Abstract
We generalize Hamilton’s principle with fractional derivatives in the Lagrangian $L(t, y(t), \frac{D^\alpha y(t)}{D^t}, \alpha)$ so that the function $y$ and the order of the fractional derivative $\alpha$ are varied in the minimization procedure. We derive stationarity conditions and discuss them through several examples.

1. Introduction

Hamilton’s principle is one of the basic principles of theoretical physics, where theory is often considered to be complete if its variational principle in the sense of Hamilton is known [4]. When Hamilton’s principle is known, the information regarding the processes of a particular system is included into its Lagrangian. It could serve as a basis for obtaining first integrals via Noether’s theory, or to generate approximate solutions to the relevant system of equations by the use of the Ritz procedure (cf [30]).

In this paper we investigate necessary conditions for the existence of solutions of fractional variational problems (Euler–Lagrange equations) by the use of a generalized Hamilton’s principle. Such investigations have been initiated in [25, 26], and continued in [1–5] and [8]; see also [24] for the importance of introducing fractional derivatives into the Lagrangian density of Hamilton’s principle. In general, we refer to [9–16], [19, 22, 23] and [27–31] for different aspects of the calculus of variations and fractional calculus, motivations and applications.

When a fractional variational problem is studied, a natural question arises how can one choose $\alpha$, the order of fractional derivative, in order to achieve the minimal value of a
functional under consideration. More generally, one can address the same question for any problem involving fractional operators. Usually, in application, a good choice of $\alpha$ is obtained by experiments or computational simulations. However, experimental results are theoretically not well confirmed. In this paper we propose a method which \textit{a priori} gives values for $\alpha$ which optimize the considered variational problem following the fundamental minimization principle of Hamilton’s action. In fact, we address the question of finding stationary points for Hamilton’s action integral with fractional Lagrangian in a more general setting: we allow the stationarity of the action integral with respect to a set of admissible functions and with respect to the order of fractional derivatives, appearing in the Lagrangian. To our knowledge the problem when both $y$ and $\alpha$ are varied has not been analyzed so far. It leads to stationarity conditions as a basis for a generalized Hamilton’s principle for the action integral

$$I[y, \alpha] := \int_0^b L(t, y(t), 0D_t^\alpha y, \alpha) \, dt, \quad y \in \mathcal{U}, \alpha \in A := [0, \alpha_0], \quad \alpha_0 < 1,$$

where $\mathcal{U}$ is a set of admissible functions: find

$$\min_{(y, \alpha) \in \mathcal{U} \times A} I[y, \alpha] \quad (2)$$

or

$$\min_{\alpha \in A} (\min_{y \in \mathcal{U}} I[y, \alpha]) \quad (3)$$

or

$$\min_{y \in \mathcal{U}} (\min_{\alpha \in A} I[y, \alpha]). \quad (4)$$

In this paper we analyze stationarity conditions for (2) and (3). Stationarity conditions with respect to $\alpha$ in (4) are more difficult, and, contrary to (3), this case is less natural in applications. Note that in (2), (3) and (4) one can look for maximums instead of minimums. So, our general problem is the determination of stationary points.

The paper is organized as follows. In the introduction we recall the definitions and properties of fractional derivatives. In section 2 we present a framework in which we shall study variational problems (2) and (3). Then in section 3 we derive stationarity conditions for (2). Section 4 is devoted to additional assumptions which provide equivalence of problems (2) and (3). Results which are obtained in the previous sections are illustrated by several examples in section 5. Moreover, examples of this section give further motivation for our investigation. In the last remark of section 5 we propose a new formulation of a fractional variational problem.

Throughout this paper we shall use the following notation. The mapping $(t, \alpha) \mapsto 0D_t^\alpha y(t)$, which defines the left Riemann–Liouville fractional derivative of order $\alpha$, will be denoted by $0D_t^\alpha y$, or by $0D_t^\alpha y(t)$. Recall that

$$0D_t^\alpha y := \frac{1}{\Gamma(1-\alpha)} \frac{d}{dt} \int_0^t \frac{y(\tau)}{(t-\tau)^\alpha} \, d\tau, \quad t \in [0, b], \quad 0 \leq \alpha < 1,$$

where $\Gamma$ is the Euler gamma function, and its existence is provided whenever

$$[0, b] \ni t \mapsto \int_0^t \frac{y(\tau)}{(t-\tau)^\alpha} \, d\tau$$

is an absolutely continuous function. Recall that the space of absolutely continuous functions is denoted by $AC([0, b])$ and is supplied with the norm $\|f\| = \sup_{t \in [0, b]} |f(t)|$ (clearly, it is not a Banach space). For example, (5) is absolutely continuous if $y \in AC([0, b])$. However, there are some cases when with less regularity in $y$ we still have a well-defined operator of fractional differentiation (cf [27]). For instance, $0D_t^\alpha y$ exists for functions with integrable singularities
fractional derivative of order $\alpha$ of a continuous and locally integrable function $f$ in $(0, b]$ has an integrable singularity at $\tau = 0$ of order $r < 1$ if $\lim_{\tau \to 0^+} \tau^r f(\tau) \neq 0$. In particular, we can take $y(t) = t^{-\mu}$, $t \in (0, b]$ (for any $b > 0$), $0 < \mu < 1$. Then we obtain the so-called Euler formula (cf [27, (2.26)])

$$0 D_0^\alpha t^{-\mu} = \frac{\Gamma(1 - \mu)}{\Gamma(1 - \mu - \alpha) t^{\mu+\alpha}}, \quad t \in (0, b].$$

The right Riemann–Liouville fractional derivative of order $\alpha$ is defined as

$$1 D_b^\alpha y := \frac{1}{\Gamma(1 - \alpha)} \int_t^b y(\tau) \left( -\frac{d}{d\tau} \right) \left( \frac{d}{d\tau} \right)^{1 - \alpha} \tau^\alpha \, d\tau, \quad t \in [0, b], \quad 0 \leq \alpha < 1.$$

The conditions for its existence are similar as in the case of the left fractional derivative.

In the following we shall consider cases involving both fractional derivatives and work with integrable functions which can take values $+\infty$ or $-\infty$ at some points. Recall [21] that $0 D_0^\alpha y \to y'$ and $1 D_b^\alpha y \to -y'$ in $C([0, b])$, as $\alpha \to 1^-$, whenever $y \in C^1([0, b])$.

Also, we shall make use of Caputo fractional derivatives. The left, resp. right, Caputo fractional derivative of order $\alpha \in [0, 1)$ is defined as

$$\frac{C}{0} D_0^\alpha y := \frac{1}{\Gamma(1 - \alpha)} \int_0^t y'(\tau) \left( \frac{d}{d\tau} \right)^{1 - \alpha} \tau^\alpha \, d\tau \quad \text{resp.} \quad \frac{C}{1} D_b^\alpha y := \frac{1}{\Gamma(1 - \alpha)} \int_t^b -y'(\tau) \left( \frac{d}{d\tau} \right)^{1 - \alpha} \tau^\alpha \, d\tau.$$

One can show that for $y \in AC([0, b])$ and $t \in [0, b],$

$$0 D_t^\alpha y = \frac{C}{0} D_0^\alpha y + \frac{1}{\Gamma(1 - \alpha)} y(0), \quad 1 D_b^\alpha y = \frac{C}{1} D_b^\alpha y + \frac{1}{\Gamma(1 - \alpha)} y(b),$$

(cf e.g. [17]). Therefore, $0 D_t^\alpha y = \frac{C}{0} D_0^\alpha y$, resp. $1 D_b^\alpha y = \frac{C}{1} D_b^\alpha y$, whenever $y(0) = 0$, resp. $y(b) = 0$.

2. Formulation of the problem

We investigate stationary points of (1) for $\alpha \in [0, \alpha_0]$ and all admissible functions $y$, whose properties will be specified in the sequel. We shall distinguish two cases: $\alpha_0$ strictly less than 1 and $\alpha_0 = 1$. In the case $\alpha_0 < 1$, set

$$\mathcal{U}_t := \{ y \in L^1([0, b]) \mid 0 D_t^\alpha y \in L^1([0, b]) \}. $$

Obviously, $AC([0, b])$ is a subset of $\mathcal{U}_t$. In the case $\alpha_0 = 1$ we assume that $y \in \mathcal{U}_t$ and that, in addition, $0 D_t^\alpha y$ exists, and $0 D_t^\alpha y = y'$ is an integrable function. Let us note that one can consider $\mathcal{U}_t$ defined with $L^p([0, b])$ (or their subspaces) instead of $L^1([0, b])$ (see remark 3.3).

In general, we shall use the notation

$$\mathcal{U} := \{ y \in \mathcal{U}_t \mid y \text{ satisfies specified boundary conditions} \}.$$  

We shall sometimes write $\mathcal{U}$ also for $\mathcal{U}_t$ (then the set of specified boundary conditions is empty).

In the following, the Lagrangian $L(t, y(t), 0 D_t^\alpha y, \alpha)$ (Lagrangian density, in physics) satisfies:

$$L \in C^1([0, b] \times \mathbb{R} \times \mathbb{R} \times [0, 1])$$

and

$$t \mapsto \partial_3 L(t, y(t), 0 D_t^\alpha y, \alpha) \in \mathcal{U}_t, \quad \text{for every } y \in \mathcal{U}_t,$$

where $\mathcal{U}_t := \{ y \in L^1([0, b]) \mid 0 D_t^\alpha y \in L^1([0, b]) \}$. 

3
Recall that our generalization of Hamilton’s principle is realized through the determination of \((y^*, \alpha^*) \in \mathcal{U} \times A\) such that
\[
\min_{(y, \alpha) \in \mathcal{U} \times A} \int_0^b L(t, y(t), \alpha) \, dt = \int_0^b L(t, y^*(t), \alpha^*) \, dt.
\] (8)

There are two special cases of (8). The first one is obtained when \(A = \{1\}\). Then, since \(0D_0^\alpha y |_{\alpha = 1} = y'(t)\) for \(y \in C^1([0, b])\), the solution \(y^*\) of (8) satisfies the classical Euler–Lagrange equation
\[
d \frac{\partial L}{\partial y} - \frac{\partial L}{\partial y'} = 0.
\]

If \(A\) has a single element \(A = \{\alpha\}, 0 < \alpha < 1\), then \(\min_{(y, \alpha) \in \mathcal{U} \times \{\alpha\}} I[y, \alpha]\) leads to the fractional Euler–Lagrange equation (cf \([1, 5]\))
\[
tD_{\alpha} b \frac{\partial L}{\partial 0D_{\alpha} t y} + \frac{\partial L}{\partial y} = 0.
\]

We proceed with finding stationary points related to (1).

### 3. Optimality conditions

A necessary condition for the existence of solutions to the variational problem (8) is given in the following proposition.

**Proposition 3.1.** Let \(L\) satisfy (7). Then a necessary condition that functional (1) has an extremal point at \((y^*, \alpha^*) \in \mathcal{U} \times A\) is that \((y^*, \alpha^*)\) is a solution of the system of equations
\[
\frac{\partial L}{\partial y} + D_0^\alpha \frac{\partial L}{\partial D_0^\alpha y} = 0,
\]
\[
\int_0^b \left( \frac{\partial L}{\partial D_0^\alpha y} G(y, \alpha) + \frac{\partial L}{\partial \alpha} \right) \, dt = 0,
\]
where
\[
G(y, \alpha) = \frac{\partial D_0^\alpha y}{\partial \alpha} = \frac{d}{dt} (f_1 \ast y)(t, \alpha), f_1(t, \alpha) = \frac{1}{\Gamma(1 - \alpha)} [\psi(1 - \alpha) - \ln t], \quad t > 0,
\]
with the Euler function \(\psi(z) = \frac{d}{dz} \ln \Gamma(z)\), and \((f_1 \ast y)(t, \alpha) = \int_0^t f_1(t, \alpha) y(t - \tau) \, d\tau\).

**Proof.** Let \((y^*, \alpha^*)\) be an element of \(\mathcal{U} \times A\) for which \(I[y, \alpha]\) has an extremal value. Let \(y(t) = y^*(t) + \varepsilon_1 f(t), \alpha = \alpha^* + \varepsilon_2, \varepsilon_1, \varepsilon_2 \in \mathbb{R},\) with \(f \in \mathcal{U}\), and the boundary conditions on \(f\) are specified so that the varied path \(y^* + \varepsilon_1 f\) is an element of \(\mathcal{U}\). Then \(I[y, \alpha] = I[y^* + \varepsilon_1 f, \alpha^* + \varepsilon_2] = I(\varepsilon_1, \varepsilon_2)\). A necessary condition for an extremal value of \(I[y, \alpha]\) is
\[
\frac{\partial I(\varepsilon_1, \varepsilon_2)}{\partial \varepsilon_1}(\varepsilon_1 = 0, \varepsilon_2 = 0) = \frac{\partial I(\varepsilon_1, \varepsilon_2)}{\partial \varepsilon_2}(\varepsilon_1 = 0, \varepsilon_2 = 0) = 0.
\]

Therefore we obtain
\[
\int_0^b \left( \frac{\partial L}{\partial y} f(t) + \frac{\partial L}{\partial D_0^\alpha y} 0D_0^\alpha f \right) \, dt = 0,
\]
\[
\int_0^b \left( \frac{\partial L}{\partial D_0^\alpha y} \frac{\partial 0D_0^\alpha y}{\partial \alpha} + \frac{\partial L}{\partial \alpha} \right) \, dt = 0.
\]
Applying the fractional integration by parts formula (cf [17]):

$$\int_0^b g(t) \cdot 0^{\alpha} D_t f(t) \, dt = \int_0^b f(t) \cdot D_t 0^{\alpha} g(t) \, dt,$$

(13)
to (11), (11) is transformed into

$$\int_0^b \left( \frac{\partial L}{\partial y} + 0^{\alpha} D_t \frac{\partial L}{\partial 0^{\alpha} D_t y} \right) f(t) \, dt = 0,$$

From this equation, using the fundamental lemma of the calculus of variations (see [9, p 115]), we conclude that condition (9) holds for the optimal values $y^*$ and $\alpha^*$. In (10) the term $\frac{\partial_0 D_t y}{\partial \alpha}$ is transformed by the use of the expression

$$\frac{\partial_0 D_t y}{\partial \alpha} = \psi(1 - \alpha) 0^{\alpha} D_t y - \frac{1}{\Gamma(1 - \alpha)} \frac{d}{dt} \int_0^t \frac{\ln(t - \tau)y(t)}{(t - \tau)^\alpha} \, d\tau,$$

(cf [6, p 592]). We obtain (10) by substituting (14) into (12).

**Remark 3.2.** In general, while solving equations (9) and (10), the most delicate task is the calculation of the expression $\frac{\partial_0 D_t y}{\partial \alpha}$. Although its general form (14) has been derived in [6, p 592], various difficulties can still appear. We illustrate this by examples in section 5. However, the simplified form of $\frac{\partial_0 D_t y}{\partial \alpha}$ in some special cases, is important. Already in [6] it has been shown that for $y \in AC([0, b])$

$$\frac{\partial_0 D_t y}{\partial \alpha} \bigg|_{\alpha = 0^+} = -(\gamma + \ln t)y(0) - \int_0^t (\gamma + \ln \tau)y(t - \tau) \, d\tau$$

$$= -(\gamma + \ln t)y(t) + \int_0^t \frac{y(t) - y(t - \tau)}{\tau} \, d\tau,$$

(15)

where $\gamma = 0.5772156 \ldots$ is the Euler constant. (Another form of $\frac{\partial_0 D_t y}{\partial \alpha} \bigg|_{\alpha = 0^+}$ is also given in [31, p 111].)

Let us obtain a simplified form of $\frac{\partial_0 D_t y}{\partial \alpha} \bigg|_{\alpha = 0^+}$ at $\alpha = 1^-$. In order to do that we use the method proposed in [28]. We recall the expansion of $(t - \tau)^{\alpha} / \Gamma(1 + \varepsilon)$ with respect to $\varepsilon$, at $\varepsilon = 0$, with $\tau < t$ (cf [28, p 401]), which will be used in the following:

$$\frac{(t - \tau)^{\varepsilon}}{\Gamma(1 + \varepsilon)} = e^{\varepsilon \ln(t - \tau)} \frac{\Gamma(1 + \varepsilon)}{\Gamma(1 + \varepsilon)} = 1 + \varepsilon(\gamma + \ln(t - \tau)) + o(\varepsilon).$$

(16)

Now assume that $y \in C^2([0, b])$. Then, as in [23], for $t \in [0, b]$,

$$0_D_t y = \frac{1}{\Gamma(1 - \alpha)} \frac{d}{dt} \int_0^t \frac{y(\tau)}{(t - \tau)^\alpha} \, d\tau$$

$$= \frac{y(0)}{\Gamma(1 - \alpha) t^\alpha} + \frac{1}{\Gamma(1 - \alpha)} \int_0^t \frac{y(1)(\tau)}{(t - \tau)^\alpha} \, d\tau$$

$$= \frac{y(0)}{\Gamma(1 - \alpha) t^\alpha} + \frac{y(1)(0)}{\Gamma(2 - \alpha) t^{\alpha - 1}} + \frac{1}{\Gamma(2 - \alpha)} \int_0^t (t - \tau)^1 y(2)(\tau) \, d\tau.$$

With $\alpha = 1 - \varepsilon$ we obtain

$$0_D_t^{1 - \varepsilon} y = \frac{y(0)}{\Gamma(\varepsilon) t^{1 - \varepsilon}} + \frac{y(1)(0)t^\varepsilon}{\Gamma(1 + \varepsilon)} + \frac{1}{\Gamma(1 + \varepsilon)} \int_0^t (t - \tau)^{\varepsilon} y(2)(\tau) \, d\tau.$$
From (17) and (16) it follows that
\[
\frac{\partial_0 D^\alpha_y}{\partial \alpha}_{\alpha=1^-} = -\frac{\partial_0 D^{1-\varepsilon}_y}{\partial \varepsilon}|_{\varepsilon=0} = -\frac{y(0)}{t} - y^{(1)}(0) \ln t - y^{(1)}(t) - \int_0^t y^{(2)}(\tau) \ln(t - \tau) \, d\tau.
\] (18)

Assuming \(y(0) = 0\) in (18), we recover the results presented in [28] and [29] for the Caputo fractional derivative. Since \(0D^\alpha_0 y = \mathcal{C} D^\alpha_0 y\) when \(y(0) = 0\), it follows that with \(y(0) = 0\) (18) becomes
\[
\frac{\partial_0 D^\alpha_y}{\partial \alpha}_{\alpha=1^-} = -\frac{y(0)}{t} - y^{(1)}(0) \ln t - y^{(1)}(t) - \int_0^t y^{(2)}(\tau) \ln(t - \tau) \, d\tau.
\]

**Remark 3.3.** Functional (1) is a special case of the class of functionals with Lagrangians depending on linear operators, see [12, p 51]. Indeed, suppose that the Lagrangian \(L\) satisfies (7). Assume that for every \(y \in \mathcal{A}(t, y(t), \mathcal{L}y(t)), y(t)\) is continuous, for all \(y \in M\). Then the Euler–Lagrange equation reads
\[
\frac{\partial L}{\partial y} + \mathcal{L}^* \frac{\partial L}{\partial (\mathcal{L}y)} = 0,
\]
where \(\mathcal{L}^*\) denotes the adjoint operator of \(\mathcal{L}\). In the case when \(\mathcal{L}\) is the left Riemann–Liouville operator \(0D^\alpha_0\), with the adjoint \(D^\alpha_0\), the latter equation coincides with (9).

If instead of \(\mathcal{L}\) one considers a family \(\{\mathcal{L}_\alpha, \alpha \in A\}\), where \(A = [0, 1]\) (or some other interval), and the mapping \(A \to \text{Lin}(M, L^p([0, b])), \alpha \mapsto \mathcal{L}_\alpha\), is differentiable, then a more general problem of finding stationary points with respect to \(y\) and \(\alpha\) can be formulated. In that case, one can derive the second stationarity condition similar to (10):
\[
\int_0^b \left(\frac{\partial L}{\partial \mathcal{L}} \frac{\partial \mathcal{L}}{\partial \alpha} + \frac{\partial L}{\partial \alpha}\right) \, d\tau = 0.
\]

**4. Equivalent problems**

In this section we shall give conditions which show that problems (2) and (3) coincide.

**Proposition 4.1.** Let the Lagrangian \(L\) satisfy (7). Assume that for every \(\alpha \in [0, 1]\) there is a unique \(y^*(t, \alpha) \in \mathcal{U}\), a solution to (9), and that the mapping \(\alpha \mapsto y^*(t, \alpha)\) is differentiable as a mapping from \(0, 1\) to \(\mathcal{U}\). Then the problem \(\min_{(y, \alpha) \in \mathcal{U} \times A} I[y, \alpha]\) is equivalent to the problem \(\min_{\alpha \in A} (\min_{y \in \mathcal{U}} I[y, \alpha])\).

**Proof.** As we have shown in proposition 3.1, any solution to the problem \(\min_{(y, \alpha) \in \mathcal{U} \times A} I[y, \alpha]\) satisfies the system (9)–(10). It can be solved as follows. We first solve (9) and the corresponding boundary conditions to obtain \(y^* = y^*(t, \alpha)\). According to the assumption, the solution \(y^*\) is unique. Then we insert \(y^*\) in (10) to obtain \(\alpha^*\). In this case, the functional
I[y, α] becomes a functional depending only on α, α ↦ I[y*(t, α), α] = I[α], and therefore (10) transforms into the total derivative of I[α] since
\[ \frac{dI[α]}{dα} = \frac{dI[α + ε]}{dε} \bigg|_{ε=0} \]
\[ = \int_0^1 \left[ \frac{∂L}{∂y} \frac{∂y}{∂α} + \frac{∂L}{∂D^α_t y} \frac{∂D^α_t y}{∂α} \right] dt \]
\[ = \int_0^1 \left[ \frac{∂y}{∂α} \frac{∂L}{∂y} + 0 + \frac{∂L}{∂D^α_t y} \frac{∂D^α_t y}{∂α} \right] dt \]
\[ = \int_0^1 \left[ \frac{∂L}{∂D^α_t y} \left( \frac{∂}{∂α} D^α_t y \right) y + \frac{∂L}{∂α} \right] dt, \quad (19) \]
where we used fractional integration by parts formula (13) in the third, and equation (9) in the last equality. This proves the claim.

The following simple assertion is of particular interest.

**Proposition 4.2.** Let L satisfy (7). Assume that for every α ∈ [0, 1] there exists a unique yα ∈ U, a solution to the fractional variational problem (8), and that I[yα, α] is the corresponding minimal value of the functional I. Assume additionally that
\[ \frac{dI}{dα}(y, α)|_{y=yα} > 0, \quad ∀yα ∈ U. \]
Then the minimal and maximal value of the functional I[y, α] is attained at α = 0 resp. at α = 1.

**Proof.** Under the above assumptions we have that
\[ I[y_0, 0] \leq I[y_α, 0] \leq I[y α, α] \leq I[y_1, α] \leq I[y_1, 1], \quad ∀α ∈ [0, 1], \]
which proves the claim. □

**Remark 4.3.** The same argument can be applied to the case when dI/dα < 0, for any fixed yα ∈ U, i.e. when I is a decreasing function of α, for any fixed yα ∈ U. In that case the minimal and maximal value of I is at α = 1, resp. α = 0.

5. Examples

5.1. Examples with Lagrangians linear in y

**Example 5.1.** Consider the action integral for the inertial motion (no force acting) of a material point of the form
\[ I[y, α] := \int_0^1 \left( a D^α_t y \right)^2 dt, \quad (y, α) ∈ U × A, \quad (20) \]
where U := [y ∈ U | y(0) = 0, y(1) = 1] and A = [0, 1].

Obviously, the minimal value of I[y, α] is zero, and it is attained whenever a D^α_t y = 0. Solutions to the equation \( a D^α_t y = 0 \) are of the form \( y(t) = C \cdot t^{1-α} \), \( t ∈ [0, 1] \), \( C ∈ ℝ \) (cf [27]). All solutions satisfy the Euler–Lagrange equation
\[ i D^α_t (a D^α_t y) = 0. \]
The stationarity condition (10) reads
\[ \int_0^1 0D^\alpha y \left( \psi(1-\alpha)0D^\alpha y - \frac{1}{\Gamma(1-\alpha)} \frac{d}{d\tau} \int_0^\tau \ln(t-\tau)y(\tau) d\tau \right) d\tau = 0, \]
and is automatically satisfied.

Note that \( C \cdot I^{1-\alpha} \in \mathcal{U} \), for all \( C \in \mathbb{R} \), but only \( I^{1-\alpha} \in \mathcal{U} \). Hence, we conclude that \((y^*, \alpha^*) = (I^{1-\alpha}, \alpha), \alpha \in [0, 1],\) are solutions to the variational problem \( I[y, \alpha] \to \min \), for \( I \) defined by (20).

**Remark 5.2.** If \( L(t, y(t), 0D^\alpha y, \alpha) = (0D^\alpha y)^2 + (\alpha - \alpha_0)^2 \), for a fixed \( \alpha_0 \in (0, 1) \), then the problem \( \int_0^1 L(t, y(t), 0D^\alpha y, \alpha) d\tau \to \min \) has a unique minimizer \((y^*, \alpha^*) = (I^{1-\alpha}, \alpha_0)\).

**Example 5.3.** Let the Lagrangian \( L \) be of the form
\[ L(t, y(t), 0D^\alpha y, \alpha) := (0D^\alpha y)^2 - c \cdot y, \quad c \in \mathbb{R}, \]
and let \( \mathcal{U} = \{ y \in \mathcal{U}_0 \mid y(0) = 0 \} \), \( A = [0, 1] \), for the variational problem
\[ \min_{(y, \alpha) \in \mathcal{U} \times A} I[y, \alpha] = \min_{(y, \alpha) \in \mathcal{U} \times A} \int_0^1 ((0D^\alpha y)^2 - c \cdot y(t)) d\tau. \]

Equations (9) and (10) become
\[ 0D^\alpha y = c, \quad \int_0^1 0D^\alpha y \cdot \frac{\partial 0D^\alpha y}{\partial \alpha} d\tau = 0. \]  
(21)

Equation (21) could be solved as follows. First, one introduces a substitution \( z(t) = 0D^\alpha y, \ t \in [0, 1] \), and solve \( 0D^\alpha z = c \):
\[ z(t) = c \cdot \frac{(1-t)^\alpha}{\Gamma(1-\alpha)}, \quad t \in [0, 1], \ \alpha \in A. \]

Therefore,
\[ 0D^\alpha y(t) = c \cdot \frac{(1-t)^\alpha}{\Gamma(1-\alpha)}, \quad t \in [0, 1], \ \alpha \in A. \]
(22)

Recall that
\[ 0I^\alpha y := \frac{1}{\Gamma(\alpha)} \int_0^1 (t-\tau)^\alpha y(\tau) d\tau, \quad t \in [0, 1], \ \alpha \in A, \]
and apply it on the both sides of (22). Using [27, theorem 2.4], i.e. \( 0I^\alpha_y(0D^\alpha y) = y(t) - \frac{c - 1}{\Gamma(1-\alpha)} I^{1-\alpha} y \big|_{t=0} \), one obtains
\[ y(t, \alpha) = \frac{c}{\Gamma(\alpha)\Gamma(1+\alpha)} \int_0^1 (t-\tau)^{\alpha-1}(1-\tau)^\alpha d\tau \]
\[ = \frac{c}{\Gamma(\alpha)\Gamma(1+\alpha)} \sum_{p=0}^{\infty} \frac{\Gamma(p-\alpha)\Gamma(1+p)}{\Gamma(-\alpha)p!\Gamma(1+p+\alpha)} I^{1-\alpha}, \quad t \in [0, 1], \ \alpha \in A. \]

This solution is unique and belongs to \( \mathcal{U} \). Since \( \alpha \mapsto y(t, \alpha) \) is differentiable, proposition 4.1 holds.

We substitute the obtained \( y(t, \alpha) \) into \( I[y, \alpha] \) which yields
\[ I[\alpha] = \int_0^1 \left( c \cdot \frac{(1-t)^\alpha}{\Gamma(1-\alpha)} \right)^2 - \frac{c^2}{\Gamma(\alpha)\Gamma(1+\alpha)} \int_0^1 (t-\tau)^{\alpha-1}(1-\tau)^\alpha d\tau \]
\[ = \int_0^1 \left( c \cdot \frac{(1-t)^\alpha}{\Gamma(1-\alpha)} \right)^2 - \frac{c^2}{\Gamma(1+\alpha)} \sum_{p=0}^{\infty} \frac{\Gamma(p-\alpha)\Gamma(1+p)}{\Gamma(-\alpha)p!\Gamma(1+p+\alpha)} I^{1-\alpha} \]
Simple numerical calculations show that $I[\alpha]$ is an increasing function and attains extremal values at the boundaries.

**Remark 5.4.** Equation (21) represents a fractional generalization of the equation of motion for a material point (with unit mass) under the action of constant force equal to $c$. Our result shows that an optimal value of Hamilton’s action is attained for $\alpha = 1$, that is for integer order dynamics. We note that different generalizations of the classical equation of motion can be found in [18], where the problem $\partial_0 D_\alpha^\alpha y = c$, $1 < \alpha \leq 2$, was analyzed.

### 5.2. Examples with Lagrangians linear in $\partial_0 D_\alpha^\alpha y$

**Example 5.5.** Let

$$L(t, y(t), \partial_0 D_\alpha^\alpha y, \alpha) := \Gamma(1 - \alpha) \partial_0 D_\alpha^\alpha y - \frac{1}{2} cy^2, \quad c > 0, c \neq 1,$$  

(23)

and consider the problem of finding stationary points for functional (1), where $U := \{y \in L_0 \mid y(0) = \frac{1}{c}\}$ and $\alpha_0 < \frac{1}{2}$. Note that $L$ satisfies the so-called primary constraint in Dirac’s classification of systems with constraints (cf [15]). In the setting of fractional derivatives such Lagrangians have been recently treated in [7] and [20].

Equations (9) and (10) become

$$\int_0^1 \left( \Gamma(1 - \alpha) \frac{\partial_0 D_\alpha^\alpha y}{\partial \alpha} + \frac{\partial \Gamma(1 - \alpha)}{\partial \alpha} \right) dt = 0.$$  

(25)

Equation (24) has a unique solution $y^* = \frac{1}{c(1 - t)^\alpha}, t \in [0, 1], \alpha \in [0, \alpha_0)$. This implies

$$I[y^*, \alpha] = \int_0^1 \left( \frac{d}{dt} \int_0^t \frac{dr}{c(1 - \tau)^\alpha(t - \tau)^\alpha} - \frac{1}{2c(1 - t)^{2\alpha}} \right) dt$$

$$= \int_0^1 \frac{dr}{c(1 - \tau)^\alpha(t - \tau)^\alpha} - \int_0^1 \frac{1}{2c(1 - t)^{2\alpha}} dt$$

$$= \frac{1}{2c} \int_0^1 \frac{1}{(1 - t)^{2\alpha}} dt.$$  

Since $\alpha_0 < 1/2$ we have that $I[y^*, \alpha]$ exists and is an increasing function with respect to $\alpha$. Hence, $I[y^*, \alpha]$ attains its minimal value at $\alpha = 0$, and it equals $1/(2c)$. We also have that the maximal value of $I[y^*, \alpha]$ is attained at $\alpha_0$.

**Example 5.6.** Let $U := \{y \in L_0 \mid y(0) = 0\}, c \neq 0$ and let $L$ be of the form

$$L(t, y(t), \partial_0 D_\alpha^\alpha y, \alpha) := c \cdot \partial_0 D_\alpha^\alpha y + f(y(t)), \quad t \in [0, 1],$$  

(26)

where the properties of $f$ are going to be specified.

In this example we are dealing with integrable functions which can take values $+\infty$ or $-\infty$ at some points. We are going to analyze stationary points of

$$I[y, \alpha] = \int_0^1 (c \cdot \partial_0 D_\alpha^\alpha y(t) + f(y(t))) dt.$$  

9
Equations (9) and (10) become
\[ t \cdot D_1^\alpha c + \frac{\partial f}{\partial y} = 0 \quad (27) \]
\[ c \cdot \int_0^1 \frac{\partial_0 D_0^\alpha y}{\partial \alpha} \, dt = 0. \quad (28) \]

Since \( t \cdot D_1^\alpha c = \frac{c}{\Gamma(1-\alpha)(1-t)^\alpha}, \ t \in [0, 1], \) we see that in order to solve (27)–(28) we have to assume that \( f \in C^1(\mathbb{R}) \), and that \( f' \) is invertible so that \( t \mapsto (f')^{-1}\left(\frac{c}{\Gamma(1-\alpha)(1-t)^\alpha}\right) \in \mathcal{U}_c \). Then equation (27) is solvable with respect to \( y \):
\[ y_c(t, \alpha) = \left(\frac{\partial f}{\partial y}\right)^{-1} \left(\frac{c}{\Gamma(1-\alpha)(1-t)^\alpha}\right), \quad t \in [0, 1]. \quad (29) \]

Since \( c \neq 0 \), (28) implies \( \int_0^1 \frac{\partial_0 D_0^\alpha y}{\partial \alpha} \, dt = 0. \) Thus,
\[ 0 = \int_0^1 \frac{\partial_0 D_0^\alpha y}{\partial \alpha} \, dt = \int_0^1 G(y, \alpha)(t) \, dt = \int_0^1 \frac{d}{dt} (f_1 \ast y(t, \alpha) \, dt = f_1 \ast y(t, \alpha)|_{t=1}, \quad (30) \]
where we have used that \( f_1 \in L^1([0, 1]) \) and that \( y \in \mathcal{U}_c \). Substitution of (29) into (30) gives
\[ (f_1 \ast y_c(t, \alpha))(t)|_{t=1} = 0 \text{ or} \]
\[ \int_0^1 \psi(1-\alpha) - \ln(1-\tau) \frac{1}{\Gamma(1-\alpha)(1-\tau)^\alpha} \, d\tau = 0. \quad (31) \]

Solving this equation is obviously difficult. Hence, we consider some special cases.

(a) \( f(y(t)) := d \cdot \frac{y(t)^2}{2}, \ t \in [0, 1], \ d \in \mathbb{R} \). Then the Lagrangian is
\[ L(t, y(t), 0D_0^\alpha y, \alpha) = c \cdot 0D_0^\alpha y(t) + d \cdot \frac{y(t)^2}{2}, \]
and
\[ y_c(t, \alpha) = -\frac{d}{c} \frac{1}{\Gamma(1-\alpha)(1-t)^\alpha}, \quad t \in [0, 1]. \]

Also, (31) becomes
\[ \int_0^1 \psi(1-\alpha) - \ln(1-\tau) \frac{1}{\Gamma(1-\alpha)(1-\tau)^\alpha} \, d\tau = 0. \]

By a simple numerical calculation one shows that this equation does not have any solution for \( \alpha \in (0, 1) \). Hence, in this case there does not exist any point \( (y, \alpha) \) which is an extremal of functional \( I[y, \alpha] \).

(b) \( f(y(t)) := \ln y(t), \ t \in [0, 1] \). Then (27) becomes
\[ \frac{c}{\Gamma(1-\alpha)(1-t)^\alpha} = \frac{1}{y}, \]
and therefore
\[ y = \frac{\Gamma(1-\alpha)}{c}(1-t)^\alpha \in AC([0, 1]). \]

In this particular case we take the set of admissible functions to be \( \mathcal{U}_c := \{ y \in \mathcal{U} \mid y(1) = 0 \} \). Using (30), equation (28) reads
\[ \int_0^1 (\psi(1-\alpha) - \ln(1-\tau)) \, d\tau = 0, \]
which, after integration, yields $\psi(\alpha - 1) = 1$. A unique solution of this equation in $(0, 1)$ is $\alpha = 0.604\ldots$.

Therefore, a unique stationary point of

$$I[y, \alpha] = \int_0^1 (c \cdot \alpha D_t^\alpha y + \ln y(t)) \, dt$$

is the point $(y, \alpha) = \left(\Gamma(0.396) (1 - t)^\alpha; 0, 604\right)$.

**Remark 5.7.** So far, we have considered variational problems defined via functionals of type (1). In fact, we have allowed fractional derivatives of functions to appear in Lagrangians. The natural generalization of such problems consists of replacing the Lebesgue integral in (1) by the Riemann–Liouville fractional integral. More precisely, for $\beta > 0$ set

$$I_\beta[y, \alpha] := \alpha I_\beta^\beta L(t, y(t), 0D_t^\alpha y, \alpha)$$

$$= \frac{1}{\Gamma(\beta)} \int_0^b (b - t)^{\beta - 1} L(t, y(t), 0D_t^\alpha y, \alpha) \, dt, \quad t \in (0, b).$$

Then the fractional variational problem consists of finding extremal values of the functional $I_\beta[y, \alpha]$.

In the above construction we have used the left Riemann–Liouville fractional integral of order $\beta$ (which, in general, differs from the order of fractional differentiation $\alpha$), evaluated at $t = b$. The choice $\beta = 1$ turns us back to the problem (1).

The study of such fractional variational problems is reduced to the case we have already considered in the following way. It suffices to redefine the Lagrangian as

$$L_1(t, y(t), 0D_t^\alpha y, \alpha, \beta) := \frac{1}{\Gamma(\beta)} (b - t)^{\beta - 1} L(t, y(t), 0D_t^\alpha y, \alpha).$$

Then we have to consider the functional

$$I_\beta[y, \alpha] = \int_0^b L_1(t, y(t), 0D_t^\alpha y, \alpha, \beta) \, dt. \quad (32)$$

In case $\beta > 1$, $L_1$ is of the same regularity as $L$, so the straightforward application of the results derived in the previous sections to the Lagrangian $L_1$ leads to the optimality conditions for the variational problem defined via functional (32). However, when $0 < \beta < 1$, continuity as well as differentiability of $L_1$ with respect to $t$ may be violated (which depends of the explicit form of $L$), and hence it may not be possible to use the theory developed so far.

### 6. Conclusion

We formulated Hamilton’s principle so that the order of the derivative in the Lagrangian is also subject to variation. The stationarity conditions are derived in (9) and (10). We introduced additional assumptions which resulted in equivalent problems, simpler for solving. Several examples are given in order to illustrate the theory presented in the paper. We concluded our work with a consideration of Hamilton’s principle defined in terms of Riemann–Liouville fractional integrals.
