + \Sigma_1 \), it holds

\[
b_j = \sum r_i \nu_i - 2n\Sigma_0 - n\Sigma_1 > 0.
\]
Applying \( \nu_1 + \nu_2 \leq 3n \), we get

\[
(n\Sigma_1 - b_j)^2 \geq \frac{1}{2} n^2 \Sigma_0(\Sigma_0 + \Sigma_1).
\]
Thus

\[
\frac{1}{2} n^2 + A - 4m'n - 4n < 0,
\]
and since \( A \geq 0 \), than

\[
(2.4) \quad \frac{m'}{n} > \frac{1}{8} - \frac{1}{n}.
\]
Comparing (2.3) and (2.4), we may assume that (2.4) holds always. It only remains to use the condition that \(-K_W\) is nef: we can choose \( Y \) such that \( n \) is big enough but \( m' = \frac{m'}{n} \) is as small as we want, and then get a contradiction because of (2.4).

Now, substituting \( U \) for \( W \), we obtain the statement about the birational automorphisms group. The uniqueness of smooth models of \( U \) and \( V \) follows from the description of all smooth (rigid and non-rigid) Mori fibrations on del Pezzo surfaces of degree 1 given above.
Proposition 2.14 is proved. This also completes corollary 2.11 and theorem 2.6.

3. Smooth varieties with a pencil of del Pezzo surfaces of degree 2.

3.1. The essential construction. In this section we study smooth Mori fibrations on del Pezzo surfaces of degree 2. Let \( \rho : V \to \mathbb{P}^1 \) be such a fibration. Denoting \( F \) the class of a fiber of \( \rho \), we have

\[
\text{Pic}(V) = \mathbb{Z}[-K_V] \oplus \mathbb{Z}[F]
\]

and \((-K_V)^2 \circ F = 2\). Since \( \rho \) is flat and \(-K_V\) is \( \rho \)-ample, for some integer \( m \) we have

\[
\rho_* \mathcal{O}(-K_V + mF) = \mathcal{E},
\]

where \( \mathcal{E} = \mathcal{O} \oplus \mathcal{O}(n_1) \oplus \mathcal{O}(n_2) \) is a vector bundle of rank 3 over \( \mathbb{P}^1 \), \( 0 \leq n_1 \leq n_2 \). Set

\[
X = \text{Proj} \ E
\]

with a natural projection \( \pi : X \to \mathbb{P}^1 \). By \( M \) we denote the class of the tautological bundle on \( X \), \( L \) the class of a fiber. Then

\[
\text{Pic}(X) = \mathbb{Z}[M] \oplus \mathbb{Z}[L].
\]

It is easy to see that there exists a double cover \( \varphi : V \to X \) branched along a smooth divisor \( R \) of the class \( 4M + 2aL \) such that

\[
\rho = \pi \circ \varphi.
\]

Further, let \( t_0 \) be the class of a section that corresponds to \( \mathcal{E} \to \mathcal{O} \to 0 \), \( l \) the class of a line in a fiber of \( \pi \), \( s_0 = \frac{1}{2} \varphi^*(t_0) \), and \( f = \frac{1}{2} \varphi^*(l) \). Then

\[
\overline{\text{NE}}(X) = \text{NE}(X) = \mathbb{R}_+[t_0] \oplus \mathbb{R}_+[l],
\]

\[
\overline{\text{NE}}(V) = \text{NE}(V) = \mathbb{R}_+[s_0] \oplus \mathbb{R}_+[f].
\]

Denote \( b = n_1 + n_2 \), \( H = \varphi^*(M) \); clearly, \( F = \varphi^*(L) \). We have \( M^2 = b \), \( M^2 = t_0 + bl \), \( K_X = -3M + (b - 2)L \), \( M \circ t_0 = L \circ l = 0 \), \( M \circ l = L \circ t_0 = 1 \), \( V: K_V = -H + (a + b - 2)F \), \( H^2 = 2s_0 + 2bf \), \( H \circ F = 2f \), \( H \circ s_0 = F \circ f = 0 \), \( H \circ f = F \circ s_0 = 1 \), \( (-K_V)^2 = 2s_0 + (8 - 4a - 2b)f \), \( H^3 = 2b \), \( (-K_V)^3 = 12 - 6a - 4b \) (see [5]).

Such varieties with \( K_V^2 = 2s_0 + \beta f \) for \( \beta \leq 0 \) were first studied in [9]. That was an exclusively important step in studying of geometry of Fano-fibered varieties.
3.2. Results about rigidity.

**Theorem 3.1.** Let $V/\mathbb{P}^1$ be a smooth Mori fibration on del Pezzo surfaces of degree 2 over $\mathbb{P}^1$ with $K_V^2 = 2s_0 + \beta f$, where $\beta \leq 2$ (i.e., $2a + b \geq 3$). Then $V/\mathbb{P}^1$ is birationally rigid.

**Proof.** Let $\chi : V \dashrightarrow V'$ be a birational map onto a Mori-fibration $\rho' : V' \to S'$, $D' = |-n'K_{V'} + \rho'^*A'|$ a linear system as in proposition 1.2, and $D = \chi^{-1}D' \subset |-nK_V + mF|$. We will denote $D$ a general element of $\mathcal{D}$. Obviously, $\mathcal{D}$ has no fixed components. If $n = n'$, the assertion follows from proposition 1.2. So let $n > n'$.

** Lemma 3.2.** $m \geq 0$, i.e. $\mu(D) = \alpha(D)$.

**Proof of the Lemma.** The cases $\beta \leq 0$ are proved in [9] (the so-called $K^2$-condition holds in these cases). Let $\beta = 2$. Then $2a + b = 3$, $b$ is odd, so $n_1 < n_2$. Clearly, $\mu(D) = n$.

Assume the converse, i.e., $m < 0$. Consider a general curve $C \sim 2s_0 + 2n_1f$ on $V$ (there is at least 1-dimensional family of such curves). Then for general $D$ we have $D \circ C \geq 0$, so

$$(nH - (\frac{n}{2}(b - 1) - m)F) \circ (s_0 + n_1f) \geq 0,$$

and we get a contradiction:

$$0 < -\frac{m}{n} \leq n_2 - \frac{b}{2} + \frac{1}{2} = \frac{n_1 - n_2 + 1}{2} \leq 0.$$

The lemma is proved.

By the lemma, we may assume $m \geq 0$. The following argumentation proving the theorem is nearly the same as in [9].

Obviously, $\mathcal{D}$ is not canonical, so it has maximal singularities. Let a curve $B$ be the center of a maximal singularity. Then $B$ is a section of $\rho$ not lying on the ramification divisor, and we can ”untwist” such a maximal singularity using the Bertini involution centered at $B$.

So we assume that the center of any maximal singularity is a point. Set $D_1 \circ D_2 = Z^h + Z^v$, where $Z^h$ and $Z^v$ are horizontal and vertical (effective) cycles. We see that

$$Z^h + Z^v = 2s_0 + (\beta n^2 + 4mn)f.$$

Denote $\deg Z^h \overset{\text{def}}{=} Z^h \circ F$ and $\deg Z^v \overset{\text{def}}{=} Z^v \circ (-K_V)$. Then, there exist a discrete valuation $\nu$ centered over a point $B_0$ in a fiber $F_t$ (over a point $t \in \mathbb{P}^1$), a positive number $e = \nu(\mathcal{D}) - n\delta$, where $\delta$ is the canonical multiplicity with respect to $\nu$, such that a component $Z^v_t$ of $Z^v$ lying
in $F_t$ has the degree

$$\deg Z_i^v < \begin{cases} 
\beta n^2 + 4n \frac{e}{v(F_t)}, & \text{if } \beta > 0; \\
4n \frac{e}{v(F_t)}, & \text{if } \beta \leq 0.
\end{cases}$$

Notice that $m^h \overset{\text{def}}{=} \text{mult}_{B_0} Z^h \leq \deg Z^h = 2n^2$ and $m^v \overset{\text{def}}{=} \text{mult}_{B_0} Z_i^v \leq \deg Z_i^v$. Then, there exist positive numbers $\Sigma_0 \geq \Sigma_0'$ and $\Sigma_1$ such that the following inequality holds:

$$(\Sigma_0 + \Sigma_1)(m^h \Sigma_0 + m^v \Sigma_0') > (2n \Sigma_0 + n \Sigma_1 + e)^2.$$ 

It only remains to substitute the estimations of $m^h$ and $m^v$:

$$(\Sigma_0 + \Sigma_1)((2 + \beta n^2)\Sigma_0 + 4ne) > (2n \Sigma_0 + n \Sigma_1 + e)^2,$$

i.e.,

$$(2 - \beta)n^2 \Sigma_0(\Sigma_0 + \Sigma_1) + (n \Sigma_1 - e)^2 < 0,$$

which is impossible, if $\beta \leq 2$. Theorem 3.1 is proved.

Now we shall consider smooth Mori fibrations on del Pezzo surfaces of degree 2 for $2a + b \leq 2$. First, let $2a + b = 2$, i.e., $K_V^2 = 2s_0 + 4f$.

**Lemma 3.3.** For $2a + b = 2$, the only following cases may occur:

1) $a = -1$, $n_1 = n_2 = 2$;
2) $a = 1$, $n_1 = n_2 = 0$;
3) $a = 0$, $n_1 = n_2 = 1$;
4) $a = 0$, $n_1 = 0$, $n_2 = 2$;
5) $a = -2$, $n_1 = 2$, $n_2 = 4$;
6) $a = -3$, $n_1 = 2$, $n_2 = 6$;
7) $a = -4$, $n_1 = 2$, $n_2 = 8$;

The first three cases are non-rigid.

**Proof.** Since $b \geq 0$, the only cases 2), 3), and 4) are possible if $a \geq 0$.

Let $a < 0$. Then $b > 0$, and since $R \circ t_0 < 0$, any curve of the class $s_0$ lies on $R$. So $n_1 > 0$ because of irreducibility of $R$, and such a curve is unique on $X$. Further, let $\psi : \tilde{X} \to X$ be the blow-up of $t_0$ with $E$ as an exceptional divisor. $E$ is a ruled surface of the type $\mathbf{F}_{n_2-n_1}$. By $t_E$ and $l_E$ we denote the classes of an exceptional section and a fiber of $E$. Suppose $\tilde{R}$ is the strict transform of $R$, then

$$\tilde{R}|_{t_E} \sim t_E + (2a + n_2)l_E$$

is an irreducible curve on $V$ because of the smoothness of $R$. So either $2a+n_2 = 0$, or $2a+n_2 \geq n_2-n_1$. It is easy to check that the second case is possible only if $n_1 = n_2 = 2$ and $a = -1$. Further, if $2a + n_2 = 0$, then $n_1 = 2$. Moreover, curves of the class $t_0 + n_1 l$ lie on a unique effective divisor of the class $M - n_2 L$, and since $R$ is irreducible, we have $R \circ (t_0 + n_1 l) \geq 0$, whence $a \geq -4$. 

Now we show that the first three cases are non-rigid. Let $a = 1$, $n_1 = n_2 = 0$. We see that $X \cong \mathbb{P}^2 \times \mathbb{P}^1$, and $V$ is a conic bundle with respect to the projection onto $\mathbb{P}^2$: double covers of curves of the class $t_0$ are conics since $R \circ t_0 = 2$. So $V$ is non-rigid. Notice that this projection is given by a linear system $|-K_V - F|$, which is free from base points.

Let $a = -1$, $n_1 = n_2 = 2$. A unique curve of the class $t_0$ on $X$ lies on the ramification divisor $R$, so $s_0$ is unique on $V$, too. Note that

\[ \mathcal{N}_{s_0|V} = \mathcal{O}(-1) \oplus \mathcal{O}(-2) \]

and $|nH|$ for $n \geq 2$ gives a birational morphism contracting $s_0$. Then, the base set of the pencil $|M - L|$ is exactly $s_0$; all elements of this pencil are smooth and isomorphic to $\mathbf{F}_2$. For a general $S \in |M - L|$ the restriction $R|_S$ is composed from $s_0$ and some three-section that does not intersect $s_0$, so after taking the double cover and contracting the pre-image of $s_0$ the surface $S$ becomes a del Pezzo surface of degree 1. This means that the anti-flip $V/\mathbb{P}^1 \dashrightarrow V'/\mathbb{P}^1$ (centered at $s_0$) gives us a Mori fibration on del Pezzo surfaces of degree 1 with a terminal singular point lying on the exceptional curve of $V'$. Thus, $V/\mathbb{P}^1$ is not rigid. Note that the pencil $|-K_V - F|$ has no fixed components.

Finally, for $a = 0$, $n_1 = n_2 = 1$ the linear system $| -2K_V |$ gives a small contraction onto the canonical model of $V$, which can be realized as double covering of a non-degenerated quadratic cone in $\mathbb{P}^4$ branched along a quartic section. If a curve of the class $s_0$ is unique on $V$ (this means that $t_0$ lies on the ramification divisor), then $s_0$ is -2-curve of the width 2 (in the notions of [11]). Otherwise, there are two curves of the class $s_0$, which are disjoint and -2-curves of the width 1. In both the cases we obtain another structure of a smooth Mori fibration on del Pezzo surfaces of degree 2 after making a flop centered at these curves. Notice again that $|-K_V - F|$ has no fixed components. The case of two curves was studied in detail in [3].

Lemma 3.3 is proved.

**Remark 3.4.** It is highly likely that cases 4) – 7) are all rigid. Unfortunately, the author can not prove it yet. As it often occur in the practice of the maximal singularity method, the problems are related to excluding of infinitely near singularities over points on some rational curves of a special kind.

Now we consider cases when $2a + b = 1$, i.e., $K_V^2 = 2s_0 + 6f$.

**Lemma 3.5.** If $2a + b = 1$, the only following three cases may occur:

1) $a = 0$, $n_1 = 0$, $n_2 = 1$;
2) $a = -1$, $n_1 = 1$, $n_2 = 2$;
3) \( a = -2, n_1 = 1, n_2 = 4. \)

The first two are non-rigid.

Proof. Arguing as before, it is easy to show that \( a \geq -2 \), so the only 1) – 3) are possible.

In order to show that the case 1) is non-rigid, note that \( V \) can be obtained by blowing up of an elliptic curve of degree 2 on a smooth Fano variety \( U \) of genus 9 and index 2 (this is so-called the double space of index 2, i.e., the double cover of \( \mathbb{P}^3 \) branched along a quartic). Observe that the birational morphism \( V \rightarrow U \) is defined by the linear system \( |-2K_V - 2F| \). Some results (but very incomplete) about these varieties are contained in [8].

Consider the case \( a = -1, n_1 = 1, n_2 = 2. \) There exists a unique curve of the class \( s_0 \), and it is a -2-curve of the width 1. Let \( V \rightarrow V^+ \) be a flop centered at this curve. A linear system \( |H - 2F| \) contains a unique element, which we denote \( G_V \). Its strict transform \( G^+_V \) on \( V^+ \) is a surface that is isomorphic to the double cover of \( \mathbb{P}^2 \) branched along either a smooth conic or a couple of different lines. So \( G^+_V \) is either \( \mathbb{P}^1 \times \mathbb{P}^1 \), or a quadratic cone in \( \mathbb{P}^3 \). Then, there exists an extremal contraction \( V^+ \rightarrow U \) of \( G^+_V \). U is a double cone over the Veronese surface, but with a quadratic singularity (arising from a quadratic singularity of the ramification divisor). We see also that \( U \) has (birationally) structures of fibrations on del Pezzo surfaces of degree 1 (see section 2, the case \( n_1 = 0, n_2 = 1, n_3 = 2. \)) Notice that \( |-K_V - F| \) has no fixed components.

The lemma is proved.

As after lemma 3.3, the author can say the same thing about the case 3): it should be rigid, but I can not prove it yet.

We complete this survey of del Pezzo fibrations by the following lemma:

**Lemma 3.6.** Cases \( 2a + b \leq 0 \) can not occur.

Proof. The same reasons as above, except the case \( a = 0. \) If \( a = 0, \) then \( b = 0, \) so \( V \) is isomorphic to the direct product of \( \mathbb{P}^1 \) and a smooth del Pezzo surface of degree 2. But in this case \( V \) is not a Mori fibration because of the relative Picard number (it is equal to 8). The lemma is proved.
