Optimal Uniform Convergence Rates and Asymptotic Normality for Series Estimators Under Weak Dependence and Weak Conditions

Xiaohong Chen† and Timothy M. Christensen‡

First version January 2012; Revised August 2013, August 2014

Abstract

We show that spline and wavelet series regression estimators for weakly dependent regressors attain the optimal uniform (i.e. sup-norm) convergence rate \((n/\log n)^{-p/(2p+d)}\) of Stone (1982), where \(d\) is the number of regressors and \(p\) is the smoothness of the regression function. The optimal rate is achieved even for heavy-tailed martingale difference errors with finite \((2 + (d/p))\)th absolute moment for \(d/p < 2\). We also establish the asymptotic normality of t statistics for possibly nonlinear, irregular functionals of the conditional mean function under weak conditions. The results are proved by deriving a new exponential inequality for sums of weakly dependent random matrices, which is of independent interest.

1 Introduction

We study the nonparametric regression model

\[ Y_i = h_0(X_i) + \epsilon_i \]
\[ E[\epsilon_i | X_i] = 0 \]

(1)

where \( Y_i \in \mathbb{R} \) is a scalar response variable, \( X_i \in \mathcal{X} \subseteq \mathbb{R}^d \) is a \( d \)-dimensional regressor (predictor variable), and the conditional mean function \( h_0(x) = E[Y_i | X_i = x] \) belongs to a Hölder space of smoothness \( p > 0 \). We are interested in series least squares (LS) estimation\(^1\) of \( h_0 \) under sup-norm loss and inference on possibly nonlinear functionals of \( h_0 \) allowing for weakly dependent regressors and heavy-tailed errors \( \epsilon_i \).

For i.i.d. data, Stone (1982) shows that \((n/\log n)^{-p/(2p+d)}\) is the minimax lower bound in sup-norm risk for estimation of \( h_0 \) over a Hölder ball of smoothness \( p > 0 \). For strictly stationary beta-mixing regressors, we show that spline and wavelet series LS estimators \( \hat{h} \) of \( h_0 \) attain the optimal uniform rate of Stone (1982) under a mild unconditional moment condition \( E[|\epsilon_i|^{2+(d/p)}] < \infty \) imposed on the martingale difference errors.

More generally, we assume the error process \( \{\epsilon_i\}_{i=\infty}^{-\infty} \) is a martingale difference sequence but impose no explicit weak dependence condition on the regressor process \( \{X_i\}_{i=\infty}^{-\infty} \). Rather, weak dependence of the regressor process is formulated in terms of convergence of a certain random matrix. We verify this condition for absolutely regular (beta-mixing) sequences by deriving a new exponential inequality for sums of weakly dependent random matrices. This new inequality then leads to a sharp upper bound on the sup-norm variance term of series LS estimators with an arbitrary basis. When combined with a general upper bound on the sup-norm bias term of series LS estimators, the sharp sup-norm variance bound immediately leads to a general upper bound on the sup-norm convergence rate of series LS estimators with an arbitrary basis and weakly dependent data.

In our sup-norm bias and variance decomposition of series LS estimators, the bound on the sup-norm bias term depends on the sup norm of the empirical \( L^2 \) projection onto the linear sieve space. The sup norm of the empirical \( L^2 \) projection varies with the choice of the (linear sieve) basis. For spline

---

\(^1\)Other terms for series LS appearing in the literature include series regression and linear sieve regression, but we use series LS hereafter. The series LS estimator falls into the general class of nonparametric sieve M-estimators.

\(^2\)The error \( \epsilon_i \) is heavy-tailed in the sense that \( E[|\epsilon_i|^{2+\delta}] = \infty \) for \( \delta > d/p \) is allowed; say \( E[|\epsilon_i|^4] = \infty \) is allowed.
regression with i.i.d. data, Huang (2003b) shows that the sup norm of the empirical $L^2$ projection onto splines is bounded with probability approaching one (wp1). Using our new exponential inequality for sums of weakly dependent random matrices, his bound is easily extended to spline regression with weakly dependent regressors. In addition, we show in Theorem 5.2 that, for either i.i.d. or weakly dependent regressors, the sup norm of the empirical $L^2$ projection onto compactly supported wavelet bases is also bounded wp1 (this property is called sup-norm stability of empirical $L^2$ projection). These tight bounds lead to sharp sup-norm bias control for spline and wavelet series LS estimators. They allow us to show that spline and wavelet series LS estimators achieve the optimal sup-norm convergence rate with weakly dependent data and heavy-tailed errors (e.g., $E[\epsilon_i^4] = \infty$ is allowed).

Sup-norm (uniform) convergence rates of series LS estimators have been studied previously by Newey (1997) and de Jong (2002) for i.i.d. data and Lee and Robinson (2013) for spatially dependent data. But the uniform convergence rates obtained in these papers are slower than the optimal rate of Stone (1982). In an important paper on series LS regression with i.i.d. data, Belloni, Chernozhukov, Chetverikov, and (2014) establish the attainability of the optimal sup-norm rates of series LS estimators using spline, local polynomial partition, wavelet and other series possessing the property of sup-norm stability of the $L^2$ projection (or bounded Lebesgue constant) under the conditional moment condition $\sup_x E[|\epsilon_i|^{2+\delta} |X_i = x] < \infty$ for some $\delta > d/p$. Our Theorem 5.1 on the sup-norm stability of $L^2$ projection of the wavelet basis is used by Belloni et al. (2014) to show that the wavelet series LS estimator achieves the optimal sup-norm rate under their conditional moment requirement. Our paper contributes to the literature by showing that spline and wavelet series LS estimators attain the optimal sup-norm rate with strictly stationary beta-mixing regressors under the weaker unconditional moment requirement $E[|\epsilon_i|^{2+(d/p)}] < \infty$.

As another application of our new exponential inequality, under very weak conditions we obtain sharp $L^2$ convergence rates for series LS estimators with weakly dependent regressors. For example, under the minimal bounded conditional second moment restriction ($\sup_x E[|\epsilon_i|^2 |X_i = x] < \infty$), our $L^2$-norm rates for trigonometric polynomial, spline or wavelet series LS estimators attain Stone (1982)’s optimal $L^2$-norm rate of $n^{-p/(2p+d)}$ with strictly stationary, exponentially beta-mixing (respectively algebraically beta-mixing at rate $\gamma$) regressors with $p > 0$ (resp. $p > d/(2\gamma)$), while the power series LS

---

3See Hansen (2008), Kristensen (2009), Masry (1996), Tsybakov (2009), Cattaneo and Farrel (2013) and the references therein for attainability of the optimal uniform convergence rates with kernel, local linear regression and partitioning estimators.
estimator attains the same optimal rate with exponentially (resp. algebraically) beta-mixing regressors for \( p > d/2 \) (resp. \( p > d(2 + \gamma)/(2\gamma) \)). It is interesting to note that for a smooth conditional mean function, we obtain the optimal \( L^2 \) convergence rates for these commonly used series LS estimators with weakly dependent regressors without requiring the existence of higher-than-second unconditional moments of the error terms. Previously, Newey (1997) derived the optimal \( L^2 \) convergence rates of series LS estimator under i.i.d. data and the restriction of \( K^2/n = o(1) \) for spline and trigonometric series (and \( K^3/n = o(1) \) for power series), where \( K \) is the series number of terms. The restriction on \( K \) is relaxed to \( K(\log K)/n = o(1) \) in Huang (2003a) for splines and in Belloni et al. (2014) for wavelets, trigonometric and other series under i.i.d. data. We show that the optimal \( L^2 \) convergence rates are still attainable for splines, wavelets, trigonometric and other series under exponentially beta-mixing and \( K(\log K)^2/n = o(1) \).

We also show that feasible asymptotic inference can be performed on a possibly nonlinear functional \( f(h_0) \) using the plug-in series LS estimator \( f(\hat{h}) \). We establish the asymptotic normality of \( f(\hat{h}) \) and of the corresponding Student t statistic for weakly dependent data under mild low-level conditions. When specializing to general irregular (i.e., slower than \( \sqrt{n} \)-estimable) but sup-norm bounded linear functionals of spline or wavelet series LS estimators with i.i.d. data, we obtain the asymptotic normality of \( f(\hat{h}) \)

\[
\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{V_{1/2}K} \rightarrow_d N(0,1)
\]

under remarkably mild conditions of (1) uniform integrability \( \sup_{x \in \mathcal{X}} E[\epsilon_i^2(\{\epsilon_i > \ell(n)\}|X_i = x)] \rightarrow 0 \) for any \( \ell(n) \rightarrow \infty \) as \( n \rightarrow \infty \), and (2) \( K^{-p/d}\sqrt{n/V_K} = o(1) \), \( (K \log K)/n = o(1) \), where \( V_K \) is the sieve variance that grows with \( K \) for irregular functionals. These conditions coincide with the weakest known conditions in Huang (2003b) for the pointwise asymptotic normality of spline LS estimators, except we also allow for other irregular linear functionals of spline or wavelet LS estimators. When specializing to general irregular but sup-norm bounded nonlinear functionals of spline or wavelet series LS estimators with i.i.d. data, we obtain asymptotic normality of \( f(\hat{h}) \) (and of its t statistic) under conditions (1) and (3) \( K^{-p/d}\sqrt{n/V_K} = o(1) \), \( K^{(2+\delta)/\delta}(\log n)/n \lesssim 1 \) (and \( K^{(2+\delta)/\delta}(\log n)/n = o(1) \) for the t statistic) for \( \delta \in (0,2) \) such that \( E[|\epsilon_i|^{2+\delta}] < \infty \). These conditions are much weaker than the well-known conditions in Newey (1997) for the asymptotic normality of a nonlinear functional and its t

\footnote{Most of the literature has focused on the case of i.i.d. or strictly stationary data. See Andrews (1991) for asymptotic normality of linear functionals of series LS estimators with non-identically distributed data.}
statistic of spline LS estimator, namely \( K^{-p/d} \sqrt{n} = o(1) \), \( K^4/n = o(1) \) and \( \sup_x E[|\epsilon_i|^4 |X_i = x] < \infty \).

Moreover, under a slightly more restrictive growth condition on \( K \) but without the need to increase \( \delta \), we show that our mild sufficient conditions for the i.i.d. case extend naturally to the weakly dependent case. Our conditions for the weakly dependent case relax the higher-order-moment requirement in Chen, Liao, and Sun (2014) for sieve \( t \) inference on nonlinear functionals of linear sieve time series LS regressions.

Our paper improves upon the existing results on the asymptotic normality of \( t \) statistics of nonlinear functionals of a series LS estimator under dependent data by allowing for heavy-tailed errors \( \epsilon_i \) and relaxing the growth rates of the series term \( K \) but maintaining the bounded conditional error variance assumption. For i.i.d. data, Hansen (2014) derives pointwise asymptotic normality for linear functionals of a series LS estimator allowing for unbounded regressors, unbounded conditional error variance, but requiring \( E[|\epsilon_i|^{4+\eta}] < \infty \) for some \( \eta > 0 \). In addition to pointwise limiting distribution results, Belloni et al. (2014) also provide uniform limit theory and uniform confidence intervals for linear functionals of a series LS estimator with i.i.d. data.

Our paper, Belloni et al. (2014) and Hansen (2014) all employ tools from recent random matrix theory to derive various new results for series LS estimation. Belloni et al. (2014) are the first to apply the non-commutative Khinchin random matrix inequality for i.i.d. data. Instead, we apply an exponential inequality for sums of independent random matrices due to Tropp (2012). Our results for series LS with weakly dependent data rely crucially on our extension of Tropp’s matrix exponential inequality from i.i.d. data to weakly dependent data. See Hansen (2014) for other applications of Tropp’s inequality to series LS estimators with i.i.d. data.

Since economic and financial time series data often have infinite forth moments, the new improved rates and inference results in our paper should be very useful to the literatures on nonparametric estimation and testing of nonlinear time series models (see, e.g., Robinson (1989), Li, Hsiao, and Zinn (2003), Fan and Yao (2003), Chen (2013)). Moreover, our new exponential inequality for sums of weakly dependent random matrices should be useful in series LS estimation of spatially dependent models and in other contexts as well.\(^5\)

The rest of the paper is organized as follows. Section 2 first derives general upper bounds on the sup-norm convergence rates of series LS estimators with an arbitrary basis. It then shows that spline

\(^5\)In our ongoing work on sieve estimation of semi/nonparametric conditional moment restriction models with time series data, this new exponential inequality also enables us to establish asymptotic properties under weaker conditions.
and wavelet series LS estimators attain the optimal sup-norm rates, allowing for weakly dependent
data and heavy tailed error terms. It also presents general sharp $L^2$-norm convergence rates of series
LS estimators with an arbitrary basis under very mild conditions. Section 3 provides the asymptotic
normality of sieve t statistics for possibly nonlinear functionals of $h_0$. Section 4 provides new exponen-
tial inequalities for sums of weakly dependent random matrices, and a reinterpretation of equivalence
of the theoretical and empirical $L^2$ norms as a criterion regarding convergence of a certain random
matrix. Section 5 shows the sup-norm stability of the empirical $L^2$ projections onto compactly sup-
ported wavelet bases, which provides a tight upper bound on the sup-norm bias term for the wavelet
series LS estimator. The results in Sections 4 and 5 are of independent interest. Section 6 contains a
brief review of spline and wavelet sieve bases. Proofs and ancillary results are presented in Section 7.

**Notation:** Let $\lambda_{\min}(\cdot)$ and $\lambda_{\max}(\cdot)$ denote the smallest and largest eigenvalues, respectively, of a
matrix. The exponent -$^\dagger$ denotes the Moore-Penrose generalized inverse. $\| \cdot \|$ denotes the Euclidean
norm when applied to vectors and the matrix spectral norm (i.e., largest singular value) when applied
to matrices, and $\| \cdot \|_{\ell^p}$ denotes the $\ell^p$ norm when applied to vectors and its induced operator norm
when applied to matrices (thus $\| \cdot \| = \| \cdot \|_{\ell^2}$). If $\{a_n : n \geq 1\}$ and $\{b_n : n \geq 1\}$ are two sequences
of non-negative numbers, $a_n \preceq b_n$ means there exists a finite positive $C$ such that $a_n \leq Cb_n$ for all
$n$ sufficiently large, and $a_n \asymp b_n$ means $a_n \preceq b_n$ and $b_n \preceq a_n$. $\#S$ denotes the cardinality of a set
$S$ of finitely many elements. Given a strictly stationary process $\{X_i\}$ and $1 \leq p < \infty$, we let $L^p(X)$
denote the function space consisting of all (equivalence classes) of measurable functions $f$ for which
the $L^p(X)$ norm $\|f\|_{L^p(X)} \equiv E[|f(X_i)|^p]^{1/p}$ is finite, and we let $L^\infty(X)$ denote the space of bounded
functions under the sup norm $\| \cdot \|_{\infty}$, i.e., if $f : X \rightarrow \mathbb{R}$ then $\|f\|_{\infty} \equiv \sup_{x \in X} |f(x)|$.

## 2 Uniform Convergence Rates

In this section we present some general results on uniform convergence properties of nonparametric
series LS estimators with weakly dependent data.

### 2.1 Estimator and basic assumptions

In nonparametric series LS estimation, the conditional mean function $h_0$ is estimated by least squares
regression of $Y_1, \ldots, Y_n$ on a vector of sieve basis functions evaluated at $X_1, \ldots, X_n$. The standard
series LS estimator of the conditional mean function $h_0$ is

$$\hat{h}(x) = b^K(x)'(B'B)^{-1}B'Y \tag{2}$$

where $b_{K1}, \ldots, b_{KK}$ are a collection of $K$ sieve basis functions and

$$b^K(x) = (b_{K1}(x), \ldots, b_{KK}(x))' \tag{3}$$

$$B = (b^K(X_1), \ldots, b^K(X_n))' \tag{4}$$

$$Y = (Y_1, \ldots, Y_n)' \tag{5}$$

Choosing a particular class of sieve basis function and the dimension $K$ are analogous to choosing the type of kernel and bandwidth, respectively, in kernel regression techniques. The basis functions are chosen such that their closed linear span $B_K = \text{clsp}\{b_{K1}, \ldots, b_{KK}\}$ can well approximate the space of functions in which $h_0$ is assumed to belong.

When the data $\{(X_i, Y_i)\}_{i=1}^n$ are a random sample it is often reasonable to assume that $X$ is supported on a compact set $\mathcal{X} \subset \mathbb{R}^d$. However, in a time-series setting it may be necessary to allow the support $\mathcal{X}$ of $X$ to be infinite, as in the example of nonparametric autoregressive regression with a student $t$ distributed error term. See, e.g., Fan and Yao (2003) and Chen (2013) for additional examples and references.

To allow for possibly unbounded support $\mathcal{X}$ of $X_i$ we modify the usual series LS estimator and notion of convergence. First, we weight the basis functions by a sequence of non-negative weighting functions $w_n : \mathcal{X} \rightarrow \{0, 1\}$ given by

$$w_n(x) = \begin{cases} 1 & \text{if } x \in \mathcal{D}_n \\ 0 & \text{otherwise} \end{cases} \tag{6}$$

where $\mathcal{D}_n \subseteq \mathcal{X}$ is compact, convex, and has nonempty interior, and $\mathcal{D}_n \subseteq \mathcal{D}_{n+1}$ for all $n$. The resulting series LS estimator is then

$$\hat{h}_w(x) = b^K_w(x)'(B'_wB_w)^{-1}B'_wY \tag{7}$$
where $b_{K1}, \ldots, b_{KK}$ are a collection of $K$ sieve basis functions and

$$b^K_w(x) = (b_{K1}(x)w_n(x), \ldots, b_{KK}(x)w_n(x))'$$  \hspace{1cm} (8)

$$B_w = (b^K_w(X_1), \ldots, b^K_w(X_n))'.$$  \hspace{1cm} (9)

Second, we consider convergence in the (sequence of) weighted sup norm(s) $\| \cdot \|_{\infty,w}$ given by

$$\|f\|_{\infty,w} = \sup_x |f(x)w_n(x)| = \sup_{x \in D_n} |f(x)|$$  \hspace{1cm} (10)

This modification is made because simple functions, such as polynomials of $x$, have infinite sup norm when $X_i$ has unbounded support, but will have finite weighted sup norm.

**Remark 2.1** When $\mathcal{X}$ is compact we may simply set $w_n(x) = 1$ for all $x \in \mathcal{X}$ and all $n$. With such a choice of weighting, the series LS estimator with weighted basis trivially coincides with the series LS estimator in (2) with unweighted basis, and $\| \cdot \|_{\infty,w} = \| \cdot \|_{\infty}$.

When $\mathcal{X}$ is unbounded there are several possible choices for $D_n$. For instance, we may take $D_n = D$ for all $n$, where $D \subseteq \mathcal{X}$ is a fixed compact convex set with nonempty interior. This approach is not without precedent in the nonparametric analysis of nonlinear time series models. For example, Huang and Shen (2004) use a similar approach to trim extreme observations in nonparametric functional coefficient regression models, following Tjøstheim and Auestad (1994). More generally, we can consider an expanding sequence of compact nonempty sets $D_n \subset \mathcal{X}$ with $D_n \subseteq D_{n+1}$ for all $n$ and set $w_n(x) = \{x \in D_n\}$ for all $n$. For example, if $\mathcal{X} = \mathbb{R}^d$ we could take $D_n = \{x \in \mathbb{R}^d : \|x\|_p \leq r_n\}$ where $0 < r_n \leq r_{n+1} < \infty$ for all $n$. This approach is similar to excluding functions far from the support of the data when performing series LS estimation with a compactly-supported wavelet basis for $L^2(\mathbb{R})$ or $L^2(\mathbb{R}^d)$. We defer estimation with smooth weighting functions of the form $w_n(x) = (1 + \|x\|^2)^{-\omega}$ or $w_n(x) = \exp(-\|x\|^\omega)$ to future research.

We first introduce some mild regularity conditions that are satisfied by typical regression models and most linear sieve bases.

**Assumption 1** (i) $\{X_i\}_{i=-\infty}^\infty$ is strictly stationary, (ii) $\mathcal{X} \subseteq \mathbb{R}^d$ is convex and has nonempty interior.
Assumption 2 (i) \( \{\epsilon_i, F_{i-1}\}_{i=1}^n \) with \( F_{i-1} = \sigma(X_i, \epsilon_{i-1}, X_{i-1}, \ldots) \) is a strictly stationary martingale difference sequence, (ii) \( E[\epsilon_i^2 | F_{i-1}] \) is uniformly bounded for all \( i \geq 1 \), almost surely, (iii) \( E[|\epsilon_i|^{2+\delta}] < \infty \) for some \( \delta > 0 \).

Let \( N(D_n, \epsilon) \) denote the internal \( \epsilon \)-covering number of \( D_n \) with respect to the Euclidean norm (i.e. the minimum number of points \( x_1, \ldots, x_m \in D_n \) such that the collection of \( \epsilon \)-balls centered at each of \( x_1, \ldots, x_m \) cover \( D_n \)).

Assumption 3 (i) \( D_n \) is compact, convex, has nonempty interior, and \( D_n \subseteq D_{n+1} \) for all \( n \), (ii) there exists \( \nu_1, \nu_2 > 0 \) such that \( N(D_n, \epsilon) \lesssim n^{\nu_1} \epsilon^{-\nu_2} \).

Define \( \zeta_{K,n} \equiv \sup_x \| b^K_w (x) \| \) and \( \lambda_{K,n} \equiv \left[ \lambda_{\min}(E[b^K_w (X_i)b^K_w (X_i)]) \right]^{-1/2} \).

Assumption 4 (i) there exist \( \omega_1, \omega_2 \geq 0 \) s.t. \( \sup_{x \in D_n} \| \nabla b^K_w (x) \| \lesssim n^{\omega_1} K^{\omega_2} \), (ii) there exist \( \varpi_1 \geq 0, \varpi_2 > 0 \) s.t. \( \zeta_{K,n} \lesssim n^{\varpi_1} K^{\varpi_2} \), (iii) \( \lambda_{\min}(E[b^K_w (X_i)b^K_w (X_i)]) > 0 \) for each \( K \) and \( n \).

Assumptions 1 and 2 trivially nest i.i.d. sequences, but also allow the regressors to exhibit quite general weak dependence. Note that Assumption 2(ii) reduces to \( \sup_x E[\epsilon_i^2 | X_i = x] < \infty \) in the i.i.d. case. Suitable choice of \( \delta \) in Assumption 2(iii) for attainability of the optimal uniform rate will be explained subsequently. Strict stationarity of \( \{\epsilon_i\} \) in Assumption 2 may be dropped provided the sequence \( \{|\epsilon_i|^{2+\delta}\} \) is uniformly integrable. However, strict stationarity is used to present simple sufficient conditions for the asymptotic normality of functionals of \( \hat{h} \) in Section 3.

Assumption 3 is trivially satisfied when \( \mathcal{X} \) is compact and \( D_n = \mathcal{X} \) for all \( n \). More generally, when \( \mathcal{X} \) is noncompact and \( D_n \) is an expanding sequence of compact subsets of \( \mathcal{X} \) as described above, Assumption 3(ii) is satisfied provided each \( D_n \) is contained in an Euclidean ball of radius \( r_n \lesssim n^\nu \) for some \( \nu > 0 \).

Assumption 4 is a mild regularity condition on the sieve basis functions. When \( \mathcal{X} \) is compact and rectangular this assumption is satisfied by all the widely used series (or linear sieve bases) with \( \lambda_{K,n} \lesssim 1 \), and \( \zeta_{K,n} \lesssim \sqrt{K} \) for tensor-products of univariate polynomial spline, trigonometric polynomial or wavelet bases, and \( \zeta_{K,n} \lesssim K \) for tensor-products of power series or orthogonal polynomial bases (see, 6By translational invariance we may assume that \( D_n \) is centered at the origin. Then \( D_n \subseteq \mathcal{R}_n = [-r_n, r_n]^d \). We can cover \( \mathcal{R}_n \) with \( (r_n/\epsilon)^d \) \( \epsilon \)-balls of radius \( \epsilon \), each of which is contained in an Euclidean ball of radius \( \epsilon \sqrt{d} \). Therefore, \( N(D_n, \epsilon) \leq (\sqrt{d} r_n)^d \epsilon^{-d} \lesssim n^d \epsilon^{-d} \).

9
Let $\widetilde{b}_w^K(x)$ denote the orthonormalized vector of basis functions, namely
\[
\widetilde{b}_w^K(x) = E[b_w^K(X_i)b_w^K(X_i)]^{-1/2}b_w^K(x),
\]
and let $\widetilde{B}_w = (\widetilde{b}_w^K(X_1), \ldots, \widetilde{b}_w^K(X_n))'$.

**Assumption 5** Either: (a) $\{X_i\}_{i=1}^n$ is i.i.d. and $\zeta_{K,n} \lambda_{K,n} \sqrt{(\log K)/n} = o(1)$, or (b) $\|\widetilde{B}_w'\widetilde{B}_w/n - I_K\| = o_p(1)$.

Assumption 5 is a mild but powerful condition that ensures the empirical and theoretical $L^2$ norms are equivalent over the linear sieve space $wpal$ (see Section 4 for details). In fact, to establish many of our results below with weakly dependent data, nothing further about the weak dependence properties of the regressor process $\{X_i\}_{i=1}^n$ needs to be assumed beyond convergence of $\|\widetilde{B}_w'\widetilde{B}_w/n - I_K\|$ to zero.

In the i.i.d. case, the following Lemma shows that part (a) of Assumption 5 automatically implies $\|\widetilde{B}_w'\widetilde{B}_w/n - I_K\| = o_p(1)$.

**Lemma 2.1** Under Assumption 4(iii), if $\{X_i\}_{i=1}^n$ is i.i.d. then
\[
\|\widetilde{B}_w'\widetilde{B}_w/n - I_K\| = O_p \left( \zeta_{K,n} \lambda_{K,n} \sqrt{(\log K)/n} \right) = o_p(1)
\]
provided $\zeta_{K,n} \lambda_{K,n} \sqrt{(\log K)/n} = o(1)$.

**Remark 2.2** Consider the compact support case in which $\mathcal{X} = [0,1]^d$ and $w_n(x) = 1$ for all $x \in \mathcal{X}$ and all $n$ (so that $b_{K,n}(x)w_n(x) = b_K(x)$ for all $n$ and $K$) and suppose the density of $X_i$ is uniformly bounded away from zero and infinity over $\mathcal{X}$. In this setting, we have $\lambda_{K,n} \lesssim 1$. If $\{X_i\}_{i=1}^n$ is i.i.d., then Assumption 5 is satisfied with $\sqrt{(K \log K)/n} = o(1)$ for spline, trigonometric polynomial or wavelet bases, and with $K \sqrt{(\log K)/n} = o(1)$ for (tensor-product) power series.

When the regressors are $\beta$-mixing (see Section 4 for definition), the following Lemma shows that Assumption 5(b) is still easily satisfied.
Lemma 2.2 Under Assumption 7(iii), if \( \{X_i\}_{i=-\infty}^{\infty} \) is strictly stationary and \( \beta \)-mixing with mixing coefficients such that one can choose an integers \( q = q(n) \leq n/2 \) with \( \beta(q)/q = o(1) \), then

\[
\left\| \frac{\tilde{B}_w B_w}{n} - I_K \right\| = O_p \left( \zeta_{K,n} \lambda_{K,n} \sqrt{(q \log K)/n} \right) = o_p(1)
\]

provided \( \zeta_{K,n} \lambda_{K,n} \sqrt{(q \log K)/n} = o(1) \).

Remark 2.3 Consider the compact support case from Remark 2.2, with \( \{X_i\}_{i=-\infty}^{\infty} \) strictly stationary and \( \beta \)-mixing.

(i) Exponential \( \beta \)-mixing: Assumption 5(b) is satisfied with \( \sqrt{K \log n} \log(n^{2/n}) = o(1) \) for (tensor-product) spline, trigonometric polynomial or wavelet bases, and with \( K \sqrt{\log n} \log(n^{2/n}) = o(1) \) for (tensor-product) power series.

(ii) Algebraic \( \beta \)-mixing at rate \( \gamma \): Assumption 5(b) is satisfied with \( \sqrt{K \log K} \log(n^{2/n}) = o(1) \) for (tensor-product) spline, trigonometric polynomial or wavelet bases, and with \( K \sqrt{\log K} \log(n^{2/n}) = o(1) \) for (tensor-product) power series.

2.2 A general upper bound on uniform convergence rates

Let \( B_{K,w} = \text{clsp}\{b_{K1} w_n, \ldots, b_{K} w_n\} \) be a general weighted linear sieve space. Let \( \tilde{h} \) denote the projection of \( h_0 \) onto \( B_{K,w} \) under the empirical measure, that is,

\[
\tilde{h}(x) = b^K_0(x)'(B'w B_w)^{-1}B'_w H_0 = b^K_0(x)'(\tilde{B}'w B_w)^{-1}\tilde{B}'w H_0
\]

where \( H_0 = (h_0(X_1), \ldots, h_0(X_n))' \). The sup-norm distance \( \|\hat{h} - h_0\|_{\infty,w} \) may be trivially bounded using

\[
\|\hat{h} - h_0\|_{\infty,w} \leq \|h_0 - \tilde{h}\|_{\infty,w} + \|\tilde{h} - \hat{h}\|_{\infty,w} =: \text{bias term} + \text{variance term}.
\]

Sharp bound on the sup-norm variance term. The following result establishes a sharp uniform convergence rate of the variance term for an arbitrary linear sieve space. Convergence is established
in sup norm rather than the weighted sup norm \( \| \cdot \|_{\infty,w} \) because both \( \tilde{h} \) and \( \hat{h} \) have support \( \mathcal{D}_n \). Therefore, \( \| \hat{h} - \tilde{h} \|_{\infty} = \sup_{x \in \mathcal{D}_n} | \hat{h}(x) - \tilde{h}(x) | = \| \hat{h} - \tilde{h} \|_{\infty,w} \).

Lemma 2.3 Let Assumptions 7(i)(ii), 8(i)(ii)(iii), 9 and 10 hold. Then

\[
\| \hat{h} - \tilde{h} \|_{\infty} = O_p \left( \zeta_{K,n} \lambda_{K,n} \sqrt{\log(n)}/n \right) = o_p(1)
\]
as \( n, K \to \infty \) provided the following are satisfied:

(i) \( \left( \zeta_{K,n} \lambda_{K,n} \right)^{2+\delta/\delta} \lesssim \sqrt{\log(n)} \);

(ii) either: (a) \( \{(X_i, Y_i)\}_{i=1}^n \) are i.i.d., or (b) \( \sqrt{\frac{\log(n)}{n}} \times \| (\hat{B}_w \hat{B}_w \hat{B}_w) - I_K \| = O_p(1) \).

Remark 2.4 Weak dependence of the regressor process \( \{X_i\} \) is implicitly captured by the speed of convergence of \( \| (\hat{B}_w \hat{B}_w \hat{B}_w) - I_K \| \). If \( \{X_i\} \) is exponentially \( \beta \)-mixing (respectively algebraically \( \beta \)-mixing at rate \( \gamma \)), condition (ii)(b) in Lemma 2.3 is satisfied provided \( \zeta_{K,n} \lambda_{K,n} \sqrt{K \log(n)}/n = O(1) \) (respectively \( \zeta_{K,n} \lambda_{K,n} \sqrt{K \log(n)}/n = O(1) \)); see Lemma 2.2.

General bound on the sup-norm bias term. With our sharp bound on the variance term \( \| \hat{h} - \tilde{h} \|_{\infty,w} \) in hand it remains to provide a calculation for the bias term \( \| h_0 - \tilde{h} \|_{\infty,w} \). Let \( P_{K,w,n} \) be the (empirical) projection operator onto \( B_{K,w} \equiv clsp\{b_{K1}w_n, \ldots, b_{KK}w_n\} \), namely

\[
P_{K,w,n} h(x) = b_w^K(x)' \left( \frac{B_w'B_w}{n} \right)^{-1} \frac{1}{n} \sum_{i=1}^n b_w^K(X_i) h(X_i) = \tilde{h}_w^K(x)' (\hat{B}_w B_w) \tilde{B}_w H
\]

where \( H = (h(X_1), \ldots, h(X_n))' \). \( P_{K,w,n} \) is a well defined operator: if \( L_{w,n}^2(X) \) denotes the space of functions with norm \( \| \cdot \|_{w,n} \) where \( \| f \|_{w,n}^2 = \frac{1}{n} \sum_{i=1}^n f(X_i)^2 w_n(X_i) \), then \( P_{K,w,n} : L_{w,n}^2(X) \to L_{w,n}^2(X) \) is an orthogonal projection onto \( B_{K,w} \) whenever \( B_w'B_w \) is invertible (which it is wpa1 under Assumptions 4(iii) and 5).

One way to control the bias term \( \| h_0 - \tilde{h} \|_{\infty,w} \) is to bound \( P_{K,w,n} \) in sup norm. Note that \( \tilde{h} = P_{K,w,n} h_0 \). Let \( L_{w,n}^\infty(X) \) denote the space of functions for which sup \( | f(x) w_n(x) | < \infty \) and let

\[
\| P_{K,w,n} \|_{\infty,w} = \sup_{h \in L_{w,n}^\infty(X) : \| h \|_{\infty,w} \neq 0} \frac{\| P_{K,w,n} h \|_{\infty,w}}{\| h \|_{\infty,w}}
\]
denote the (weighted sup) operator norm of \( P_{K,w,n} \). The following crude bound on \( \| P_{K,w,n} \|_\infty \) is valid for general linear sieve bases and weakly dependent regressors.
Remark 2.5 Let Assumptions 2(iii) and 2 hold. Then: \( \|P_{K,w,n}\|_\infty \leq \sqrt{2} \zeta_{K,n} \lambda_{K,n} \) wpa1.

More refined bounds on \( \|P_{K,w,n}\|_\infty \) may be derived for particular linear sieves with local properties, such as splines and wavelets stated below. These more refined bounds, together with the following Lemma, lead to the optimal uniform convergence rates of series LS estimators with the particular linear sieves.

Lemma 2.4 Let the assumptions and conditions of Lemma 2.3 hold. Then:

1. \( \|\hat{h} - h_0\|_\infty \leq O_p \left( \zeta_{K,n} \lambda_{K,n} \sqrt{\log n}/n \right) + (1 + \|P_{K,w,n}\|_\infty, w) \inf_{h \in B_{K,w}} \|h_0 - h\|_\infty, w. \)

2. Further, if the linear sieve satisfies \( \zeta_{K,n} \lambda_{K,n} \lesssim \sqrt{K} \) and \( \|P_{K,w,n}\|_\infty, w = O_p(1) \), then

\[ \|\hat{h} - h_0\|_\infty \leq O_p \left( \sqrt{(K \log n)/n} + \inf_{h \in B_{K,w}} \|h_0 - h\|_\infty, w \right). \]

2.3 Attainability of optimal uniform convergence rates

We now turn to attainability of the optimal uniform rate of Stone (1982) by specific series LS estimators. To fix ideas, in what follows we take \( D_n = D = [0,1]^d \subseteq X \) for all \( n \), whence \( \|f\|_{\infty, w} = \sup_{x \in D} |f(x)| \). Let \( \Lambda^p([0,1]^d) \) denote a Hölder space of smoothness \( p \) on the domain \( [0,1]^d \) (see, e.g. Chen (2007) for definition). Let \( \text{BSpl}(K,[0,1]^d,\gamma) \) denote a B-spline sieve of degree \( \gamma \) and dimension \( K \) on the domain \( [0,1]^d \), and let \( \text{Wav}(K,[0,1]^d,\gamma) \) denote a Wavelet sieve basis of regularity \( \gamma \) and dimension \( K \) on the domain \( [0,1]^d \) (see Section 6 for details on construction of these sieve bases). Because our bases have been constructed to have support \( [0,1]^d \) we trivially have \( b_{Kk}(x) = b_{Kk}(x)w_n(x) \) for all \( k = 1, \ldots, K \) and all \( n \) and \( K \). Recall \( B_K \equiv \text{clsp}\{b_{K1}, \ldots, b_{KK}\} \) is the linear sieve space.

The following assumptions on the conditional mean function and the sieve basis functions are sufficient for attaining the optimal uniform convergence rate.

Assumption 1 (continued) (iii) \( D_n = D = [0,1]^d \subseteq X \) for all \( n \), (iv) the unconditional density of \( X_i \) is uniformly bounded away from zero and infinity on \( D \).

Assumption 6 The restriction of \( h_0 \) to \([0,1]^d \) belongs to \( \Lambda^p([0,1]^d) \) for some \( p > 0 \).

Assumption 7 The sieve \( B_K \) is \( \text{BSpl}(K,[0,1]^d,\gamma) \) or \( \text{Wav}(K,[0,1]^d,\gamma) \) with \( \gamma > \max\{p,1\} \).
Assumptions 1 and 6 are standard regularity conditions used in derivation of optimal uniform convergence rates (Stone 1982; Tsybakov 2009). Assumption (iii) implies Assumption 3. Assumptions 1 and 7 imply Assumption 4 with $\zeta_{K,n} \lesssim \sqrt{K}$ and $\lambda_{K,n} \lesssim 1$.

Let $h^*_0, K \in B_K$ solve $\inf_{h \in B_K} \|h_0 - h\|_{\infty,w}$. Assumptions 1, 6 and 7 imply that $\|h_0 - h^*_0, K\|_{\infty,w} \lesssim K^{-p/d}$ (see, e.g. DeVore and Lorentz (1993), Huang (1998), Chen (2007)). Previously Huang (2003b) showed that $\|P_{K,w,n}\|_{\infty,w} \lesssim 1 w^{pa_1}$ for spline bases with i.i.d. data. In the proof of Theorem 2.1 we extend his result to allow for weakly dependent regressors. In addition, Theorem 5.2 in Section 5 shows that $\|P_{K,w,n}\|_{\infty,w} \lesssim 1 w^{pa_1}$ for wavelet bases with i.i.d. or weakly dependent regressors.

**Theorem 2.1** Let Assumptions 1, 2(i)(ii)(iii) (with $\delta \geq d/p$), 6 and 7 hold. If $K \asymp (n/\log n)^{d/(2p+d)}$, then

$$\|\hat{h} - h_0\|_{\infty,w} = O_p((n/\log n)^{-p/(2p+d)})$$

provided that either (a), (b), or (c) is satisfied:

(a) $\{(X_i,Y_i)\}_{i=1}^n$ is i.i.d.;

(b) $\{X_i\}_{i=1}^n$ is exponentially $\beta$-mixing and $d < 2p$;

(c) $\{X_i\}_{i=1}^n$ is algebraically $\beta$-mixing at rate $\gamma$ and $(2 + \gamma)d < 2\gamma p$.

Theorem 2.1 states that the optimal uniform convergence rates of Stone (1982) are achieved by spline and wavelet series LS estimators with i.i.d. data whenever $\delta \geq d/p$. If the regressors are exponentially $\beta$-mixing the optimal rate of convergence is achieved with $\delta \geq d/p$ and $d < 2p$. The restrictions $\delta \geq d/p$ and $(2 + \gamma)d < 2\gamma p$ for algebraically $\beta$-mixing (at a rate $\gamma$) reduces naturally towards the exponentially $\beta$-mixing restrictions as the dependence becomes weaker (i.e. $\gamma$ becomes larger). In all cases, for a fixed dimension $d \geq 1$, a smoother function (i.e. bigger $p$) means a lower value of $\delta$, and hence fatter-tailed error terms $\epsilon_i$, are permitted while still obtaining the optimal uniform convergence rate. In particular this is achieved with $\delta = d/p < 2$.

**Discussion of closely related results.** Under Assumption 1 with i.i.d. data and compact $\mathcal{X}$, we can set the weight to be $w_n = 1$ for all $n$. Let $P_K$ denote the $L^2(\mathcal{X})$ orthogonal projection operator onto $B_K$, given by

$$P_K h(x) = b^K(x)' (E[b^K(X_i)b^K(X_i)'])^{-1} E[b^K(X_i)h(X_i)]$$ (16)
for any \( h \in L^2(\mathcal{X}) \), and define its \( L^\infty \) operator norm:

\[
\|P_K\|_\infty := \sup_{h \in L^\infty(\mathcal{X}):\|h\|_\infty \neq 0} \frac{\|P_K h\|_\infty}{\|h\|_\infty}.
\]

(17)

Under i.i.d. data, Assumptions 1, 2(i)(ii) (i.e., \( E[\epsilon_i | X_i] = 0 \), \( \sup_x E[|\epsilon_i|^2 | X_i = x] < \infty \)), and the conditions \( \lambda_{K,n} \lesssim 1 \), \( \zeta_{K,n}^2 K/n = o(1) \), and \( \|h_0 - h_{0,K}^*\|_\infty \lesssim K^{-p/d} \) on the series basis, Newey (1997) derived the following sup-norm convergence rates for series LS estimators with an arbitrary basis:

\[
\|\hat{h} - h_0\|_\infty \leq O_p\left( \zeta_{K,n} \sqrt{K/n} + \|P_K h_0 - h_{0,K}^*\|_\infty K^{-p/d} \right).
\]

(18)

By Remark 2.5, under the same set of mild conditions imposed in Newey (1997) (except allowing for weakly dependent regressors), the bound (18) can be slightly improved to

\[
\|\hat{h} - h_0\|_\infty \leq O_p\left( \zeta_{K,n} \sqrt{K/n} + \|P_{K,w,n} h_0 - h_{0,K}^*\|_\infty, K^{-p/d} \right).
\]

(19)

It is clear that the general bounds in (18) and (19) with an arbitrary basis are not optimal, but they are derived under the minimal moment restriction of Assumption 2(ii) without the existence of higher-than-second moments (i.e., \( \delta = 0 \) in Assumption 2(iii)).

Under the extra moment condition \( \sup_x E[|\epsilon_i|^4 | X_i = x] < \infty \), de Jong (2002) obtained the following general bound on sup-norm rates for series LS estimators with an arbitrary basis:

\[
\|\hat{h} - h_0\|_\infty \leq O_p\left( \zeta_{K,n} \sqrt{(\log n)/n} + K^{-p/d} + \|P_K h_0 - h_{0,K}^*\|_\infty \right).
\]

(20)

de Jong (2002) did not provide sharp bounds for \( \|P_K h_0 - h_{0,K}^*\|_\infty \) for any particular basis, and was therefore unable to attain the optimal convergence rate \( \|\hat{h} - h_0\|_\infty = O_p((n/\log n)^{-p/(2p+d)}) \) of Stone (1982). Note that

\[
\|P_K h_0 - h_{0,K}^*\|_\infty = \|P_K(h_0 - h_{0,K}^*)\|_\infty \leq \|P_K\|_\infty \|h_0 - h_{0,K}^*\|_\infty \lesssim \|P_K\|_\infty K^{-p/d}.
\]

(21)

Given the newly derived sharp bounds of \( \|P_K\|_\infty \lesssim 1 \) in Huang (2003b) for splines, in Belloni et al. (2014) for the local polynomial partition series, and in our paper (Theorem 5.1) for wavelets, one could now apply de Jong (2002)'s result (20) to conclude the attainability of the optimal sup-norm
rate by spline, local polynomial partition and wavelet series LS estimators for i.i.d. data. However, de Jong (2002)'s result (20) is proved under the strong bounded conditional fourth moment condition of \( \sup_x E[|\epsilon_i|^4 | X_i = x] < \infty \) and the side condition \( \zeta_{K,n}^2 K/n = o(1) \).

Recently, Cattaneo and Farrell (2013) proved that a local polynomial partitioning regression estimator can attain the optimal sup-norm rate under i.i.d. data and the conditional moment condition \( \sup_x E[|\epsilon_i|^{2+\delta} | X_i = x] < \infty \) for some \( \delta \geq \max(1, d/p) \). Belloni et al. (2014) show that spline, local polynomial partition and wavelet LS estimators attain the optimal sup-norm rate under i.i.d. data and the conditional moment condition \( \sup_x E[|\epsilon_i|^{2+\delta} | X_i = x] < \infty \) for some \( \delta > \max(1, d/p) \).

By contrast, we require a weaker unconditional moment condition \( E[|\epsilon_i|^{2+\delta}] < \infty \) for spline and wavelet LS estimators to attain the optimal uniform convergence rate, allowing for both i.i.d. data and weakly dependent regressors. It remains an open question whether one could obtain the optimal sup-norm convergence rate without imposing a finite higher-than-second unconditional moment of the error term, however.

### 2.4 A general sharp bound on \( L^2 \) convergence rates

In this subsection, we present a simple but sharp upper bound on the \( L^2 \) (or root mean square) convergence rates of series LS estimators with an arbitrary basis and weakly dependent regressors.

Recall that \( B_{K,w} = \text{clsp}\{b_{K1} w_n, \ldots, b_{KK} w_n\} \) is a general weighted linear sieve space and \( \tilde{h} = P_{K,w,n} h_0 \) is defined in (12). Let \( h_{0,K} \) be the \( L^2(X) \) orthogonal projection of the conditional mean function \( h_0 \) onto \( B_{K,w} \).

**Lemma 2.5** Let Assumptions [1(i), 2(ii), 4(iii) and 5 hold. Then:

\[
\|\hat{h} - \tilde{h}\|_{L^2(X)} = O_p\left(\sqrt{K/n}\right) \quad \text{and} \quad \|\tilde{h} - h_0\|_{L^2(X)} = O_p\left(\|h_0 - h_{0,K}\|_{L^2(X)}\right).
\]

Lemmas 2.5, 2.1 and 2.2 immediately imply the following result.

---

7Our result on sup-norm stability of wavelet basis is used by Belloni et al. (2014) for the optimal sup-norm rate of the wavelet LS estimator.

8Our proof strategy for the i.i.d. data case is similar to that in a draft note by Chen and Huang (2003), who applied Huang (2003b)'s sup-norm stability of spline basis to obtain the optimal sup-norm rate for spline series LS estimator under the condition \( E[|\epsilon_i|^{2+\delta}] < \infty \) for some \( \delta > d/p \). The authors carelessly set \( \delta = 2 \), but did not like the strong condition \( E[|\epsilon_i|^4] < \infty \) and hence did not finish the paper. The note was circulated among some colleagues and former students of the authors, and is available upon request.
Remark 2.6 Let Assumptions (i), (ii) and $\lambda_{K,n} \lesssim 1$ hold. Then: (1)

$$\|\hat{h} - h_0\|_{L^2(X)} = O_p\left(\sqrt{K/n + \|h_0 - h_{0,K}\|_{L^2(X)}}\right), \tag{22}$$

provided that either (1.a), (1.b) or (1.c) is satisfied:

(1.a) $\{X_i\}_{i=1}^n$ is i.i.d., and $\zeta_{K,n}\sqrt{(\log K)/n} = o(1)$;

(1.b) $\{X_i\}_{i=1}^n$ is exponentially $\beta$-mixing, and $\zeta_{K,n}\sqrt{(\log n)^2/n} = o(1)$;

(1.c) $\{X_i\}_{i=1}^n$ is algebraically $\beta$-mixing at rate $\gamma$, and $\zeta_{K,n}\sqrt{(\log K)/n^{\gamma/(1+\gamma)}} = o(1)$.

(2) Further, if Assumptions (i) and (iv) hold and $K \asymp (n/\log n)^{d/(2p+d)}$, then

$$\|\hat{h} - h_0\|_{L^2(X)} = O_p(n^{-p/(2p+d)})$$

provided that either (2.a) or (2.b) is satisfied:

(2.a) $\{X_i\}_{i=1}^n$ is i.i.d. or exponentially $\beta$-mixing: with $p > 0$ for trigonometric polynomial, spline or wavelet series, and $p > d/2$ for power series;

(2.b) $\{X_i\}_{i=1}^n$ is algebraically $\beta$-mixing at rate $\gamma$: with $p > d/(2\gamma)$ for trigonometric polynomial, spline or wavelet series; and $p > d(2 + \gamma)/(2\gamma)$ for power series.

With i.i.d. data under the condition $\lambda_{K,n} \lesssim 1$, Newey (1997) derived the same sharp $L^2$ rate in (22) for series LS estimators under the restriction $\zeta_{K,n}K/n = o(1)$. Huang (2003a) showed that spline LS estimator has the same $L^2$ rate under the much weaker condition $K(\log K)/n = o(1)$. Both Belloni et al. (2014) and our Remark 2.6 part (1.a) extend Huang (2003a)'s weakened condition to other bases satisfying $\zeta_{K,n} \lesssim \sqrt{K}$ (such as trigonometric polynomial and wavelet) for series LS regression with i.i.d. data. In addition, Remark 2.6 part (1.b) shows that the mild condition $K(\log K)^2/n = o(1)$ suffices for trigonometric polynomial, wavelet, spline and other bases satisfying $\zeta_{K,n} \lesssim \sqrt{K}$ for exponentially $\beta$-mixing regressors.

With weakly-dependent data, Chen and Shen (1998) derived $L^2$ rates for LS regression using various linear or nonlinear sieves with beta-mixing sequence under higher-than-second moment restriction (see Proposition 5.1 in Chen and Shen (1998)). Huang and Yang (2004) and others derived the optimal $L^2$ rate for spline LS regression with strongly mixing sequence assuming a uniformly bounded
higher-than-second conditional moment. Thanks to our Lemma 2.2, we are able to show that series LS estimators with arbitrary bases attain the optimal $L^2$ convergence rate with beta-mixing regressors under a uniformly bounded second conditional moment condition on the residuals. Our result should be very useful to nonparametric series regression for financial time series data with heavy-tailed errors.

3 Inference on possibly nonlinear functionals

We now study inference on possibly nonlinear functionals $f: L^2(X) \cap L^\infty(X) \to \mathbb{R}$ of the regression function $h_0$. Examples of functionals include, but are not limited to, the pointwise evaluation functional, the partial mean functional, and consumer surplus (see, e.g., Newey (1997) for examples). The functional $f(h_0)$ may be estimated using the plug-in series LS estimator $f(\hat{h})$, for which we now establish feasible limit theory.

As with Newey (1997) and Chen et al. (2014), our results allow researchers to perform inference on nonlinear functionals $f$ of $h_0$ without needing to know whether or not $f(h_0)$ is regular (i.e., $\sqrt{n}$-estimable). However, there is already a large literature on the $\sqrt{n}$-asymptotic normality and the consistent variance estimation for series estimators of regular functionals of conditional mean functions with weakly dependent data (see, e.g., Chen and Shen (1998), Chen (2007), Li and Racine (2006)). To save space and to illustrate the usefulness of our new sup-norm convergence rate results, we focus on asymptotic normality of $f(\hat{h})$ and the corresponding sieve t statistic when the functional is irregular (i.e., slower than $\sqrt{n}$-estimable) in this section.

We borrow some notation and definitions from Chen et al. (2014). Denote the pathwise derivative of $f$ at $h_0$ in the direction $v \in \mathcal{V} := (L^2(X) - \{h_0\})$ by

$$\frac{\partial f(h_0)}{\partial h}[v] := \lim_{\tau \to 0^+} \frac{f(h_0 + \tau v)}{\tau}$$

and assume it is linear. Let $v^*_K \in \mathcal{V}_K := (B_{K,w} - \{h_{0,K}\})$ be the sieve Riesz representer of $\frac{\partial f(h_0)}{\partial h}[:]$ on $\mathcal{V}_K$, i.e. $v^*_K$ is the unique element of $\mathcal{V}_K$ such that

$$\frac{\partial f(h_0)}{\partial h}[v] = E[v^*_K(X_i)v(X_i)] \text{ for all } v \in \mathcal{V}_K.$$
It is straightforward to verify that

\[ v_K^*(\cdot) = b_w^K(\cdot)' \left( E[b_w^K(X_i) b_w^K(X_i)'] \right)^{-1} \frac{\partial f(h_0)}{\partial h} [b_w^K] = \bar{b}_w^K(\cdot)' \frac{\partial f(h_0)}{\partial h} [\bar{b}_w^K] \]  

(25)

where \( \frac{\partial f(h_0)}{\partial h} [b_w^K] \) is understood to be the vector formed by evaluating \( \frac{\partial f(h_0)}{\partial h} [\cdot] \) at each element of \( b_w^K(\cdot) \).

Let \( \|v_K^*\|_{L^2(X)}^2 = E[|v_K^*(X_i)|^2] \). It is clear that \( \|v_K^*\|_{L^2(X)}^2 = \left( \frac{\partial f(h_0)}{\partial h} [\bar{b}_w^K] \right)' \left( \frac{\partial f(h_0)}{\partial h} [\bar{b}_w^K] \right) \) (25).

Following Chen et al. (2014), we say that \( f \) is a regular (or \( L^2 \)-norm bounded) functional if \( \|v_K^*\|_{L^2(X)} \nearrow \|v^*\|_{L^2(X)} < \infty \) where \( v^* \in \mathcal{V} \) is the unique solution to

\[ \frac{\partial f(h_0)}{\partial h} [v] = E[v^*(X_i) v(X_i)] \quad \text{for all} \quad v \in \mathcal{V}. \]

We say that \( f \) is an irregular (or \( L^2 \)-norm unbounded) functional if \( \|v_K^*\|_{L^2(X)} \nearrow +\infty \). Note that a functional could be irregular but still sup-norm bounded (see Remark 3.1 below).

Given the martingale difference errors (Assumption 2(i)), we can define the sieve variance associated with \( f(\hat{h}) \) as \( V_K := \|v_K^*\|_{sd}^2 := E[(\epsilon_i v_K^*(X_i))^2] \). It is clear that

\[ V_K = \left( \frac{\partial f(h_0)}{\partial h} [b_w^K] \right)' \left( E[b_w^K(X_i) b_w^K(X_i)'] \right)^{-1} E[\epsilon_i^2 b_w^K(X_i) b_w^K(X_i)'] \left( E[b_w^K(X_i) b_w^K(X_i)'] \right)^{-1} \left( \frac{\partial f(h_0)}{\partial h} [b_w^K] \right) \]

(25)

\[ = \left( \frac{\partial f(h_0)}{\partial h} [\bar{b}_w^K] \right)' E[\epsilon_i^2 b_w^K(X_i) \bar{b}_w^K(X_i)] \left( \frac{\partial f(h_0)}{\partial h} [\bar{b}_w^K] \right). \]

The sieve variance \( V_K = \|v_K^*\|_{sd}^2 \) is estimated with the simple plug-in estimator \( \hat{V}_K = \|\hat{v}_K^*\|_{sd}^2 \), where

\[ \|\hat{v}_K^*\|_{sd}^2 = \frac{1}{n} \sum_{i=1}^n \hat{v}_K^*(X_i) (Y_i - \hat{h}(X_i))^2 \]

\[ \hat{v}_K^*(X_i) = b_w^K(X_i)' (B'_w B_w/n) - \frac{\partial f(h_0)}{\partial h} [b_w^K]. \]  

(26)

We first introduce a slight variant of Assumption 2(ii).

Assumption 2 (iv) \( \inf_{x \in \mathcal{X}} E[\epsilon_i^2 |X_i = x] > 0 \), (v) \( \sup_{x \in \mathcal{X}} E[\epsilon_i^2 \{ |\epsilon_i| > \ell(n) \} |X_i = x] \to 0 \) as \( n \to \infty \) for any positive sequence \( \ell : \mathbb{N} \to \mathbb{R}_+ \) with \( \ell(n) \to \infty \) as \( n \to \infty \).

Assumption 2(ii) and (iv) together imply that \( \|v_K^*\|_{L^2(X)}^2 \propto \|v_K^*\|_{sd}^2 = V_K \). Assumption 2(v) is a standard uniform integrability condition, which is not needed for the asymptotic normality of \( f(\hat{h}) \) with i.i.d. data when \( f \) is a regular functional (see, e.g., Chen (2007)).
Before we establish the asymptotic normality of \( f(\tilde{h}) \) under general weak dependence, we need an additional assumption on the joint dependence of \( X_i \) and \( \epsilon_i^2 \), since this is not captured by the martingale difference property of \( \{\epsilon_i\} \) (Assumption 2(i)). Define the \( K \times K \) matrices

\[
\begin{align*}
\hat{\Omega} &= n^{-1} \sum_{i=1}^{n} \epsilon_i^2 \hat{b}_{w}^K(X_i) \hat{b}_{w}^K(X_i)' \\
\Omega &= E[\epsilon_i^2 \hat{b}_{w}^K(X_i) \hat{b}_{w}^K(X_i)']
\end{align*}
\] (27)

**Assumption 8** \( \|\hat{\Omega} - \Omega\| = o_p(1) \).

The following Lemma is a useful technical result that is again derived using our new exponential inequality for sums of weakly dependent random matrices.

**Lemma 3.1** Let Assumptions [1](i), [2](ii)(iii), and [3](iii) hold. Then Assumption 8 is satisfied provided that either (a), (b) or (c) is satisfied:

(a) \( \{(X_i, Y_i)\}_{i=1}^{n} \) is i.i.d. and \( (\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta} \sqrt{\log K}/n = o(1) \);

(b) \( \{(X_i, Y_i)\}_{i=1}^{n} \) is exponentially \( \beta \)-mixing and \( (\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta} \sqrt{\log n}^2/n = o(1) \);

(c) \( \{(X_i, Y_i)\}_{i=1}^{n} \) is algebraically \( \beta \)-mixing at rate \( \gamma \) and \( (\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta} \sqrt{\log K}/n^{\gamma/(1+\gamma)} = o(1) \).

### 3.1 Asymptotic normality of \( f(\tilde{h}) \) for general irregular functionals

Let \( N_{K,n} \) denote a convex neighborhood of \( h_0 \) such that \( \hat{h}, \tilde{h} \in N_{K,n} \text{ wpa1} \). The appropriate neighborhood will depend on the properties of the functional under consideration. For regular and irregular functionals we can typically take \( N_{K,n} \) to be of the form \( N_{K,n} = \{ h \in B_{K,w} : \| h - h_0 \|_{L^2(X)} \leq (\sqrt{K}/n + \| h_0 - h_{0,K} \|_{L^2(X)} \times \log \log n) \} \). However, for sup-norm bounded nonlinear functionals (see Remark 5.1) it may suffice to take \( N_{K,n} = \{ h \in B_{K,w} : \| h - h_0 \|_{L^\infty(X)} < \epsilon \} \) for some fixed \( \epsilon > 0 \), or even \( N_{K,n} = L^\infty(X) \cap B_{K,w} \) for sup-norm bounded linear functionals. Our sup-norm and \( L^2 \) rate results are clearly useful in defining an appropriate neighborhood.

We now introduce some primitive regularity conditions on the functional \( f \).

**Assumption 9** (i) \( v \mapsto \frac{\partial f(h_0)}{\partial h}[v] \) is a linear functional;

(ii) \( \sup_{h\in N_{K,n}} \sqrt{n} \| v_K^* \|_{L^2(X)} 1_f(h) - f(h_0) - \frac{\partial f(h_0)}{\partial h}[h - h_0] = o(1) \) where \( \hat{h}, \tilde{h} \in N_{K,n} \text{ wpa1} \);

(iii) \( \| v_K^* \|_{L^2(X)} \xrightarrow{\text{a.s.}} +\infty, \sqrt{n} \| v_K^* \|_{L^2(X)} \frac{1}{\|f(\tilde{h})\|_{\partial h_0}} \| \tilde{h} - h_0 \| = o_p(1) \).

20
Assumption 9 corresponds to Assumption 3.1 in Chen et al. (2014) and Assumption 2.1 in Chen and Liao (2014) for irregular functionals. We refer the reader to these papers for a detailed discussion and verification of Assumption 9. Note that parts (i) and (ii) of Assumption 9 are automatically satisfied when \( f \) is a linear functional.

**Remark 3.1** Certain linear and nonlinear functionals may be irregular yet may still be bounded with respect to the sup norm. Alternative sufficient conditions for Assumption 9 may be provided for such functionals:

(a) Suppose \( f \) is a linear, irregular functional but that \( f \) is sup-norm bounded, i.e. \( |f(h)| \lesssim \|h\|_\infty \) (e.g. the evaluation functional \( f(h) = h(x) \) for some fixed \( x \in X \) is sup-norm bounded because \( |f(h)| = |h(x)| \leq \|h\|_\infty \)). Then a sufficient condition for Assumption 9 is

\[
\sqrt{n} V_K^{-1/2} \|\hat{h} - h_0\|_\infty \leq \sqrt{n} V_K^{-1/2} \|P_{K,w,n}\|_\infty \|h_0 - h_{0,K}\|_\infty = o_p(1).
\]

When \( \|P_{K,w,n}\|_\infty \lesssim 1 \) and \( \|h_0 - h_{0,K}\|_\infty = O(K^{-p/d}) \) then Assumption 9 is satisfied provided

\[
\sqrt{n} V_K^{-1/2} K^{-p/d} = o(1).
\]

(b) Suppose \( f \) is a nonlinear, irregular functional whose derivative is sup-norm bounded. Then Assumption 9 may be replaced with:

\( (i') \) \( v \mapsto \partial f(h_0)/\partial h \) is a linear functional;

\( (ii') \left| f(h) - f(h_0) - \partial f(h_0)/\partial h \left| h - h_0 \right| \right| \lesssim \left| h - h_0 \right|_\infty^2 \) uniformly for \( h \in N_{K,n} \);

\( (iii') \left| \partial^2 f(h_0)/\partial h^2 \left| h - h_0 \right| \right| \lesssim \left| h - h_0 \right|_\infty \) uniformly for \( h \in N_{K,n} \); and

\( (iv') \hat{h}, \tilde{h} \in N_{K,n} \ w.p.1, \sqrt{n} \|v_K^*\|_{L^2(X)} \left( \left| \hat{h} - h_0 \right|_\infty + \left| \hat{h} - h_0 \right|_\infty^2 + \left| \hat{h} - \tilde{h} \right|_\infty^2 \right) = o_p(1)
\)

where \( N_{K,n} = \{ h \in B_{K,w} : \|h - h_0\|_\infty \leq \epsilon \} \) for some fixed \( \epsilon > 0 \).

For example, Newey (1997) shows that conditions (i')(ii')(iii') are satisfied for consumer surplus functionals in demand estimation.

**Theorem 3.1** Let Assumptions (i), (ii)(iv)(v), (iii), (iv) and (v) hold. Then

\[
\frac{\sqrt{n} f(\hat{h}) - f(h_0)}{V_K^{1/2}} \rightarrow_d N(0, 1)
\]

as \( n, K \to \infty \) provided that either (a) or (b) is satisfied.
(a) \(\{(X_i, Y_i)\}_{i=1}^n\) is i.i.d.;

(b) \(\{X_i\}_{i=1}^n\) is weakly dependent: Assumption 8 holds, and \(\|\tilde{B}_w' \tilde{B}_w / n - I_K\| = o_p(K^{-1/2}).\)

We now consider the special case of irregular but sup-norm bounded linear or nonlinear functionals as discussed in Remark 3.1. The sup-norm convergence rates for series LS estimators in Section 2 are employed to derive asymptotic normality of plug-in estimators of such functionals under weak conditions. To save space, for the weakly dependent case we only present sufficient conditions for asymptotic normality of \(f(\hat{h})\) when the regression error has no more than a finite 4th absolute moment (i.e., \(E|\epsilon_i|^{2+\delta} < \infty\) for some \(0 \leq \delta \leq 2\)). We also take \(\mathcal{X} = [0,1]^d\) and \(w_n = 1\) for all \(n\) for simplicity.

**Corollary 3.1** Let \(f\) be an irregular but sup-norm bounded linear functional, and let Assumptions 1 (with \(\mathcal{X} = [0,1]^d\)), 2(i)(ii)(iv)(v), 6, and 7 hold. Then

\[
\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{V_1^{1/2}} \xrightarrow{d} N(0,1)
\]

as \(n, K \to \infty\) provided that either (a), (b) or (c) is satisfied:

(a) \(\{(X_i, Y_i)\}_{i=1}^n\) is i.i.d.: \(\sqrt{n}V_K^{-1/2}K^{-p/d} = o(1)\) and \((K \log K)/n = o(1)\);

(b) \(\{(X_i, Y_i)\}_{i=1}^n\) is exponentially \(\beta\)-mixing: Assumption 2(iii) also holds, \(\sqrt{n}V_K^{-1/2}K^{-p/d} = o(1)\), and \(K^{(2+\delta)/\delta}(\log n)^2/n = o(1)\) with \(\delta \leq 2\);

(c) \(\{(X_i, Y_i)\}_{i=1}^n\) is algebraically \(\beta\)-mixing at rate \(\gamma\): Assumption 2(iii) also holds, \(\sqrt{n}V_K^{-1/2}K^{-p/d} = o(1)\), and \(K^{(2+\delta)/\delta}(\log K)/n^{\gamma/(1+\gamma)} = o(1)\) with \(\delta \leq 2\).

Corollary 3.1 part (a) extends the weakest known result on pointwise asymptotic normality of spline LS estimators in Huang (2003b) to general sup-norm bounded linear functionals of spline or wavelet series LS estimators.\(^9\)

**Corollary 3.2** Let \(f\) be an irregular but sup-norm bounded nonlinear functional, and let Assumptions 1 (with \(\mathcal{X} = [0,1]^d\)), 2, 6, 7 and 9(i')(ii')(iii') hold. Then

\[
\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{V_1^{1/2}} \xrightarrow{d} N(0,1)
\]

Under the assumption of empirical identifiability (see equation (30)) and other conditions similar to the ones listed in Corollary 3.1 part (a), Chen and Huang (2003) derived the asymptotic normality of plug-in spline LS estimators of sup-norm bounded linear functionals (see their Theorem 4).
as \( n, K \to \infty \) provided that either (a), (b) or (c) is satisfied:

(a) \( \{(X_i, Y_i)\}_{i=1}^n \) is i.i.d.: \( \sqrt{n}V_K^{-1/2}K^{-p/d} = o(1) \) and \( K^{(2+\delta)/\delta}(\log n)/n \lesssim 1 \) with \( \delta < 2 \);

(b) \( \{(X_i, Y_i)\}_{i=1}^n \) is exponentially \( \beta \)-mixing: \( \sqrt{n}V_K^{-1/2}K^{-p/d} = o(1) \) and \( K^{(2+\delta)/\delta}(\log n)^2/n = o(1) \) with \( \delta \leq 2 \);

(c) \( \{(X_i, Y_i)\}_{i=1}^n \) is algebraically \( \beta \)-mixing at rate \( \gamma \): \( \sqrt{n}V_K^{-1/2}K^{-p/d} = o(1) \) and \( K^{(2+\delta)/\delta}(\log K)^{\gamma/(1+\gamma)}/n^{\gamma/(1+\gamma)} = o(1) \) with \( \delta \leq 2 \).

Conditions for weakly dependent data in Corollary 3.2 parts (b) and (c) are natural extensions of those in part (a) for i.i.d. data, which in turn are much weaker than the well-known conditions in Newey (1997) for the asymptotic normality of nonlinear functionals of spline LS estimators, namely \( \sqrt{n}K^{-p/d} = o(1) \), \( K^4/n = o(1) \) and \( \sup_x E[|\epsilon_i|/X_i = x] < \infty \).

### 3.2 Asymptotic normality of sieve t statistics for general functionals

We now turn to the consistent estimation of \( V_K = \|v^*_K\|^2_{sd} \) and feasible asymptotic inference for \( f(h_0) \).

**Assumption 10** \( \|v^*_K\|_{L^2(X)}^{-1} \left\| \frac{\partial f(h)}{\partial h} [\hat{B}_w, \hat{B}_w^T] - \frac{\partial f(h_0)}{\partial h} [\hat{B}_w, \hat{B}_w^T] \right\| = o(1) \) uniformly over \( h \in N_{K,n} \) or \( B_{\epsilon,\infty}(h_0) \).

Note that Assumption 10 is automatically satisfied when \( f \) is a linear functional. It is only required to establish consistency of \( \|v^*_K\|_{sd} \) for a nonlinear functional, and corresponds to Assumption 3.1(iii) of Chen and Liao (2014).

The first part of the following Lemma establishes the consistency of the sieve variance estimator under both the i.i.d. and general weakly dependent data.

**Lemma 3.2** Let Assumptions 7(i)(ii), 8(i)(iv), 9(iii), 10, 11 and 12 hold and \( \|\hat{h} - h_0\|_{\infty,w} = o_p(1) \). Then:

1. \( \left| \frac{\|v^*_K\|_{sd}}{\|v^*_K\|_{sd}} - 1 \right| = o_p(1) \) as \( n, K \to \infty \).

2. Further, if Assumptions 2(v) and 8 hold, then:

\[
\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{\hat{V}_K^{-1/2}} \to_d N(0, 1)
\]

as \( n, K \to \infty \) provided that either (a) \( \{(X_i, Y_i)\}_{i=1}^n \) is i.i.d., or (b) \( \{X_i\}_{i=1}^n \) is weakly dependent with \( \|\hat{B}_w^T \hat{B}_w/n - I_K\| = o_p(K^{-1/2}) \) is satisfied.
Lemma 3.2 can be combined with different sufficient conditions for Assumptions 5, 8 and 9 to yield different special cases of the asymptotic normality of sieve t statistics for general (possibly) nonlinear functionals. We state three special cases below. The following Theorem is applicable to series LS estimators with an arbitrary basis.

**Theorem 3.2** Let Assumptions 1(i)(ii), 2, 3, 4, 9 and 10 hold and $\|\tilde{h} - h_0\|_\infty = o_p(1)$. Then

$$\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{\hat{V}_K^{1/2}} \overset{d}{\rightarrow} N(0, 1)$$

as $n, K \to \infty$ provided that either (a), (b) or (c) is satisfied:

(a) $\{(X_i, Y_i)\}_{i=1}^n$ is i.i.d.: $(\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta} \sqrt{(\log n)/n} = o(1)$;

(b) $\{(X_i, Y_i)\}_{i=1}^n$ is exponentially $\beta$-mixing: $\max(\sqrt{K}, (\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta}) \times (\zeta_{K,n}\lambda_{K,n}) \sqrt{(\log n)/n} = o(1)$;

(c) $\{(X_i, Y_i)\}_{i=1}^n$ is algebraically $\beta$-mixing at rate $\gamma$: $\max(\sqrt{K}, (\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta}) \times (\zeta_{K,n}\lambda_{K,n}) \sqrt{\log n/\gamma n^{1/(1+\gamma)}} = o(1)$.

The following Corollaries are direct consequences of Theorem 3.2 for linear and nonlinear sup-norm bounded functionals, with spline or wavelet bases. For simplicity, we take $w_n = 1$ for all $n$ and $X = [0, 1]^d$.

**Corollary 3.3** Let Assumptions 1 (with $X = [0, 1]^d$), 2 and 7 hold for a sup-norm bounded linear functional. Then

$$\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{\hat{V}_K^{1/2}} \overset{d}{\rightarrow} N(0, 1)$$

as $n, K \to \infty$ provided that either (a), (b) or (c) is satisfied:

(a) $\{(X_i, Y_i)\}_{i=1}^n$ is i.i.d.: $\sqrt{n}V_K^{-1/2}K^{-p/d} = o(1)$ and $K^{(2+\delta)/\delta}(\log n)/n = o(1)$;

(b) part (b) of Corollary 3.1;

(c) part (c) of Corollary 3.1.

**Corollary 3.4** Let Assumptions 1 (with $X = [0, 1]^d$), 2, 6, 7, 9(i')(ii')(iii') and 10 hold for a nonlinear functional. Then

$$\frac{\sqrt{n}(f(\hat{h}) - f(h_0))}{\hat{V}_K^{1/2}} \overset{d}{\rightarrow} N(0, 1)$$
as \( n, K \to \infty \) provided that either (a), (b) or (c) is satisfied:

(a) \( \{(X_i, Y_i)\}_{i=1}^{n} \) is i.i.d.: \( \sqrt{n}V_{K}^{-1/2}K^{-p/d} = o(1) \) and \( K^{(2+\delta)/\delta}(\log n)/n = o(1) \) with \( \delta < 2 \);

(b) part (b) of Corollary 3.2;

(c) part (c) of Corollary 3.2.

Previously, Newey (1997) required that \( \sup_x E[\epsilon_i^4|X_i = x] < \infty \) and \( K^4/n = o(1) \) in order to establish asymptotic normality of student \( t \) statistics for nonlinear functionals with i.i.d. data. Our sufficient conditions are weaker and allow for weakly dependent data with heavy-tailed errors.

4 Useful results on random matrices

4.1 An exponential inequality for sums of weakly dependent random matrices

In this section we derive a new Bernstein-type inequality for sums of random matrices formed from absolutely regular (\( \beta \)-mixing) sequences, where the dimension, norm, and variance measure of the random matrices are allowed to grow with the sample size. This inequality is particularly useful for establishing sharp convergence rates for semi/nonparametric sieve estimators with weakly dependent data. We first recall an inequality of Tropp (2012) for independent random matrices.

**Theorem 4.1** (Tropp (2012)) Let \( \{\Xi_i\}_{i=1}^{n} \) be a finite sequence of independent random matrices with dimensions \( d_1 \times d_2 \). Assume \( E[\Xi_i] = 0 \) for each \( i \) and \( \max_{1 \leq i \leq n} \|\Xi_i\| \leq R_n \), and define

\[
\sigma_n^2 = \max \left\{ \left\| \sum_{i=1}^{n} E[\Xi_i] \Xi_i' \right\|, \left\| \sum_{i=1}^{n} E[\Xi_i'] \Xi_i \right\| \right\}.
\]

Then for all \( t \geq 0 \),

\[
P \left( \left\| \sum_{i=1}^{n} \Xi_i \right\| \geq t \right) \leq (d_1 + d_2)\exp \left( \frac{-t^2/2}{\sigma_n^2 + R_n t/3} \right).
\]

**Corollary 4.1** Under the conditions of Theorem 4.1 if \( R_n \sqrt{\log(d_1 + d_2)} = o(\sigma_n) \) then

\[
\left\| \sum_{i=1}^{n} \Xi_{i,n} \right\| = O_p(\sigma_n \sqrt{\log(d_1 + d_2)}).
\]
When \( \{X_i\}_{i=-\infty}^\infty \) is i.i.d., Corollary 4.1 is used to provide weak low-level sufficient conditions under which \( \|\hat{B}_w B_w / n - I_K\| = o_p(1) \) holds (see Lemma 2.1).

We now provide an extension of Theorem 4.1 and Corollary 4.1 for matrix-valued functions of \( \beta \)-mixing sequences. The \( \beta \)-mixing coefficient between two \( \sigma \)-algebras \( \mathcal{A} \) and \( \mathcal{B} \) is defined as

\[
\beta(\mathcal{A}, \mathcal{B}) = \frac{1}{2} \sup_{(i,j) \in I \times J} \left| \mathbb{P}(A_i \cap B_j) - \mathbb{P}(A_i)\mathbb{P}(B_j) \right|
\]

with the supremum taken over all finite partitions \( \{A_i\}_{i \in I} \subset \mathcal{A} \) and \( \{B_j\}_{j \in J} \subset \mathcal{B} \) of \( \Omega \) (see, e.g., Bradley (2005)). The \( q \)th \( \beta \)-mixing coefficient of \( \{X_i\}_{i=-\infty}^\infty \) is defined as

\[
\beta(q) = \sup_i \beta(\sigma(\ldots, X_{i-1}, X_i), \sigma(X_{i+q}, X_{i+q+1}, \ldots)) .
\]

The process \( \{X_i\}_{i=-\infty}^\infty \) is said to be algebraically \( \beta \)-mixing at rate \( \gamma \) if \( q^\gamma \beta(q) = o(1) \) for some \( \gamma > 1 \), and exponentially \( \beta \)-mixing if \( \beta(q) \leq c \exp(-\gamma q) \) for some \( \gamma > 0 \) and \( c \geq 0 \). The following extension of Theorem 4.1 is made using Berbee’s Lemma and a coupling argument.

**Theorem 4.2** Let \( \{X_i\}_{i=-\infty}^\infty \) be a \( \beta \)-mixing sequence and let \( \Xi_{i,n} = \Xi_n(X_i) \) for each \( i \) where \( \Xi_n : \mathcal{X} \rightarrow \mathbb{R}^{d_1 \times d_2} \) is a sequence of measurable \( d_1 \times d_2 \) matrix-valued functions. Assume \( E[\Xi_{i,n}] = 0 \) and \( \|\Xi_{i,n}\| \leq R_n \) for each \( i \) and define \( s_n^2 = \max_{1 \leq i,j \leq n} \max\{\|E[\Xi_{i,n}\Xi'_{j,n}]\|, \|E[\Xi'_{i,n}\Xi_{j,n}]\|\} \). Let \( q \) be an integer between \( 1 \) and \( n/2 \) and let \( I_r = q[n/q] + 1, \ldots, n \) when \( q[n/q] < n \) and \( I_r = \emptyset \) when \( q[n/q] = n \). Then for all \( t \geq 0 \),

\[
\mathbb{P}\left( \left\| \sum_{i=1}^n \Xi_{i,n} \right\| \geq 6t \right) \leq \frac{n}{q} \beta(q) + \mathbb{P}\left( \left\| \sum_{i \in I_r} \Xi_{i,n} \right\| \geq t \right) + 2(d_1 + d_2)\exp\left( \frac{-t^2/2}{nq s_n^2 + qR_n t^3/3} \right)
\]

(where \( \|\sum_{i \in I_r} \Xi_{i,n}\| := 0 \) whenever \( I_r = \emptyset \)).

**Corollary 4.2** Under the conditions of Theorem 4.2 if \( q = q(n) \) is chosen s.t. \( \frac{n}{q} \beta(q) = o(1) \) and \( R_n \sqrt{q \log(d_1 + d_2)} = o(s_n \sqrt{n}) \) then

\[
\left\| \sum_{i=1}^n \Xi_{i,n} \right\| = O_p(s_n \sqrt{nq \log(d_1 + d_2))} .
\]

When the regressors \( \{X_i\}_{i=-\infty}^\infty \) are \( \beta \)-mixing, Corollary 4.2 is used to provide weak low-level sufficient conditions under which \( \|\hat{B}_w B_w / n - I_K\| = o_p(1) \) holds (see Lemma 2.2).
We note that both Theorem 4.2 and Corollary 4.2 allow for non-identically distributed beta-mixing sequences. So the convergence rate and the inference results in previous sections could be extended to non-identically distributed regressors \( \{X_i\}_{i=-\infty}^{\infty} \) as well, except that notation and regularity conditions will be slightly more complicated.

### 4.2 Empirical identifiability

We now provide a readily verifiable condition under which the theoretical and empirical \( L^2 \) norms are equivalent over a (weighted) linear sieve space \( \mathcal{A} \). This equivalence, referred to by Huang (2003b) as *empirical identifiability*, has several applications in nonparametric sieve estimation. In nonparametric series LS estimation, empirical identifiability ensures that the estimator is the orthogonal projection of \( Y \) onto the linear sieve space under the empirical inner product and is uniquely defined \( \mathcal{A} \) (Huang, 2003b). Empirical identifiability is also used to establish the large-sample properties of sieve conditional moment estimators (see, e.g., Chen and Pouzo (2012)). A sufficient condition for empirical identifiability is now cast in terms of convergence of a random matrix, which we verify for i.i.d. and \( \beta \)-mixing sequences.

Recall that \( L^2(X) \) denotes the space of functions \( f : X \to \mathbb{R} \) such that \( E[f(X_i)^2] < \infty \). A (linear) subspace \( \mathcal{A} \subseteq L^2(X) \) is said to be *empirically identifiable* if \( \frac{1}{n} \sum_{i=1}^{n} b(X_i)^2 = 0 \) implies \( b = 0 \). A sequence of spaces \( \{\mathcal{A}_K : K \geq 1\} \subseteq L^2(X) \) is empirically identifiable \( \mathcal{A} \) as \( K = K(n) \to \infty \) with \( n \) if

\[
\lim_{n \to \infty} \mathbb{P} \left( \sup_{a \in \mathcal{A}_K} \left| \frac{1}{n} \sum_{i=1}^{n} a(X_i)^2 - E[a(X_i)^2] \right| > t \right) = 0 \quad (30)
\]

for any \( t > 0 \). Huang (1998) verifies (30) for i.i.d. data using a chaining argument. Chen and Pouzo (2012) use this result to establish convergence of sieve conditional moment estimators. However, it may be difficult to verify (30) via chaining arguments for certain types of weakly dependent sequences.

To this end, the following is a readily verifiable sufficient condition for empirical identifiability for (weighted) linear sieve spaces given by \( \mathcal{B}_{K,w} = \text{clsp}\{b_{K1}w_n, \ldots, b_{KK}w_n\} \).

**Condition 4.1** \( \lambda_{\text{min}}(E[b_{w}^{K}(X_i)b_{w}^{K}(X_i)']) > 0 \) for each \( K \) and \( \|\tilde{B}_w^t \tilde{B}_w/n - I_K\| = o_p(1) \).

**Lemma 4.1** If \( \lambda_{\text{min}}(E[b_{w}^{K}(X_i)b_{w}^{K}(X_i)']) > 0 \) for each \( K \) then

\[
\sup_{b \in \mathcal{B}_{K,w}} \left| \frac{1}{n} \sum_{i=1}^{n} b(X_i)^2 - E[b(X_i)^2] \right| = \|\tilde{B}_w^t \tilde{B}_w/n - I_K\|^2.
\]
Corollary 4.3 If Condition 4.1 holds then $B_{K,w}$ is empirically identifiable wpa1.

Condition 4.1 is therefore a sufficient condition for (30) to hold for the linear sieve space $B_{K,w}$.

Remark 4.1 Consider the compact support case in which $\mathcal{X} = [0,1]^d$ and $w_n(x) = 1$ for all $x \in \mathcal{X}$ and all $n$ (so that $b_{K,k}(x)w_n(x) = b_{K,k}(x)$ for all $n$ and $K$) and suppose the density of $X_i$ is uniformly bounded away from zero and infinity over $\mathcal{X}$. (1) For i.i.d. regressors (and $\lambda_{K,n} \lesssim 1$), previously Huang (1998) establishes equivalence of the theoretical and empirical $L^2$ norms over the sieve space via a chaining argument with $\zeta_{K,n} K/n = o(1)$. Huang (2003b) relaxes this to $K(\log n)/n = o(1)$ for a polynomial spline basis. Our Lemma 2.1 shows that, in fact, $\zeta_{K,n}\sqrt{(\log K)/n} = o(1)$ is sufficient with an arbitrary linear sieve (provided $\lambda_{K,n} \lesssim 1$). (2) For strictly stationary beta-mixing regressors (and $\lambda_{K,n} \lesssim 1$), Lemma 2.2 shows the equivalence of the theoretical and empirical $L^2$ norms over any linear sieve space under either $\zeta_{K,n}\sqrt{(\log n)^2/n} = o(1)$ for exponential beta-mixing, or $\zeta_{K,n}\sqrt{(\log K)/n^{\gamma/(1+\gamma)}} = o(1)$ for algebraic beta-mixing.

5 Sup-norm stability of $L^2(\mathcal{X})$ projection onto wavelet sieves

In this section we show that the $L^2(\mathcal{X})$ orthogonal projection onto (tensor product) compactly supported wavelet bases is stable in sup norm as the dimension of the space increases. Consider the orthogonal projection operator $P_K$ defined in expression (16) where the elements of $b^K$ span the tensor products of $d$ univariate wavelet spaces $\text{Wav}(K_0, [0,1])$. We show that its $L^\infty$ operator norm $\|P_K\|_\infty$ (see expression (17)) is stable, in the sense that $\|P_K\|_\infty \lesssim 1$ as $K \to \infty$. We also show that the empirical $L^2$ projection $P_{K,n}$ onto the wavelet sieve is stable in sup norm wpa1. This result is used to establish that series LS estimators with (tensor-product) wavelet bases attain their optimal sup-norm rates. A variant of this result for projections arising in series two-stage LS was used in an antecedent of this paper (Chen and Christensen, 2013) but its proof was omitted for brevity.

The following Theorem presents our result for the stability of the projection with respect to the $L^2(\mathcal{X})$ inner product.

Theorem 5.1 Let $\mathcal{X} \supseteq [0,1]^d$ and let the density $f_X$ of $X_i$ be such that $0 < \inf_{x \in [0,1]^d} f_X(x) \leq \sup_{x \in [0,1]^d} f_X(x) < \infty$. Let $B_K$ be the tensor product of $d$ univariate wavelet spaces $\text{Wav}(K_0, [0,1])$ where $\text{Wav}(K_0, [0,1])$ is as described in Section 6 and $K = 2^{dJ}$ and $K_0 = 2^J > 2N$. Then: $\|P_K\|_\infty \lesssim 1$. 

28
We now present conditions under which the empirical projection onto a tensor-product wavelet basis is stable wp1. Here the projection operator is

\[ P_{K,n}h(x) = b^K(x)' \left( \frac{B'B}{n} \right) - \frac{1}{n} \sum_{i=1}^{n} b^K(X_i)h(X_i) \]

where the elements of \( b^K \) span the tensor products of \( d \) univariate spaces \( \text{Wav}(K_0, [0, 1]) \). The following Theorem states simple sufficient conditions for \( \| P_{K,n} \|_\infty \lesssim 1 \) wp1.

**Theorem 5.2** Let conditions stated in Theorem 5.1 hold. Then \( \| P_{K,n} \|_\infty \lesssim 1 \) wp1 provided that either (a), (b), or (c) is satisfied:

(a) \( \{X_i\}_{i=1}^{n} \) are i.i.d. and \( \sqrt{K \log n}/n = o(1) \)

(b) \( \{X_i\}_{i=1}^{n} \) are exponentially \( \beta \)-mixing and \( \sqrt{K (\log n)^2}/n = o(1) \), or

(c) \( \{X_i\}_{i=1}^{n} \) are algebraically \( \beta \)-mixing at rate \( \gamma \) and \( \sqrt{(K \log n)/n^{\gamma/(1+\gamma)}} = o(1) \).

6 **Brief review of B-spline and wavelet sieve spaces**

We first outline univariate B-spline and wavelet sieve spaces on \([0, 1]\), then deal with the multivariate case by constructing a tensor-product sieve basis.

**B-splines** B-splines are defined by their order \( r \geq 1 \) (or degree \( r - 1 \geq 0 \)) and number of interior knots \( m \geq 0 \). Define the knot set

\[ 0 = t_{-(r-1)} = \ldots = t_0 \leq t_1 \leq \ldots \leq t_m \leq t_{m+1} = \ldots = t_{m+r} = 1. \] (31)

We generate a \( L^\infty \)-normalized B-spline basis recursively using the De Boor relation (see, e.g., Chapter 5 of DeVore and Lorentz (1993)) then appropriately rescale the basis functions. Define the interior intervals \( I_1 = [t_0, t_1], \ldots, I_m = [t_m, t_{m+1}] \) and generate a basis of order 1 by setting

\[ N_{j,1}(x) = 1_{I_j}(x) \] (32)
for \( j = 0, \ldots, m \), where \( 1_{I_j}(x) = 1 \) if \( x \in I_j \) and \( 1_{I_j}(x) = 0 \) otherwise. Bases of order \( r > 1 \) are generated recursively according to

\[
N_{j,r}(x) = \frac{x - t_j}{t_{j+r-1} - t_j} N_{j,r-1}(x) + \frac{t_{j+r} - x}{t_{j+r} - t_{j+1}} N_{j+1,r-1}(x)
\]

for \( j = -(r-1), \ldots, m \) where we adopt the convention \( \frac{1}{0} := 0 \). Finally, we rescale the basis by multiplying each \( N_{j,r} \) by \((m+r)^{1/2}\) for \( j = -(r-1), \ldots, m \). This results in a total of \( K = m + r \) splines of order \( r \). Each spline is a polynomial of degree \( r - 1 \) on each interior interval \( I_1, \ldots, I_m \) and is \((r-2)\)-times continuously differentiable on \((0, 1)\) whenever \( r > 2 \). The mesh ratio is defined as

\[
\text{mesh}(K) = \frac{\max_{0 \leq j \leq m}(t_{j+1} - t_j)}{\min_{0 \leq j \leq m}(t_{j+1} - t_j)}.
\]

We let the space \( \text{BSpl}(K, [0, 1]) \) be the closed linear span of these \( K = m + r \) splines. The space \( \text{BSpl}(K, [0, 1]) \) has uniformly bounded mesh ratio if \( \text{mesh}(K) \leq \kappa \) for all \( N \geq 0 \) and some \( \kappa \in (0, \infty) \).

We let \( \text{BSpl}(K, [0, 1], \gamma) \) denote the space \( \text{BSpl}(K, [0, 1]) \) with degree \( \gamma \) and uniformly bounded mesh ratio. See De Boor (2001) and Schumaker (2007) for further details.

**Wavelets**  
We construct a wavelet basis with support \([0, 1]\) following Cohen, Daubechies, and Vial (1993). Let \((\varphi, \psi)\) be a Daubechies pair such that \( \varphi \) has support \([-N+1, N] \). Given \( j \) such that \( 2^j - 2N > 0 \), the orthonormal (with respect to the \( L^2([0,1]) \) inner product) basis for the space \( V_j \) consists of \( 2^j - 2N \) interior scaling functions of the form \( \varphi_{j,k}(x) = 2^{j/2} \varphi(2^j x - k) \), each of which has support \([2^{-j}(-N+1+k), 2^{-j}(N+k)]\) for \( k = N, \ldots, 2^j - N - 1 \). These are augmented with \( N \) left scaling functions of the form \( \psi_{j,k}^0(x) = 2^{j/2} \varphi_k'(2^j x) \) for \( k = 0, \ldots, N - 1 \) (where \( \varphi_k^0, \ldots, \varphi_k^{N-1} \) are fixed independent of \( j \)), each of which has support \([0, 2^{-j}(N+k)]\), and \( N \) right scaling functions of the form \( \psi_{j,2^j-k}^r(x) = 2^{j/2} \varphi_k^r(2^j(x-1)) \) for \( k = 1, \ldots, N \) (where \( \varphi_1^r, \ldots, \varphi_N^r \) are fixed independent of \( j \)), each of which has support \([1 - 2^{-j}(1 - N - k), 1]\). The resulting \( 2^j \) functions \( \psi_{j,0}^0, \ldots, \psi_{j,N-1}^0, \varphi_{j,N-1}^0, \varphi_{j,N}^1, \ldots, \varphi_{j,2^j-N-1}^1, \varphi_{j,2^j-N}^1, \psi_{j,2^j-N-1}^1, \ldots, \psi_{j,2^j-1}^1 \) form an orthonormal basis (with respect to the \( L^2([0,1]) \) inner product) for the subspace they span, denoted \( V_j \).

An orthonormal wavelet basis for the space \( V_{j+1} \), defined as the orthogonal complement of \( V_j \) in \( V_{j+1} \), is similarly constructed from the mother wavelet. This results in an orthonormal basis of \( 2^j \) functions \( \psi_{j,0}^0, \ldots, \psi_{j,N-1}^0, \psi_{j,N}^1, \ldots, \psi_{j,2^j-N-1}^1, \psi_{j,2^j-N}^1, \ldots, \psi_{j,2^j-1}^1 \). To simplify notation we ignore the
0 and 1 superscripts on the left and right wavelets and scaling functions henceforth.

Let \( J_0 \) and \( J \) be integers such that \( 2^{J_0} \leq 2^J < 2N \). A wavelet space at resolution level \( J \) is the set of \( 2^J \) functions given by

\[
\text{Wav}(J) = \left\{ \sum_{k=0}^{2^{J_0}-1} a_{J_0,k} \varphi_{J_0,k} + \sum_{j=J_0}^{J} \sum_{k=0}^{2^j-1} b_{j,k} \psi_{j,k} : a_{J_0,k}, b_{j,k} \in \mathbb{R} \right\}. \tag{35}
\]

The spaces \( V_j \) and \( W_j \) are constructed so that \( V_{j+1} = V_j \oplus W_j \) for all \( j \) with \( 2^j - 2N > 0 \). Therefore, we can reexpress \( \text{Wav}(J) \) as

\[
\text{Wav}(J) = \left\{ \sum_{k=0}^{2^{J_0}-1} a_{J,k} \varphi_{J,k} : a_{J,k} \in \mathbb{R} \right\}. \tag{36}
\]

The orthogonal projection onto \( \text{Wav}(J) \) is therefore the same, irrespective of whether we use the bases for \( V_J \) or \( V_{J_0} \oplus W_{J_0} \oplus \ldots \oplus W_J \). Note that, by the support of the \( \varphi_{J,0}, \ldots, \varphi_{J,2^J-1} \), the support of at most \( 2N-1 \) basis functions overlaps on a set of positive Lebesgue measure. We use this local support to bound the orthogonal projection operator onto (tensor product) wavelet bases in Section 5.

We say that \( \text{Wav}(K, [0, 1]) \) has regularity \( \gamma \) if \( N \geq \gamma \), and write \( \text{Wav}(K, [0, 1], \gamma) \) for a wavelet space of regularity \( \gamma \) with continuously differentiable basis functions. This particular wavelet basis has been used in Chen and Reiss (2011), Kato (2013) and Chen and Christensen (2013) for sieve nonparametric instrumental variables regression. And it also satisfies \( \zeta_{K,n} \lesssim \sqrt{K} \) with \( K = 2^J \) (see, e.g., p. 2240 of Gobet, Hoffmann, and Reiss (2004) or p. 2377 of Kato (2013)). See Johnstone (2013) for further details.

**Tensor products** We construct tensor product B-spline or wavelet bases for \([0, 1]^d\) as follows. First, for \( x = (x_1, \ldots, x_d) \in [0, 1]^d \) we construct \( d \) B-spline or wavelet bases for \([0, 1]\). We then form the tensor product basis by taking the product of the elements of each of the univariate bases. Therefore, \( b^K(x) \) may be expressed as

\[
b^K(x) = \bigotimes_{l=1}^{d} b^{K_0}(x_l) \tag{37}
\]

where the elements of each vector \( b^{K_0}(x_l) \) span BSpl\((K_0, [0, 1], \gamma)\) with \( K_0 = m + r \) for \( l = 1, \ldots, d \), or span Wav\((K_0, [0, 1], \gamma)\) with \( K_0 = 2^J \) for \( l = 1, \ldots, d \). We let BSpl\((K, [0, 1]^d, \gamma)\) and Wav\((K, [0, 1]^d, \gamma)\) denote the resulting tensor-product spaces spanned by the \( K = (m + r)^d \) or \( K = 2^{dJ} \) elements of \( b^K \).
7 Proofs

7.1 Proofs for Section 2

Proof of Lemma 2.1. Follows from Corollary 1.1 by setting $\Xi_{i,n} = n^{-1}(\tilde{b}_w^K(X_i)\tilde{b}_w^K(X_i)' - I_K)$ and noting that $R_n \leq n^{-1}(\zeta_{K,n}^2 \lambda_{K,n}^2 + 1)$, and $\sigma_n^2 \leq n^{-1}(\zeta_{K,n}^2 \lambda_{K,n}^2 + 1)$.

Proof of Lemma 2.2. Follows from Corollary 1.2 by setting $\Xi_{i,n} = n^{-1}(\tilde{b}_w^K(X_i)\tilde{b}_w^K(X_i)' - I_K)$ and noting that $R_n \leq n^{-1}(\zeta_{K,n}^2 \lambda_{K,n}^2 + 1)$, and $\sigma_n^2 \leq n^{-2}(\zeta_{K,n}^2 \lambda_{K,n}^2 + 1)$.

Proof of Lemma 2.3. By rotational invariance, we may rescale $\hat{h}$ and $\bar{h}$ to yield

$$\hat{h}(x) - \bar{h}(x) = \tilde{b}_w^K(x)'(\tilde{B}_w^t\tilde{B}_w/n) - \tilde{B}_w' e/n$$  \hspace{1cm} (38)

where $e = (\epsilon_1, \ldots, \epsilon_n)'$.

Let $\bar{h} = \hat{h} - \bar{h}$ to simplify notation. By the mean value theorem, Assumptions 3(i) and 4(i)(iii), for any $(x, x^*) \in \mathcal{D}_n^2$ we have

$$|\bar{h}(x) - \bar{h}(x^*)| = |(\tilde{b}_w^K(x) - \tilde{b}_w^K(x^*))'(\tilde{B}_w^t\tilde{B}_w/n) - \tilde{B}_w' e/n|$$  \hspace{1cm} (39)

$$= |(x - x^*)'(\nabla \tilde{b}_w^K(x^*))'(\tilde{B}_w^t\tilde{B}_w/n) - \tilde{B}_w' e/n|$$  \hspace{1cm} (40)

$$\leq C_{\nabla} \lambda_{K,n} n^{\omega_1} K^{\omega_2} \|x - x^*\| \|\tilde{B}_w^t\tilde{B}_w/n\| \|\tilde{B}_w' e/n\|$$  \hspace{1cm} (41)

for some $x^{**}$ in the segment between $x$ and $x^*$ and some finite constant $C_{\nabla}$ (independent of $x, x^*, n, K$). Now, $\|(\tilde{B}_w^t\tilde{B}_w/n)^{-1}\| = O_p(1)$ by Assumption 5, and we may deduce by Markov’s inequality (under Assumptions 2(i)(ii)) that $\|\tilde{B}_w' e/n\| = O_p(\sqrt{K/n})$. It follows that

$$\limsup_{n \to \infty} \mathbb{P}\left( C_{\nabla} \|(\tilde{B}_w^t\tilde{B}_w/n)^{-1}\| \|\tilde{B}_w' e/n\| > \bar{M} \right) = 0$$  \hspace{1cm} (42)

for any fixed $\bar{M} > 0$ (since condition (i) implies $K/n = o(1)$). Let $\mathcal{B}_n$ denote the event on which $C_{\nabla} \|(\tilde{B}_w^t\tilde{B}_w/n)^{-1}\| \|\tilde{B}_w' e/n\| \leq \bar{M}$ and observe that $\mathbb{P}(\mathcal{B}_n^c) = o(1)$. On $\mathcal{B}_n$, for any $C \geq 1$, a finite positive $\eta_1 = \eta_1(C)$ and $\eta_2 = \eta_2(C)$ can be chosen such that

$$C_{\nabla} \lambda_{K,n} n^{\omega_1} K^{\omega_2} \|x - x^*\| \|(\tilde{B}_w^t\tilde{B}_w/n)^{-1}\| \|\tilde{B}_w' e/n\| \leq C\zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n}$$  \hspace{1cm} (43)

whenever $\|x - x^*\| \leq \eta_1 n^{-\eta_2}$, by Assumption 4(ii). Let $\mathcal{S}_n$ be the smallest subset of $\mathcal{D}_n$ such that for
each \( x \in D_n \) there exists a \( x_n \in S_n \) with \( \| x_n - x \| \leq \eta_1 n^{-\eta_2} \). For any \( x \in D_n \) let \( x_n(x) \) denote the \( x_n \in S_n \) nearest (in Euclidean distance) to \( x \). Then on \( B_n \) we have

\[
| \tilde{h}(x) - \tilde{h}(x_n(x)) | \leq C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \quad (44)
\]

for any \( x \in D_n \).

Using the fact that \( P(A) \leq P(A \cap B) + P(B^c) \), we obtain

\[
P \left( \| \tilde{h} \|_\infty \geq 4C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right)
\leq P \left( \left\{ \| \tilde{h} \|_\infty \geq 4C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right\} \cap B_n \right) + P(B_n^c) \quad (45)
\]

\[
\leq P \left( \left\{ \sup_{x \in X} | \tilde{h}(x) - \tilde{h}(x_n(x)) | \geq 2C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right\} \cap B_n \right) + P(B_n^c) \quad (46)
\]

\[
= P \left( \left\{ \max_{x_n \in S_n} | \tilde{h}(x_n) | \geq 2C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right\} \cap B_n \right) + o(1) \quad (47)
\]

where the final line is by (44) and the fact that \( P(B_n^c) = o(1) \). The arguments used to control expression (47) differ depending upon whether or not \( \{(X_i, Y_i)\}_{i=1}^n \) is i.i.d.

With i.i.d. data, first let \( A_n \) denote the event on which \( \| (\tilde{B}_w \tilde{B}_w / n) - I_K \| \leq \frac{1}{2} \) and observe that \( P(A_n^c) = o(1) \) because \( \| \tilde{B}_w \tilde{B}_w / n - I_K \| = o_p(1) \). Let \( \{ A_n \} \) denote the indicator function of \( A_n \), let \( \{ M_n : n \geq 1 \} \) be an increasing sequence diverging to +\( \infty \), and define

\[
\epsilon_{1,i,n} := \epsilon_i \{ | \epsilon_i | \leq M_n \} - E[\epsilon_i \{ | \epsilon_i | \leq M_n \}|X_i] \quad (48)
\]

\[
\epsilon_{2,i,n} := \epsilon_i - \epsilon_{1,i,n} \quad (49)
\]

\[
G_{i,n}(x_n) := \tilde{b}_w^K(x_n)'(\tilde{B}_w' \tilde{B}_w / n) - \tilde{b}_w^K(X_i) \{ A_n \}. \quad (50)
\]
Since $\mathbb{P}(A \cap B) \leq \mathbb{P}(A)$ and $\mathbb{P}(A) \leq \mathbb{P}(A \cap B) + \mathbb{P}(B^c)$, we have

$$\mathbb{P}\left(\left\{ \max_{x_n \in S_n} |\tilde{h}(x_n)| \geq 2C\zeta_{K,n}\lambda_{K,n}\sqrt{\log n}/n \right\} \cap B_n \right)$$

$$\leq \mathbb{P}\left(\left\{ \max_{x_n \in S_n} |\tilde{h}(x_n)| \geq 2C\zeta_{K,n}\lambda_{K,n}\sqrt{\log n}/n \right\} \cap A_n \right) + \mathbb{P}(A_n^c)$$

$$\leq (\#S_n) \max_{x_n \in S_n} \mathbb{P}\left(\left\{ \left| \frac{1}{n} \sum_{i=1}^{n} G_{i,n}(x_n)\epsilon_{1,i,n} \right| \geq C\zeta_{K,n}\lambda_{K,n}\sqrt{\log n}/n \right\} \cap A_n \right)$$

$$+ \mathbb{P}\left(\left\{ \max_{x_n \in S_n} \left| \frac{1}{n} \sum_{i=1}^{n} G_{i,n}(x_n)\epsilon_{2,i,n} \right| \geq C\zeta_{K,n}\lambda_{K,n}\sqrt{\log n}/n \right\} \cap A_n \right) + \mathbb{P}(A_n^c). \quad (51a)$$

Control of $\mathbb{P}(51a)$: Note that $\|B_{w}\tilde{B}_{w}/n\| \leq 2$ on $A_n$. Therefore, by the Cauchy-Schwarz inequality and definition of $\epsilon_{1,i,n}$ and $\zeta_{K,n}$, $\lambda_{K,n}$, we have:

$$|n^{-1}G_{i,n}(x_n)\epsilon_{1,i,n}| \leq \frac{\zeta_{K,n}^2\lambda_{K,n}^2}{n}. \quad (52)$$

Let $E[\cdot | X_i^n]$ denote expectation conditional on $X_1, \ldots, X_n$. Assumption 2(ii) in the i.i.d. data case implies that $\sup_x E[\epsilon_i^2 | X_i = x] < \infty$. Therefore,

$$\sum_{i=1}^{n} E[(n^{-1}G_{i,n}(x_n)\epsilon_{1,i,n})^2 | X_i^n]$$

$$= \frac{1}{n^2} \sum_{i=1}^{n} E[\epsilon_{1,i,n}^2 | X_i^n] b^K_{w}(x_n')(B_{w}'\tilde{B}_{w}/n)^{-1} b^K_{w}(X_i)\tilde{b}_w^K(X_i)' \{A_n\} (B_{w}'\tilde{B}_{w}/n)^{-1} \tilde{b}_w^K(x_n)$$

$$\leq \frac{1}{n^2} \sum_{i=1}^{n} b^K_{w}(x_n') (B_{w}'\tilde{B}_{w}/n)^{-1} \tilde{b}_w^K(X_i)\tilde{b}_w^K(X_i)' \{A_n\} (B_{w}'\tilde{B}_{w}/n)^{-1} \tilde{b}_w^K(x_n)$$

$$= \frac{1}{n} \tilde{b}_w^K(x_n') E[(B_{w}'\tilde{B}_{w}/n)^{-1} (B_{w}'\tilde{B}_{w}/n)^{-1} \tilde{b}_w^K(x_n') \{A_n\} (B_{w}'\tilde{B}_{w}/n)^{-1} \tilde{b}_w^K(x_n)] \leq \frac{\zeta_{K,n}^2\lambda_{K,n}^2}{n}. \quad (53)$$

Bernstein’s inequality for independent random variables (see, e.g., pp. 192–193 of Pollard (1984)) then
provides that
\[
\left(\#S_n\right) \max_{x_n \in S_n} \mathbb{P}\left( \left\{ \frac{1}{n} \sum_{i=1}^{n} G_i,n(x_n) \epsilon_{1,i,n} \geq C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right\} \cap A_n \right| X_1^n \right)
\]
\[
\lesssim n^{\nu_1 + \nu_2} \exp \left\{ -\frac{C_1 \zeta_{K,n} \lambda_{K,n}^2 (\log n)/n}{C_2 \zeta_{K,n} \lambda_{K,n}^2 M_n} \right\}
\]
\[
\lesssim \exp \left\{ \log n - \frac{C_2 \zeta_{K,n} \lambda_{K,n}^2 (\log n)/n}{C_3 \zeta_{K,n} \lambda_{K,n}^2 M_n} \right\}
\]
\[
\exp \left\{ \log n - \frac{C \sqrt{n \log n}}{C_4 \zeta_{K,n} \lambda_{K,n} M_n} \right\}
\]
for finite positive constants $C_1, \ldots, C_4$ (independent of $X_1, \ldots, X_n$). Thus (51a) vanishes asymptotically for all sufficiently large $C$ provided $M_n = O(\zeta_{K,n}^{-1} \lambda_{K,n}^{-1} \sqrt{n/(\log n)})$.

Control of the leading term in (51b): First note that $|G_{i,n}| \leq 2 \zeta_{K,n}^2 \lambda_{K,n}^2$ by the Cauchy-Schwarz inequality and Assumption 2(iii). This, together with Markov’s inequality and Assumption 2(iii) yields

\[
\mathbb{P} \left( \max_{x_n \in S_n} \left| \frac{1}{n} \sum_{i=1}^{n} G_{i,n} \epsilon_{2,i,n} \right| \geq C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right)
\]
\[
\lesssim \frac{\zeta_{K,n} \lambda_{K,n}^2 \mathbb{E} ||| \{ |\epsilon_i| > M_n \} |||}{\zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n}} \leq \frac{\zeta_{K,n} \lambda_{K,n} \sqrt{\mathbb{E} ||| \{ |\epsilon_i| > M_n \} |||}}{M_n^{1+\delta}}
\]
which is $o(1)$ provided $\zeta_{K,n} \lambda_{K,n} \sqrt{n/\log n} = O(M_n^{1+\delta})$. Setting $M_n^{1+\delta} = \zeta_{K,n} \lambda_{K,n} \sqrt{n/\log n}$ trivially satisfies the condition $\zeta_{K,n} \lambda_{K,n} \sqrt{n/\log n} = O(M_n^{1+\delta})$. The condition $M_n = O(\zeta_{K,n}^{-1} \lambda_{K,n}^{-1} \sqrt{n/(\log n)})$ is satisfied for this choice of $M_n$ provided $\zeta_{K,n}^2 \lambda_{K,n}^2 \lesssim (n/\log n)^{\delta/(2+\delta)}$ (cf. condition (i)). Finally, it is straightforward to verify that $M_n \to \infty$ as a consequence of condition (i). Thus, both (51a) and (51b) vanish asymptotically. This completes the proof in the i.i.d. case.

With weakly dependent data we use $\mathbb{P}(A \cap B) \leq \mathbb{P}(A)$ to bound remaining term on the right-hand side of (51) by

\[
\mathbb{P} \left( \left\{ \max_{x_n \in S_n} |h(x_n)| \geq 2C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right\} \right)
\]
\[
\leq \mathbb{P} \left( \max_{x_n \in S_n} \left| \tilde{h}^K(x_n) - \tilde{h}^K(x_n) \right| \geq C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right)
\]
\[
\leq \mathbb{P} \left( \max_{x_n \in S_n} \left| \tilde{h}^K(x_n) \right| \geq C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right)
\]
\[
\leq \mathbb{P} \left( \max_{x_n \in S_n} \left| \tilde{h}^K(x_n) \right| \geq C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right).
\]

It is now shown that a sufficiently large $C$ can be chosen to control terms (58) and (59).
Control of (58): The Cauchy-Schwarz inequality and Assumption 4(iii) yield
\[
\|\tilde{b}^K_w(x_n)\{e/n\} - I_K\{e/n\}\| \leq \zeta_{K,n}\lambda_{K,n}\|(\tilde{b}^K_w - I_K)\| \times O_p(\sqrt{n})
\]
uniformly for \(x_n \in S_n\) (since \(\|\tilde{b}^K_w\| = O_p(\sqrt{n})\) under Assumption 2(i)(ii)). On \(A_n\) we have
\[
\|(\tilde{b}^K_w - I_K)\| = \|(\tilde{b}^K_w - I_K)^{-1}((\tilde{b}^K_w - I_K)\| \leq 2\|(\tilde{b}^K_w - I_K)\|.
\]
Thus \(\tilde{b}^K_w - I_K = O_p(\sqrt{n}/\sqrt{K})\) (i.e. condition (ii)) ensures that (58) can be made arbitrarily small for large enough \(C\).

Control of (59): Let \(M_n\) be as in the i.i.d. case and define
\[
\epsilon_{1,i,n} := \epsilon_i\{|\epsilon_i| \leq M_n\} - E[\epsilon_i\{|\epsilon_i| \leq M_n\}|F_{i-1}]
\]
\[
\epsilon_{2,i,n} := \epsilon_i - \epsilon_{1,i,n}
\]
\[
g_{i,n}(x_n) := \tilde{b}^K_w(x_n)\tilde{b}^K_w(X_i)\{A_n\}.
\]
The relation \(\mathbb{P}(A) \leq \mathbb{P}(A \cap B) + \mathbb{P}(B^c)\) and the triangle inequality together yield
\[
\mathbb{P}\left(\max_{x_n \in S_n} \tilde{b}^K_w(x_n)\tilde{b}^K_w(e/n) \geq C\zeta_{K,n}\lambda_{K,n}\sqrt{(\log n)/n} \right) \leq \mathbb{P}(A_n)
\]
\[
\leq (\#S_n) \max_{x_n \in S_n} \mathbb{P}\left(\left\{\left|\frac{1}{n}\sum_{i=1}^n g_{i,n}\epsilon_{1,i,n}\right| > \frac{C}{2}\zeta_{K,n}\lambda_{K,n}\sqrt{(\log n)/n}\right\} \cap A_n\right)
\]
\[
+ \mathbb{P}\left(\max_{x_n \in S_n} \left|\frac{1}{n}\sum_{i=1}^n g_{i,n}\epsilon_{2,i,n}\right| \geq \frac{C}{2}\zeta_{K,n}\lambda_{K,n}\sqrt{(\log n)/n}\right).
\]

Control of (65a): First note that \(|g_{i,n}| \leq \zeta_{K,n}^2\lambda_{K,n}^2\) by the Cauchy-Schwarz inequality and Assumption 4(iii). This, together with Markov’s inequality and Assumption 2(iii) yields
\[
\mathbb{P}\left(\frac{1}{n}\sum_{i=1}^n g_{i,n}\epsilon_{2,i,n} \geq \frac{C}{2}\zeta_{K,n}\lambda_{K,n}\sqrt{(\log n)/n}\right)
\]
\[
\leq \frac{\zeta_{K,n}^2\lambda_{K,n}^2E[|\epsilon_i|\{||\epsilon_i| > M_n\}] \geq \zeta_{K,n}\lambda_{K,n}\sqrt{n}E[|\epsilon_i|\{||\epsilon_i| > M_n\}] \leq \left(\zeta_{K,n}\lambda_{K,n}\sqrt{(\log n)/n}\right)
\]
which is \(o(1)\) provided \(\zeta_{K,n}\lambda_{K,n}\sqrt{n}/\sqrt{\log n} = O(M_n^{1+\delta})\).

Control of (65a): By Assumption 2(ii), the predictable variation of the summands in (65a) may be
bounded by
\[
\frac{1}{n^2} \sum_{i=1}^{n} E[(g_{i,n}^2) | \mathcal{F}_{i-1}] \lesssim n^{-1} \mathbf{b}_w^K(x_n) \left( \tilde{B}_w^{'n} \tilde{B}_w/n \right) \mathbf{b}_w^K(x_n) \tag{66}
\]

\[
\lesssim \zeta_{K,n}^2 \lambda_{K,n}^2/n \quad \text{on } \mathcal{A}_n \tag{67}
\]

uniformly for \( x_n \in \mathcal{S}_n \). Moreover,
\[
|n^{-1} g_{i,n} \epsilon_{1,i,n}| \lesssim \frac{\zeta_{K,n}^2 \lambda_{K,n}^2 M_n}{n} \tag{68}
\]

uniformly for \( x_n \in \mathcal{S}_n \). An tail bound for martingales (Freedman, 1975, Proposition 2.1) then provides that
\[
(\#\mathcal{S}_n) \max_{x_n \in \mathcal{S}_n} \mathbb{P} \left( \left| \frac{1}{n} \sum_{i=1}^{n} g_{i,n} \epsilon_{1,i,n} \right| > \frac{C}{2} \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n} \right) \cap \mathcal{A}_n
\]
\[
\lesssim n^{\nu_1+\nu_2} \exp \left\{ - \frac{C^2 \zeta_{K,n}^2 \lambda_{K,n}^2 (\log n)/n}{c_1 \zeta_{K,n}^2 \lambda_{K,n}^2/n + c_2 \zeta_{K,n}^2 \lambda_{K,n}^2 M_n/n \times C \zeta_{K,n} \lambda_{K,n} \sqrt{(\log n)/n}} \right\} \tag{69}
\]
\[
\lesssim \exp \left\{ \log n - \frac{C^2 \zeta_{K,n}^2 \lambda_{K,n}^2 (\log n)/n}{c_3 \zeta_{K,n}^2 \lambda_{K,n}^2}/n \right\} + \exp \left\{ \log n - \frac{C \sqrt{n \log n}}{c_4 \zeta_{K,n} \lambda_{K,n}/M_n} \right\} \tag{70}
\]

for finite positive constants \( c_1, \ldots, c_4 \). Thus (65a) vanishes asymptotically for all sufficiently large \( C \) provided \( M_n = O(\zeta_{K,n}^{-1} \lambda_{K,n}^{-1} \sqrt{n/(\log n)}) \). Choosing \( M_n \) as in the i.i.d. case completes the proof. \( \blacksquare \)

**Proof of Remark 2.5** Take any \( h \in L^\infty_{w,n} \) with \( \|h\|_{\infty,w} \neq 0 \). By the Cauchy-Schwarz inequality we have
\[
|P_{K,w,n}(x)| \leq \|\mathbf{b}_w^K(x)\| (\tilde{B}_w^{'n} \tilde{B}_w/n)^{-\tilde{B}_w^{'n} H/n} \tag{71}
\]
\[
\leq \zeta_{K,n} \lambda_{K,n} \| (\tilde{B}_w^{'n} \tilde{B}_w/n)^{-\tilde{B}_w^{'n} H/n} \| \tag{72}
\]

uniformly over \( x \), where \( H = (h(X_1)w_n(X_1), \ldots, h(X_n)w_n(X_n))' \). When \( \lambda_{\min}(\tilde{B}_w^{'n} \tilde{B}_w/n) \geq \frac{1}{2} \) (which it is w.p.1 since \( \|\tilde{B}_w^{'n} \tilde{B}_w/n - I_K\| = o_p(1) \)), we have:
\[
\|(\tilde{B}_w^{'n} \tilde{B}_w/n)^{-\tilde{B}_w^{'n} H/n} \|^2 = (H' \tilde{B}_w/n)(\tilde{B}_w^{'n} \tilde{B}_w/n)^{-1}(\tilde{B}_w^{'n} \tilde{B}_w/n)^{-1} \tilde{B}_w^{'n} H/n \leq 2(H' \tilde{B}_w/n)(\tilde{B}_w^{'n} \tilde{B}_w/n)^{-1} \tilde{B}_w^{'n} H/n \leq 2\|h\|_{w,n}^2 \leq 2\|h\|_{\infty,w}^2
\]
where the second last line is because $\tilde{B}_w (\tilde{B}_w' \tilde{B}_w)^{-1} \tilde{B}_w'$ is a projection matrix. Thus $\|P_{K,w,n} h\|_{\infty, w}/\|h\|_{\infty, w} \leq 2\zeta_{K,n}\lambda_{K,n}$ wpa1 (uniformly in $h$). Taking the sup over $h$ yields the desired result. □

**Proof of Lemma 2.4.** It suffices to control the bias term. Note that $\tilde{h} = P_{K,w,n} h_0$. Therefore, for any $h \in B_{K,w}$ we have, by the usual argument,

$$\|\tilde{h} - h_0\|_{\infty, w} = \|\tilde{h} - h + h - h_0\|_{\infty, w}$$

$$= \|P_{K,w,n} (h_0 - h) + h - h_0\|_{\infty, w} \leq \|P_{K,w,n} (h_0 - h)\|_{\infty, w} + \|h - h_0\|_{\infty, w}$$

$$\leq (1 + \|P_{K,w,n}\|_{\infty, w})\|h_0 - h_0\|_{\infty, w}.$$  

Taking the infimum over $h \in B_{K,w}$ yields the desired result. □

**Proof of Theorem 2.1.** The variance term is $O_p(\sqrt{K(\log n)/n})$ by Lemma 2.3 condition (i) of Lemma 2.3 is satisfied by virtue of the condition $\delta \geq d/p$; condition (ii) is satisfied for $K \asymp (n/\log n)^{d/(2p+d)}$ directly in the i.i.d. case, and by Lemma 2.2 and the conditions on $p$ for the $\beta$-mixing cases.

For the bias term, it is well known that $\inf_{h \in B_{K,w}} \|h_0 - h\|_{\infty, w} = O(K^{-p/d})$ under Assumptions 1, 6 and 7 (e.g. Huang (1998) and Chen (2007)). It therefore remains to show that $\|P_{K,w,n}\|_{\infty, w} \lesssim 1$ wpa1.

When $B_K = \text{BSpl}(K, [0,1]^d, \gamma)$, we may slightly adapt Corollary A.1 of Huang (2003b) to show that $\|P_{K,w,n}\|_{\infty, w} \lesssim 1$ wpa1, using the fact that the empirical and true $L^2(X)$ norms are equivalent over $B_{K,w}$ wpa1 by virtue of the condition $\|\tilde{B}_w \tilde{B}_w/n - I_K\| = o_p(1)$ (see our Lemma 4.1). This condition is satisfied with $K \asymp (n/\log n)^{d/(2p+d)}$ for i.i.d. data (see Lemma 2.1), and is satisfied in the $\beta$-mixing case by Lemma 2.2 and the conditions on $p$.

When $B_K = \text{Wav}(K, [0,1]^d, \gamma)$, the conditions on $K$ in Theorem 5.2 are satisfied with $K \asymp (n/\log n)^{d/(2p+d)}$ under the conditions on $p$ in the Theorem. Therefore, $\|P_{K,w,n}\|_{\infty, w} \lesssim 1$ wpa1. □

**Proof of Lemma 2.5.** By similar arguments to the proof of Lemma 2.3

$$\|\tilde{h} - \tilde{h}\|_{L^2(X)} = \|\tilde{B}_w' \tilde{B}_w/n - \tilde{B}_w' e/n\|_{L^2(X)} \leq \|\tilde{B}_w' \tilde{B}_w/n\| \|\tilde{B}_w' e/n\|.$$  

Chebyshev’s inequality and Assumption 2(i)(ii) yield $\|\tilde{B}_w' e/n\| = O_p(\sqrt{K/n})$. Moreover, it follows from Assumption 5 that $\|\tilde{B}_w' \tilde{B}_w/n\| = O_p(1)$.

For the remaining term it suffices to show that $\|\tilde{h} - h_0\|_{L^2(X)} = O_p(\|h_0 - h_{0,K}\|_{L^2(X)})$. By the
triangle inequality we bound

\[ \|\tilde{h} - h_0\|_{L^2(X)} \leq \|\tilde{h} - h_{0,K}\|_{L^2(X)} + \|h_{0,K} - h_0\|_{L^2(X)}. \]  

(78)

Recall the definition of the empirical projection \( P_{K,w,n} \) from expression (15), and observe that \( \tilde{h} = P_{K,w,n}h_0 \) and that \( P_{K,w,n}h = h \) for all \( h \in B_{K,w} \). Also recall the definition of \( L^2_{w,n}(X) \) as the space of functions with finite norm \( \| \cdot \|_{w,n} \) where \( \|f\|_{w,n}^2 = \frac{1}{n} \sum_{i=1}^{n} f(X_i)^2 w_n(X_i) \). Since the empirical and theoretical \( L^2(X) \) norms are equivalent over \( B_{K,w} \), see Section 4.2. Therefore, we have

\[ \|\tilde{h} - h_{0,K}\|_{L^2(X)} = \|P_{K,w,n}(h_0 - h_{0,K})\|_{L^2(X)} \]  

(79)

\[ \times \|P_{K,w,n}(h_0 - h_{0,K})\|_{w,n} \) wpa1 \]  

(80)

\[ \leq \|P_{K,w,n}(h_0 - h_{0,K})\|_{w,n} \]  

(81)

where the second line is by equivalence of the empirical and theoretical \( L^2(X) \) norms wpa1, and the final line is because \( P_{K,w,n} \) is an orthogonal projection on \( L^2_{w,n}(X) \). Finally, Markov’s inequality yields

\[ \|P_{K,w,n}(h_0 - h_{0,K})\|_{w,n}^2 = O_p(\|h_0 - h_{0,K}\|_{L^2(X)}^2). \]  

7.2 Proofs for Section 3

Proof of Lemma 3.1. We use a truncation argument together with exponential inequalities for random matrices. Let \( M_n \approx (\zeta_{K,n}\lambda_{K,n})^{(2+\delta)/\delta} \) (with \( \delta \) as in Assumption 2(iii)) be a sequence of positive numbers and let

\[ \tilde{\Omega}_1 = \frac{1}{n} \sum_{i=1}^{n} (\Xi_{1,i} - E[\Xi_{1,i}]) \]  

(82)

\[ \tilde{\Omega}_2 = \frac{1}{n} \sum_{i=1}^{n} (\Xi_{2,i} - E[\Xi_{2,i}]) \]  

(83)

\[ \Xi_{1,i} = \epsilon_i^T \tilde{b}_w^K(X_i) \tilde{b}_w^K(X_i)' \{\epsilon_i^T \tilde{b}_w^K(X_i) \tilde{b}_w^K(X_i)\} \leq M_n^2 \} \]  

(84)

\[ \Xi_{2,i} = \epsilon_i^T \tilde{b}_w^K(X_i) \tilde{b}_w^K(X_i)' \{\epsilon_i^T \tilde{b}_w^K(X_i) \tilde{b}_w^K(X_i)\} > M_n^2 \} \]  

(85)

Clearly \( \tilde{\Omega} = \tilde{\Omega}_1 + \tilde{\Omega}_2 \), so it is enough to show that \( \|\tilde{\Omega}_1\| = o_p(1) \) and \( \|\tilde{\Omega}_2\| = o_p(1) \).

Control of \( \|\tilde{\Omega}_1\| \): By definition, \( \|\Xi_{1,i}\| \leq M_n^2 \). It follows by the triangle inequality and Jensen’s
inequality (\(\|\cdot\|\) is convex) that \(\|\Xi_{1,i} - E[\Xi_{1,i}]\| \leq 2M_n\). Moreover, by Assumption 2(ii)

\[
E[(\Xi_{1,i} - E[\Xi_{1,i}])^2] \leq E[\epsilon_i^2 \|\hat{b}^K_{w}(X_i)\|^2 \hat{b}^K_{w}(X_i) \hat{b}^K_{w}(X_i)'] \{\|\epsilon_i^2 \hat{b}^K_{w}(X_i) \hat{b}^K_{w}(X_i)\| \leq M_n^2\} \quad (86)
\]

\[
\leq M_n^2 E[\epsilon_i^2 \|\hat{b}^K_{w}(X_i)\|^2 \hat{b}^K_{w}(X_i) \hat{b}^K_{w}(X_i)'] \quad (87)
\]

\[
\leq M_n^2 E[\epsilon_i^2 |X_i| \hat{b}^K_{w}(X_i) \hat{b}^K_{w}(X_i)'] \quad (88)
\]

\[
\leq M_n^2 E[\hat{b}^K_{w}(X_i) \hat{b}^K_{w}(X_i)'] = M_n^2 \hat{I}_K \quad (89)
\]

where the inequalities are understood in the sense of positive semi-definite matrices. It follows that \(\|E[(\Xi_{1,i} - E[\Xi_{1,i}])^2]\| \approx M_n^2\). In the i.i.d. case, Corollary 111 yields \(\|\hat{\Omega}_1\| = O_p(M_n \sqrt{\log K}/n) = o_p(1)\).

In the \(\beta\)-mixing case, Corollary 112 yields \(\|\hat{\Omega}_1\| = O_p(M_n \sqrt{q \log K}/n)\), and the result follows by taking \(q = \gamma^{-1} \log n\) in the exponentially \(\beta\)-mixing case and \(q \asymp n^{1/(1+\gamma)}\) in the algebraically \(\beta\)-mixing case.

Control of \(\|\hat{\Omega}_2\|\): The simple bound \(\|\Xi_{2,i}\| \leq (\zeta_{K,n} \lambda_{K,n})^2 \epsilon_i^2 \{\epsilon_i^2 > M_n^2/(\zeta_{K,n} \lambda_{K,n})^2\}\) together with the triangle inequality and Jensen’s inequality (\(\|\cdot\|\) is convex) yield

\[
E[\|\hat{\Omega}_2\|] \leq 2(\zeta_{K,n} \lambda_{K,n})^2 E[\epsilon_i^2 \{\epsilon_i > M_n/(\zeta_{K,n} \lambda_{K,n})\}] \quad (90)
\]

\[
\leq 2(\zeta_{K,n} \lambda_{K,n})^{2+\delta} M_n^2 E[\epsilon_i^2 \{\epsilon_i > M_n/(\zeta_{K,n} \lambda_{K,n})\}] = o(1) \quad (91)
\]

by Assumption 2(iii) because \(M_n/(\zeta_{K,n} \lambda_{K,n}) \propto (\zeta_{K,n} \lambda_{K,n})^{-2/\delta} \to \infty\) and \((\zeta_{K,n} \lambda_{K,n})^{-2+\delta}/M_n^2 \propto 1\).

Therefore, \(\|\hat{\Omega}_2\| = o_p(1)\) by Markov’s inequality.

**Proof of Theorem 3.1.** First define \(u^*_K(x) = v^*_K(x)/\|v^*_K\|_{sd}\). Note that \(E[(u^*_K(X_i)\epsilon_i)] = 1\),

\(E[u^*_K(X_i)^2] = \|v^*_K\|_{L^2(X)}/\|v\|_{sd} \asymp 1\) (by Assumptions 2(ii)(iv)), and \(\|u^*_K\|_{\infty} \lesssim \zeta_{K,n} \lambda_{K,n}\).

By Assumption 9(i)(ii) and the fact that \(\hat{h}, \tilde{h} \in N_{K,n}\) wpa1, we obtain:

\[
\frac{\sqrt{n}(f(\hat{h}) - f(\tilde{h}))}{V_K^{1/2}} = \frac{\sqrt{n} \frac{\partial f(h_0)}{\partial h} [\hat{h} - \tilde{h}]}{V_K^{1/2}} + o_p(1) \quad (92)
\]

\[
= \frac{1}{\sqrt{n}} \sum_{i=1}^{n} u^*_K(X_i)\epsilon_i + \frac{\partial f(h_0)}{\partial h} [\tilde{b}^K_{w}']((\hat{B}'_w \hat{B}_w/n) - I_K)(\hat{B}'_w e/\sqrt{n}) + o_p(1) \quad (93)
\]

The leading term is now shown to be asymptotically \(N(0,1)\) and the second term is shown to be asymptotically negligible. The proof of this differs depending upon whether the data are i.i.d. or weakly dependent.
With i.i.d. data, we first show that the second term on the right-hand side of (93) is $o_p(1)$. Let $\eta > 0$ be arbitrary. Let $C_\eta$ be such that $\limsup \mathbb{P}(\|\tilde{B}_w^t \tilde{B}_w^t / n - I_K\| > C_\eta \zeta_{K,n} \lambda_{K,n} \sqrt{\log K}/n) \leq \eta$ (we may always choose such a $C_\eta$ by Lemma 2.1), let $C_{n,\eta}$ denote the event $\|\tilde{B}_w^t \tilde{B}_w^t / n - I_K\| \leq C_\eta \zeta_{K,n} \lambda_{K,n} \sqrt{\log K}/n$ and let $\{C_{n,\eta}\}$ denote its indicator function. Observe that $V_K^{1/2} \geq \|\tilde{f}(h)\tilde{g}_w\|$ (under Assumption 2(ii)(iv)). Let $E[|X_i|^{n}]$ denote expectation conditional on $X_1, \ldots, X_n$ and let $\tilde{b}_w^K$ denote $\frac{\partial \tilde{f}(h_\eta)\tilde{g}_w}{\partial h}$ By iterated expectations,

$$
E \left[ \left( \frac{(\tilde{b}_w^K)'((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)(\tilde{B}_w^t e / \sqrt{n})}{V_K^{1/2}} \right)^2 \{C_{n,\eta}\} \right]
= \frac{(\tilde{b}_w^K)'E[((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)(\frac{1}{n} \sum_i E[\epsilon_i^2 \tilde{b}_w^K(X_i)\tilde{g}_w(X_i)']((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)\{C_{n,\eta}\}]\tilde{b}_w^K}{V_K}
= \frac{(\tilde{b}_w^K)'E[((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)(\frac{1}{n} \sum_i E[\epsilon_i^2 \tilde{b}_w^K(X_i)\tilde{g}_w(X_i)']((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)\{C_{n,\eta}\}]\tilde{b}_w^K}{V_K}
\leq \frac{(\tilde{b}_w^K)'E[((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)(\tilde{B}_w^t \tilde{B}_w^t / n)((\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K)\{C_{n,\eta}\}]\tilde{b}_w^K}{V_K}
\leq C_\eta^2 \zeta_{K,n}^2 \lambda_{K,n}^2 (\log K)/n = o(1)
$$

(94)

for all $n$ sufficiently large, where the second last line is by Assumption 2(ii) and the final line is because both $\|(\tilde{B}_w^t \tilde{B}_w^t / n)^{-} - I_K\| \leq \|(\tilde{B}_w^t \tilde{B}_w^t / n) - I_K\|$ and $\|(\tilde{B}_w^t \tilde{B}_w^t / n)\| \leq 1$ hold on $C_{n,\eta}$ for all $n$ sufficiently large under Assumption 5. As $\liminf \mathbb{P}(C_{n,\eta}) \geq 1 - \eta$ and $\eta$ is arbitrary, the second term in (93) is therefore $o_p(1)$.

Now consider the leading term in (93). The summands are i.i.d. with mean zero and unit variance. The Lindeberg condition is easily verified:

$$
E[\epsilon_i^2 u_K^*(X_i)^2 | \epsilon_i u_K^*(X_i) > \eta \sqrt{n}] = E[\epsilon_i^2 u_K^*(X_i)^2 | \epsilon_i > \eta (\sqrt{n}/\zeta_{K,n}\lambda_{K,n})] 
\leq \sup_{x} E[\epsilon_i^2 | \epsilon_i > \eta (\sqrt{n}/\zeta_{K,n}\lambda_{K,n}) | X_i = x] = o(1)
$$

(95) (96)

by Assumption 2(v) because $\zeta_{K,n}^2 \lambda_{K,n}^2 / n = o(1)$. Thus the leading term is asymptotically $N(0, 1)$ by the Lindeberg-Feller theorem.

With weakly dependent data we apply the Cauchy-Schwarz inequality to the second term in
expression (93) to obtain

\[
\left| \frac{\partial f(h_0)}{\partial h} \left[ \tilde{b}_K^n \right] \left( (\tilde{B}_w \tilde{B}_w/n)^- - I_K \right) (\tilde{B}_w e/\sqrt{n}) \right| V_K^{1/2} \\
\leq \left| \frac{\partial f(h_0)}{\partial h} \left[ \tilde{b}_K^n \right] \right| \left\| (\tilde{B}_w \tilde{B}_w/n)^- - I_K \right\| \left\| \tilde{B}_w e/\sqrt{n} \right\| \times \sqrt{n}
\]

(97)

wpa1, because \( \left| \frac{\partial f(h_0)}{\partial h} \left[ \tilde{b}_K^n \right] \right| \propto V_K^{1/2} \) and \( \left\| (\tilde{B}_w \tilde{B}_w/n)^- - I_K \right\| \leq 2 \left\| (\tilde{B}_w \tilde{B}_w/n) - I_K \right\| \) wpa1 by Assumption 5. Assumption 2(i)(ii) implies \( \left\| \tilde{B}_w e/n \right\| = O_p(\sqrt{K/n}) \), whence the second term in expression (93) is \( o_p(1) \) by the condition \( \left\| (\tilde{B}_w \tilde{B}_w/n) - I_K \right\| = o_p(K^{-1/2}) \).

To show the leading term in (93) is asymptotically \( N(0,1) \) we use a martingale CLT (Corollary 2.8 of McLeish (1974)). This verifying the conditions (a) \( \max_{i \leq n} |u^*_K(X_i) \varepsilon_i/\sqrt{n}| \rightarrow_p 0 \) and (b) \( \frac{1}{n} \sum_{i=1}^n u^*_K(X_i) \varepsilon_i^2 \rightarrow_p 0 \). To verify condition (a), let \( \eta > 0 \) be arbitrary. Then,

\[
P(\max_{i \leq n} |\varepsilon_i u^*_K(X_i)/\sqrt{n}| > \eta) \leq \sum_{i=1}^n P(|\varepsilon_i u^*_K(X_i)/\sqrt{n}| > \eta) \leq \frac{1}{n\eta^2} \sum_{i=1}^n E[\varepsilon_i^2 u^*_K(X_i)^2 \{|\varepsilon_i u^*_K(X_i)/\sqrt{n}| > \eta\}] = \frac{1}{n\eta^2} E[\varepsilon_i^2 u^*_K(X_i)^2 \{|\varepsilon_i u^*_K(X_i)/\sqrt{n}| > \eta\}]
\]

(101)

which again is \( o(1) \) by Assumption 2(v) since \( \zeta^2_{K,n} \lambda^2_{K,n} \rightarrow 0 \). For condition (b), note that \( \left\| \frac{\partial f(h_0)}{\partial h} \left[ \tilde{b}_K^n \right] / \left\| v^*_K \right\|_{sd} \right\| = \left\| v^*_K \right\|_{L^2(X)} / \left\| v^*_K \right\|_{sd} \approx 1 \). Then by the Cauchy-Schwarz inequality, we have

\[
\left| \frac{1}{n} \sum_{i=1}^n u^*_K(X_i) \varepsilon_i^2 - 1 \right| = \left| \left( \frac{\partial f(h_0)}{\partial h} \left[ \tilde{b}_K^n \right] / \left\| v^*_K \right\|_{sd} \right) \right| (\Omega - \Omega) \left( \frac{\partial f(h_0)}{\partial h} \left[ \tilde{b}_K^n \right] / \left\| v^*_K \right\|_{sd} \right) \leq \left| \tilde{\Omega} - \Omega \right|
\]

(103)

which is \( o_p(1) \) by Assumption 8. Therefore, the leading term in (93) is asymptotically \( N(0,1) \).

It remains to show that

\[
\frac{\sqrt{n}(f(\tilde{h}) - f(h_0))}{V_K^{1/2}} = o_p(1).
\]

(104)

Assumption 9(ii) and the fact that \( \tilde{h} \in N_{K,n} \) wpa1 together yield

\[
\frac{\sqrt{n}(f(\tilde{h}) - f(h_0))}{V_K^{1/2}} = \sqrt{\frac{n}{V_K} \frac{\partial f(h_0)}{\partial h} (\tilde{h} - h_0) + o_p(1)}.
\]

(105)
which is $o_p(1)$ by Assumption 9(iii).

**Proof of Corollary 3.1.** The result follows from Theorem 3.1. Assumption 9(iii) is satisfied for these bases under Assumptions 1 and 7. Moreover, Assumption 5 is satisfied under the restrictions on $K$ (see Lemmas 2.1 and 2.2). Assumption 9 is satisfied provided $\sqrt{n}||\overline{h} - h_0||_\infty = o(V_K^{-1/2})$. But $||\overline{h} - h_0||_\infty = O_p(K^{-p/d})$ by the proof of Theorem 2.1 so $\sqrt{n}V_K^{-1/2}K^{-p/d} = o(1)$ is sufficient for Assumption 9 to hold. Moreover, under Assumption 2(iii), Lemma 3.1 shows that Assumption 8 and the condition $||\overline{B}_w^tB_w/n-I_K|| = o_p(K^{-1/2})$ are satisfied for weakly dependent data under the respective conditions on $K$ (see Lemma 2.2).

**Proof of Corollary 3.2.** The result follows by Theorem 3.1 with Assumption 9(i')–(iv') in place of Assumption 9 (see Remark 3.1). Most conditions of Theorem 3.1 can be verified in the same way as those for Corollary 3.1. Assumption 9(iv') is satisfied under the conditions on $K$ because $||\overline{h} - h_0||_\infty = O_p(K^{-p/d})$ by the proof of Theorem 2.1 and $||\overline{h} - \bar{h}||_\infty = O_p(\sqrt{(K \log n)/n})$ by Lemma 2.3.

**Proof of Lemma 3.2.** Result (2) follows from Theorem 3.1 and Result (1) of Lemma 3.2 by the continuous mapping theorem. It remains to show Result (1). By addition and subtraction of terms,

$$
\frac{||v^*_K||^2_{sd}}{||v^*_K||^2_{sd}} = \frac{1}{n} \sum_{i=1}^{n} \epsilon_i^2 v^*_K(X_i)^2 + \frac{1}{n} \sum_{i=1}^{n} \epsilon_i^2 (\tilde{v}^*_K(X_i)^2 - v^*_K(X_i)^2) + \frac{1}{n} \sum_{i=1}^{n} (\tilde{h}(X_i) - h_0(X_i))^2 v^*_K(X_i)^2 - \frac{1}{n} \sum_{i=1}^{n} (\tilde{h}(X_i) - h_0(X_i))^2 (\tilde{v}^*_K(X_i)^2 - v^*_K(X_i)^2) \tag{106}
$$

$$
- \frac{2}{n} \sum_{i=1}^{n} \epsilon_i (\tilde{h}(X_i) - h_0(X_i))v^*_K(X_i)^2 - \frac{2}{n} \sum_{i=1}^{n} \epsilon_i (\tilde{h}(X_i) - h_0(X_i))(\tilde{v}^*_K(X_i)^2 - v^*_K(X_i)^2)
$$

$$
=: T_1 + T_2 + T_3 + T_4 + T_5 + T_6.
$$

Control of $T_1$: $T_1 \rightarrow_p 1$ by Assumption 8

Control of $T_2$: Let

$$
\partial = \frac{\partial f(h_0)}{\partial v^*_K} \tag{107}
$$

$$
\hat{\partial} = \frac{\partial f(\tilde{h})}{\partial v^*_K} \tag{108}
$$

$$
\tilde{\partial} = (\tilde{B}_w^t\tilde{B}_w/n)^{-1}\hat{\partial}. \tag{109}
$$
Then with this notation,

\[ |T_2| = |(\hat{\partial} + \partial)'\hat{\Omega} - \partial'\hat{\Omega}\partial| \leq \|\hat{\Omega}\|\|\hat{\partial} - \partial\| \leq \|\hat{\partial} + \partial'\|\|\hat{\Omega}\|\|(\hat{\partial} - \partial)\|. \] (110)

Note that \(\|\hat{\Omega}\| = O_p(1)\) by Assumption 3(iii). By the triangle inequality and definition of \(\partial, \hat{\partial},\) and \(\hat{\partial},\)

\[ \|\hat{\partial} - \hat{\partial}\| \leq \|(\hat{B}_w'\hat{B}_w/n) - I_K\|\|\hat{\partial} - \partial\| + \|\partial\|. \] (111)

Assumption 5 implies \(\|(\hat{B}_w'\hat{B}_w/n) - I_K\| = o_p(1)\); \(\|\hat{\partial} - \partial\| = o_p(1)\) by Assumption 2(iv), because \(\hat{h} \in N_{K,n}\) wpa1; and \(\|\partial\| \times 1 \) because \(\|v^*_K\|_{L^2(X)} \times v^*_K\|_{sd}\) under Assumption 2(ii)(iv). Therefore, \(\|\hat{\partial} - \hat{\partial}\| = o_p(1)\); \(\|\hat{\partial} + \hat{\partial}\| = O_p(1)\), and so \(T_2 = o_p(1)\).

Control of \(T_3\): First note that

\[ |T_3| \leq \|\hat{h} - h_0\|_{\infty,w}^2 \times \frac{1}{n} \sum_{i=1}^{n} \frac{v_K(X_i)^2}{\|v^*_K\|_{sd}^2} = o_p(1) \times O_p(1) = o_p(1) \] (112)

where \(\|\hat{h} - h_0\|_{\infty,w} = o_p(1)\) by hypothesis and \(n^{-1} \sum_{i=1}^{n} v_K(X_i)^2/\|v^*_K\|_{sd}^2\) by Markov’s inequality and the fact that \(\|v^*_K\|_{L^2(X)} \times \|v^*_K\|_{sd}\) under Assumption 2(ii)(iv).

Control of \(T_4\): by the triangle inequality definition of \(\hat{v}_K^*\) and \(v^*_K\):

\[ |T_4| \leq \|\hat{h} - h_0\|_{\infty,w}^2 \times \left( \frac{1}{n} \sum_{i=1}^{n} \frac{\hat{v}_K^*(X_i)^2}{\|v^*_K\|_{sd}^2} + \sum_{i=1}^{n} \frac{v_K(X_i)^2}{\|v^*_K\|_{sd}^2} \right) \] (113)

\[ = o_p(1) \times \left( \|\hat{\Omega}\| \times \left( \|\hat{\partial}\|^2 + \|\partial\|^2 \right) \right) \] (114)

Moreover, \(\|\hat{\Omega}\| = O_p(1)\) by Assumption 8, \(\|\partial\| \times 1 \) by Assumption 2(ii)(iv), and \(\|\hat{\partial}\| \leq \|\hat{\partial} - \hat{\partial}\| + \|\hat{\partial} - \hat{\partial}\| + \|\partial\| = O_p(1)\) by Assumption 5 and 9(iv). It follows that \(|T_4| = o_p(1)\).

Control of \(T_5\): By the inequality \(2|a| \leq 1 + a^2\), we have

\[ |T_5| \leq \|\hat{h} - h_0\|_{\infty,w} \times \frac{\sum_{i=1}^{n} (1 + \epsilon_i v^*_K(X_i)^2)}{\|v^*_K\|_{sd}^2} = o_p(1) \times O_p(1) = o_p(1) \] (115)

where \(\|\hat{h} - h_0\|_{\infty,w} = o_p(1)\) by hypothesis, \(n^{-1} \sum_{i=1}^{n} \epsilon_i^2 v^*_K(X_i)^2/\|v^*_K\|_{sd}^2 \to p 1\) by Assumption 8 and the remaining term is \(O_p(1)\) by the arguments for \(T_3\).

Control of \(T_6\): The proof is essentially the same as that for \(T_2\), except we replace \(\hat{\Omega}\) by the matrix
\[ \hat{\Omega} = n^{-1} \sum_{i=1}^{n} \epsilon_i (\hat{\mu}(X_i) - \mu_0(X_i)) \tilde{b}_w^K(X_i) \tilde{b}_w^K(X_i)' . \]
By the inequality \(2|a| \leq 1 + a^2\), it follows that

\[
\|\hat{\Omega}\| \leq \|\hat{\mu} - \mu_0\|_{\infty,w} \times \left\| n^{-1} \sum_{i=1}^{n} (1 + \epsilon_i^2) \tilde{b}_w^K(X_i) \tilde{b}_w^K(X_i)' \right\| \tag{116}
\]

because \(\|\hat{\mu} - \mu_0\|_{\infty,w} = o_p(1), \|\tilde{B}_w'B_w/n + \hat{\Omega}\| = o_p(1) \times o_p(1) = o_p(1)\) by Assumption 5, and \(\|\hat{\Omega}\| = O_p(1)\) by Assumption 8.

**Proof of Theorem 3.2.** This follows from Lemma 3.2.

First, Assumption 5 is satisfied for i.i.d. and \(\beta\)-mixing data under the respective conditions on \(K\) (see Lemmas 2.1 and 2.2). Moreover, Lemma 3.1 shows that Assumption 8 and the condition \(\|\tilde{B}_w'B_w/n - I_K\| = o_p(K^{-1/2})\) is satisfied for weakly dependent data under the respective conditions on \(K\) (see Lemma 2.2). Therefore Theorem 3.1 may be applied for asymptotic normality of \(f(\hat{\mu})\).

To apply Lemma 3.2 it remains to show that \(\|\hat{\mu} - \mu_0\|_{\infty,w} = o_p(1)\). But \(\|\hat{\mu} - \mu_0\|_{\infty} = o_p(1)\) by assumption, and \(\|\hat{\mu} - \hat{\mu}\|_{\infty} = O_p(\zeta_K,n\lambda_K,n\sqrt{(\log n)/n}) = o_p(1)\) by Lemmas 2.3, 2.1 and 2.2 under the conditions on \(K\).

**7.3 Proofs for Section 4**

**Proof of Corollary 4.1.** Follows from Theorem 4.1 with \(t = C\sigma_n / \sqrt{\log(d_1 + d_2)}\) for sufficiently large \(C\), and applying the condition \(R_n \sqrt{\log(d_1 + d_2)} = o(\sigma_n)\).

**Proof of Theorem 4.2.** By Berbee’s lemma (enlarging the probability space as necessary) the process \(\{X_i\}\) can be coupled with a process \(X_i^*\) such that \(Y_k := \{X_{(k-1)q+1}, \ldots, X_{kq}\}\) and \(Y_k^* := \{X_{(k-1)q+1}^*, \ldots, X_{kq}^*\}\) are identically distributed for each \(k \geq 1\), \(P(Y_k \neq Y_k^*) \leq \beta(q)\) for each \(k \geq 1\) and \(\{Y_1^*, Y_3^*, \ldots\}\) are independent and \(\{Y_2^*, Y_4^*, \ldots\}\) are independent (see Lemma 2.1 of Berbee (1987)).

Let \(I_e\) and \(I_o\) denote the indices of \(\{1, \ldots, n\}\) corresponding to the odd- and even-numbered blocks, and \(I_r\) the indices in the remainder, so \(I_r = q[n/q] + 1, \ldots, n\) when \(q[n/q] < n\) and \(I_r = \emptyset\) when \(q[n/q] = n\).
Let \( \Xi_{i,n}^* = \Xi(X_{i,n}^*) \). By the triangle inequality,

\[
\mathbb{P} \left( \| \sum_{i=1}^n \Xi_{i,n} \| \geq 6t \right)
\leq \mathbb{P} \left( \| \frac{n}{q} \Xi_{i,n}^* \| + \| \sum_{i \in I_c} \Xi_{i,n} \| + \| \sum_{i \notin I_c} \Xi_{i,n}^* \| - \Xi_{i,n} \| \geq 6t \right)
\leq \frac{n}{q} \beta(q) + \mathbb{P} \left( \| \sum_{i \in I_c} \Xi_{i,n}^* \| \geq t \right) + \mathbb{P} \left( \| \sum_{i \notin I_c} \Xi_{i,n}^* \| \geq t \right)
\]

To control the last two terms we apply Theorem 4.1 recognizing that \( \sum_{i \in I_c} \Xi_{i,n}^* \) and \( \sum_{i \notin I_c} \Xi_{i,n}^* \) are each the sum of fewer than \( \lfloor n/q \rfloor \) independent \( d_1 \times d_2 \) matrices, namely \( W_i^* = \sum_{i=(k-1)q+1}^{kq} \Xi_{i,n}^* \). Moreover each \( W_i^* \) satisfies \( \| W_i^* \| \leq qR_n \) and \( \max\{\|E[W_i^*W_i^*']\|, \|E[W_i'^*W_i^*]\|\} \leq q^2 s_n \). Theorem 4.1 then yields

\[
\mathbb{P} \left( \| \sum_{i \in I_c} \Xi_{i,n}^* \| \geq t \right) \leq (d_1 + d_2) \exp \left( -\frac{t^2/2}{nqs_n^2 + qR_n t/3} \right)
\]

and similarly for \( I_o \). ■

**Proof of Corollary 4.2** Follows from Theorem 4.2 with \( t = Cs_n \sqrt{nq \log(d_1 + d_2)} \) for sufficiently large \( C \), and the conditions \( \frac{n}{q} \beta(q) = o(1) \) and \( R_n \sqrt{q \log(d_1 + d_2)} = o(s_n \sqrt{n}) \). ■

**Proof of Lemma 4.1** Let \( G = E[b^K_w(X_i)b^K_w(X_i')] \). Since \( B_{K,w} = \text{clsp}\{b_{K1}w_n, \ldots, b_{KK}w_n\} \), we have:

\[
\sup\{\frac{1}{n} \sum_{i=1}^n b(X_i)^2 - 1 : b \in B_{K,w}, E[b(X)^2] = 1\}
= \sup\{\|c'(B_w' B_w/n - G)c\| : c \in \mathbb{R}^K, \|G^{1/2} c\| = 1\}
= \sup\{\|c'G^{1/2}(G^{-1/2}(B_w' B_w/n)G^{-1/2} - I_K)G^{1/2} c\| : c \in \mathbb{R}^K, \|G^{1/2} c\| = 1\}
= \sup\{\|c'(\tilde{B}_w' \tilde{B}_w/n - I_K)c\| : c \in \mathbb{R}^K, \|c\| = 1\}
= \|\tilde{B}_w' \tilde{B}_w/n - I_K\|_2^2
\]

as required. ■

### 7.4 Proofs for Section 5

We first present a general result that allows us to bound the \( L^\infty \) operator norm of the \( L^2(X) \) projection \( P_K \) onto a linear sieve space \( B_K \equiv \text{clsp}\{b_{K1}, \ldots, b_{KK}\} \) by the \( \ell^\infty \) norm of the inverse of its corresponding Gram matrix.

**Lemma 7.1** If there exists a sequence of positive constants \( \{c_K\} \) such that (i) \( \sup_{x \in X} \|b^K(x)\|_\ell^1 \lesssim c_K \)
and (ii) \( \max_{1 \leq k \leq K} \| b_{Kk} \|_{L^1(\Omega)} \leq c_K^{-1} \), then

\[
\| P_K \|_\infty \lesssim \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} \|_{\ell^\infty}.
\]

**Proof of Lemma 7.2.** By Hölder's inequality (with (i)), definition of the operator norm, and Hölder's inequality again (with (ii)), we obtain:

\[
| P_K f(x) | = | b^{K}(x) (E[b^{K}(X_i)]b^{K}(X_i))^{-1} E[b^{K}(X_i)] f(X_i) | \\
\leq \| b^{K}(x) \|_{\ell^1} \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} E[b^{K}(X_i)] f(X_i) \|_{\ell^\infty} \\
\leq c_K \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} \|_{\ell^\infty} \| E[b^{K}(X_i)] f(X_i) \|_{\ell^\infty} \\
\leq c_K \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} \|_{\ell^\infty} \max_{1 \leq k \leq K} E[|b_{Kk}(X_i)|f(X_i)] \\
\leq c_K \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} \|_{\ell^\infty} \max_{1 \leq k \leq K} E[|b_{Kk}(X_i)|] \| f \|_\infty \\
\lesssim \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} \|_{\ell^\infty} \| f \|_\infty
\]

uniformly in \( x \). The result now follows by taking the supremum over \( x \in \mathcal{X} \). \( \blacksquare \)

We will bound \( \| (E[b^{K}(X_i)]b^{K}(X_i))^{-1} \|_{\ell^\infty} \) for (tensor product) wavelet bases using the following Lemma.

**Lemma 7.2** Let \( A \in \mathbb{R}^{K \times K} \) be a positive definite symmetric matrix such that \( A_{i,j} = 0 \) whenever \( |i - j| > m/2 \) for \( m \) even. Then: \( \| A^{-1} \|_{\ell^\infty} \leq \frac{2C}{\kappa} \) where

\[
\kappa = \lambda_{\max}(A)/\lambda_{\min}(A) \\
\lambda = \left( \frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2/m} < 1 \\
C = \| A^{-1} \| \max\{1, (1 + \sqrt{\kappa})^2/(2\kappa)\}.
\]

**Proof of Lemma 7.2.** By definition of the matrix infinity norm, we have

\[
\| A^{-1} \|_\infty = \max_{j \leq K} \sum_{k=1}^{K} |(A^{-1})_{j,k}|.
\]
The result now follows by Theorem 2.4 of Demko, Moss, and Smith (1984) (which states that $|(A^{-1})_{i,j}| \leq C\lambda^{i-j}$ for all $i,j$) and geometric summation.

**Proof of Theorem 5.1.** We first prove the univariate case (i.e. $d = 1$) before generalizing to the multivariate case.

By the definition of wavelet basis, we may assume without loss of generality that $b_{K1} = \varphi, b_{K2} = \varphi_{1,2} \ldots$.

For any $x \in [0, 1]$ the vector $b^K(x)$ has, at most, $2N$ elements that are nonzero (as a consequence of the compact support of the $\varphi_{1,k}$). It follows that

$$
\|b^K(x)\|_1 \leq (2N)2^{J/2} \max\{\|\varphi\|_\infty, \|\varphi_J\|_\infty, \ldots, \|\varphi_{J-1}\|_\infty, \|\varphi_{J+1}\|_\infty, \ldots, \|\varphi_{N}\|_\infty\} \lesssim 2^{J/2}
$$

uniformly in $x$. Therefore $\sup_{x \in [0,1]} \|b^K(x)\|_1 \lesssim \sqrt{K}$. Let $k$ be such that $N \leq k \leq 2^J - N - 1$. By boundedness of $f_X$ and a change of variables, we have (with $\mu$ denoting Lebesgue measure)

$$
E[|\varphi_{1,k}(X_i)|] \leq \sup_{x \in [0,1]} f_X(x) \int_{\mathbb{R}} 2^{J/2} |\varphi(2^J x - k)| \, d\mu(x) \leq \sup_{x \in [0,1]} f_X(x) 2^{-J/2} \int_{\mathbb{R}} |\varphi(y)| \, d\mu(y) \leq \sup_{x \in [0,1]} f_X(x) 2^{-J/2} \|\varphi\|_{L^1(\mu)}
$$

where $\|\varphi\|_{L^1(\mu)} < \infty$ because $\varphi$ has compact support and is continuous. Similar arguments can be used to show the same for the $N$ left and right scaling functions. It follows that $\max_k \|b_{Nk}\|_{L^1(X)} \lesssim 2^{-J/2} = K^{-1/2}$. Therefore, the $b_{K1}, \ldots, b_{KK}$ satisfy the conditions of Lemma 7.1 and hence $P_K \|_{\infty} \lesssim \| (E[b^K(X_i)b^K(X_j)])^{-1} \|_{\infty}$. It remains to prove that $\| (E[b^K(X_i)b^K(X_j)])^{-1} \|_{\infty} \lesssim 1$. We first verify the conditions of Lemma 7.2. Disjoint support of the $\varphi_{1,k}$ implies that $(E[b^K(X_i)b^K(X_j)])_{k,j} = 0$ whenever $|k - j| > 2N - 1$.

For positive definiteness, we note that

$$
\lambda_{\max}(E[b^K(X_i)b^K(X_j)]) \leq \left( \sup_{x \in [0,1]} f_X(x) \right) \lambda_{\max} \left( \int_{[0,1]} b^K(x)b^K(x) \, d\mu(x) \right) \left( \sup_{x \in [0,1]} f_X(x) \right) \geq \lambda_{\min}(E[b^K(X)b^K(X)]) \geq 0
$$

(where we understand the integral performed element wise) because $\varphi, \varphi_{1,0}, \ldots, \varphi_{1,2^J-1}$ are an orthonormal basis for $V_J$ with respect to the $L^2([0,1])$ inner product. Similarly, $\lambda_{\min}(E[b^K(X)b^K(X)]) \geq \lambda_{\min}(E[b^K(X)b^K(X)]) \geq 0$.
\[ \inf_{x \in [0,1]} f_X(x) \]. Therefore

\[ \kappa \leq (\sup_{x \in [0,1]} f_X(x))/(\inf_{x \in [0,1]} f_X(x)) < \infty \]

uniformly in \( K \), and

\[ \| (E[b^K(X_i)b^K(X_i)'])^{-1} \| \leq 1/(\inf_{x \in [0,1]} f_X(x)) < \infty \]

uniformly in \( K \). This verifies the conditions of Lemma 7.2 for \( A = E[b^K(X_i)b^K(X_i)'] \). It follows by Lemma 7.2 that \( \| (E[b^K(X_i)b^K(X_i)'])^{-1} \|_{\ell^\infty} \lesssim 1 \), as required.

We now adapt the preceding arguments to the multivariate case. For any \( x = (x_1, \ldots, x_d) \in [0,1]^d \)
we define \( b^K(x) = \bigotimes_{l=1}^d b^{K_0}(x_l) \) where \( b^{K_0}(x_l) = (\varphi_{l,0}(x_l), \ldots, \varphi_{l,2^l-1}(x_l))' \) and \( K_0 = 2^l \).

Recall that \( K = 2^d \). For any \( x = (x_1, \ldots, x_d) \in [0,1]^d \) we have

\[ \| b^K(x) \|_{\ell^1} = \prod_{l=1}^d \| b^{K_0}(x_l) \|_{\ell^1} \]

\[ \leq \left((2N)^{2^l/2} \max\{\|\varphi_{l,0}\|_{\infty}, \|\varphi_{l,1}\|_{\infty}, \ldots, \|\varphi_{l,2^l-1}\|_{\infty}\}\right)^d \]

\[ \leq (2^{l/2})^d = \sqrt{K}. \] (131)

With slight abuse of notation we let \( X_{i_1}, \ldots, X_{i_d} \) denote the \( d \) elements of \( X_i \). For \( 0 \leq k_1, \ldots, k_d \leq 2^l - 1 \), Fubini’s theorem and a change of variables yields

\[ E \left[ \prod_{l=1}^d \varphi_{l,k_l}(X_{i_l}) \right] \leq \sup_{x \in [0,1]^d} f_X(x) \int_{\mathbb{R}^d} \left( \prod_{l=1}^d |\varphi_{l,k_l}(x_l)| \right) \, d\mu(x_1, \ldots, x_d) \]

\[ = \sup_{x \in [0,1]^d} f_X(x) \prod_{l=1}^d \left( \int_{\mathbb{R}} |\varphi_{l,k_l}(x_l)| \, d\mu(x_l) \right) \]

\[ \lesssim (2^{-l/2})^d = K^{-1/2}. \] (134)

This verifies the conditions of Lemma 7.1 and hence \( \| P_K \|_{\infty} \lesssim \| (E[b^K(X_i)b^K(X_i)'])^{-1} \|_{\ell^\infty} \).

The tensor product basis is an orthonormal basis with respect to Lebesgue measure on \( [0,1]^d \) (by Fubini’s theorem). Therefore, the minimum and maximum eigenvalues of \( E[b^K(X_i)b^K(X_i)'] \) may be shown to be bounded below and above by \( \inf_{x \in [0,1]^d} f_X(x) \) and \( \sup_{x \in [0,1]^d} f_X(x) \) as in the univariate case. Again, compact support of the \( \varphi_{l,k} \) and the tensor product construction implies that \( E[b^K(X_i)b^K(X_i)'] \) is banded: \( (E[b^K(X_i)b^K(X_i)'])_{k,j} = 0 \) whenever \( |k - j| > (2N - 1)^d \). This verifies the conditions of Lemma 7.2 for \( E[b^K(X_i)b^K(X_i)'] \). It follows by Lemma 7.2 that \( \| (E[b^K(X_i)b^K(X_i)'])^{-1} \|_{\ell^\infty} \lesssim 1 \), as
required. ■

**Theorem 7.1** Under conditions stated in Theorem 5.1, we have $\|P_{K,n}\|_\infty \lesssim 1\ wpa_1$ provided the following are satisfied:

(i) $\| (B'B/n) - E[b^K(X_i)b^K(X_i)'] \| = o_p(1)$, and

(ii) $\max_{1 \leq k \leq K} \frac{1}{n} \left\| \sum_{i=1}^n \left[ b_{Kk}(X_i) - E[b_{Kk}(X_i)] \right] \right\| = o_p(1)$.

**Proof of Theorem 7.1** Condition (ii) $\max_{1 \leq k \leq K} \frac{1}{n} \left\| \sum_{i=1}^n \left[ b_{Kk}(X_i) - E[b_{Kk}(X_i)] \right] \right\| = o_p(1)$ implies

$$\max_{1 \leq k \leq K} \frac{1}{n} \sum_{i=1}^n \left| b_{Kk}(X_i) \right| \lesssim \max_{1 \leq k \leq K} \left\| b_{Kk} \right\|_{L^1(X)} \lesssim K^{-1/2}$$

(135)

where the final inequality is by the proof of Theorem 5.1. Moreover, $\sup_x \| b^K(x) \|_{\ell_1} \lesssim \sqrt{K}$ by the proof of Theorem 5.1. It follows analogously to Lemma 7.1 that $\| P_{K,n} \|_\infty \lesssim \| (B'B/n)^{-1} \|_\infty wpa_1$ (noting that $B'B/n$ is invertible wpa_1 because $\| (B'B/n) - E[b^K(X_i)b^K(X_i)'] \| = o_p(1)$ and $\lambda_{K,n} \lesssim 1$).

Condition (i) $\| (B'B/n) - E[b^K(X_i)b^K(X_i)'] \| = o_p(1)$ implies (1) $\lambda_{\min}(B'B/n) \gtrsim \lambda_{\min}(E[b^K(X_i)b^K(X_i)'])$, (2) $\lambda_{\max}(B'B/n) \lesssim \lambda_{\max}(E[b^K(X_i)b^K(X_i)'])$, and (3) $\| (B'B/n)^{-1} \| \lesssim \| (E[b^K(X_i)b^K(X_i)'])^{-1} \|$ all hold wpa_1. Moreover, $\lambda_{\min}(E[b^K(X_i)b^K(X_i)']) \geq 1$ and $\lambda_{\max}(E[b^K(X_i)b^K(X_i)']) \lesssim 1$ by the proof of Theorem 5.1. It follows by Lemma 7.2 that $\| (B'B/n)^{-1} \|_{\ell_\infty} \lesssim 1$ wpa_1, as required. ■

**Proof of Theorem 5.2**. Condition (i) of Theorem 7.1 is satisfied because $\lambda_{K,n} \lesssim 1$ and the condition $\| (\tilde{B}'\tilde{B}/n) - I_K \| = o_p(1)$ under the conditions on $K$ (see Lemma 2.1 for the i.i.d. case and Lemma 2.2 for the weakly dependent case). Therefore,

$$\| (B'B/n) - E[b^K(X_i)b^K(X_i)'] \| \lesssim \left[ \lambda_{\min}(E[b^K(X_i)b^K(X_i)'])^{-1} \right] \| (\tilde{B}'\tilde{B}/n) - I_K \|$$

(136)

$$\lesssim \| (\tilde{B}'\tilde{B}/n) - I_K \| = o_p(1).$$

(137)

It remains to verify condition (ii) of Theorem 7.1. Let $b_{K1} = \varphi_{J,0}, \ldots, b_{KK} = \varphi_{J,2J-1}$ with $K = 2^{dJ}$ as in the proof of Theorem 5.1. Similar arguments to the proof of Theorem 5.1 yield the bounds $\| b_{Kk} \|_\infty \lesssim 2^{dJ/2} = \sqrt{K}$ uniformly for $1 \leq k \leq K$. Let $f_X(x)$ denote the density of $X$. Then by
\[ E[|b_{Kk}(X)|] \geq \left( \inf_{x \in [0,1]^d} f_X(x) \right) \int_{[0,1]^d} \left( \prod_{l=1}^d |\varphi_{J,k_l}(x_l)| \right) \, d\mu(x_1, \ldots, x_d) \tag{138} \]
\[ = \left( \inf_{x \in [0,1]^d} f_X(x) \right) \prod_{l=1}^d \left( \int_{[0,1]} |\varphi_{J,k_l}(x_l)| \, d\mu(x_l) \right). \tag{139} \]

A change of variables argument yields \( \int_{[0,1]} |\varphi_{J,k_l}(x_l)| \, d\mu(x_l) \geq 2^{-J/2} \) uniformly for \( 0 \leq k_l \leq 2^J - 1 \), and so \( E[|b_{Kk}(X)|] \gtrsim 2^{-dJ/2} = K^{-1/2} \) uniformly for \( 1 \leq k \leq K \).

For the \textbf{i.i.d. case}, define \( b_{Kk}^*(X_i) = n^{-1}(|b_{Kk}(X_i)| - E[|b_{Kk}(X_i)|])/(E[|b_{Kk}(X_i)|]) \) for each \( 1 \leq k \leq K \). It may be deduced from the preceding bounds and the fact that \( E[b_{Kk}(X_i)^2] = 1 \) that \( \|b_{Kk}^*\|_\infty \lesssim K/n \) and \( E[b_{Kk}^*(X_i)^2] \lesssim K/n^2 \). By the union bound and Bernstein’s inequality (see, e.g., pp. 192–193 of Pollard (1984)) we obtain, for any \( t > 0 \),

\[
P\left( \max_{1 \leq k \leq K} \left| \frac{1}{n} \sum_{i=1}^n |b_{Kk}(X_i)| - E[|b_{Kk}(X_i)|] \right| > t \right)
\leq \sum_{k=1}^K P\left( \left| \frac{1}{n} \sum_{i=1}^n |b_{Kk}(X_i)| - E[|b_{Kk}(X_i)|] \right| > \frac{t^2}{2c_1K/n + c_2K/nt} \right) \tag{140} \]
\[ \leq 2 \exp \left\{ \log K - \frac{t^2}{c_1K/n + c_2K/nt} \right\} \tag{141} \]

where \( c_1 \) and \( c_2 \) are finite positive constants independent of \( t \). The right-hand side of (141) vanishes as \( n \to \infty \) since \( K \log n/n = o(1) \).

For the \textbf{beta-mixing regressors case}, we may extend the proof for the i.i.d. case using a coupling argument similar to the proof of Theorem 1.2 to deduce that

\[
P\left( \max_{1 \leq k \leq K} \left| \frac{1}{n} \sum_{i=1}^n |b_{Kk}(X_i)| - E[|b_{Kk}(X_i)|] \right| > t \right)
\leq \frac{n}{q} \beta(q) + \exp \left\{ \log n - \frac{t^2}{c_1Kq/n + c_2Kq/nt} \right\}. \tag{142} \]

The right-hand side is \( o(1) \) provided \( \frac{n}{q} \beta(q) = o(1) \) and \( (qK \log n)/n = o(1) \). Both these conditions are satisfied under the conditions on \( K \), taking \( q = \gamma^{-1} \log n \) in the exponentially \( \beta \)-mixing case and \( q \asymp n^{\gamma/(1+\gamma)} \) in the algebraically \( \beta \)-mixing case. \hspace{1cm} \blacksquare
