Diabetic nephropathy (DN) is the leading cause of end-stage failure of the kidney, but the efficacy of currently available strategies for the prevention of DN remains unsatisfactory. In this study, we investigated the effects of free anthraquinones (FARs) extract, which was extracted from the rhubarb and purified by macroporous resin DM130 with gradient mixtures of ethanol/water as the lelution solvents, in high glucose-cultured glomerular mesangial cells (MCs). The cell proliferation was determined by CCK-8 assay, the levels of TGF-β1, CTGF, ColIV and FN proteins in the supernatant of MCs were measured by ELISA assays, and the mRNA levels of these four genes were detected by RT-PCR. The results showed that the increased proliferation of MCs, the mRNA levels and protein expression of TGF-β1, CTGF, ColIV and FN induced by high glucose were inhibited after the treatment with the FARs extract. This indicated that FARs extract could inhibit cell proliferation and the expression of main extracellular matrix induced by high glucose in MCs. The FARs extract exhibited potential values for prophylaxis and therapy of DN.

Key Words: Cell proliferation, Diabetic nephropathy, Extracellular matrix, Free anthraquinones of rhubarb, Mesangial cells

INTRODUCTION

Diabetic nephropathy (DN), also known as nodular diabetic glomerulosclerosis, is characterised by mesangial cell (MC) proliferation and excessive accumulation of extracellular matrix (ECM), which may ultimately lead to chronic renal failure [1]. The main ECM proteins such as type IV collagen (ColIV) and fibronectin (FN) are often used as the markers of fibrogenesis in many kidney fibrosis diseases including diabetic glomerulosclerosis [2-4]. In the complicated pathogenesis, hyperglycemia is the main initiation factor in the etiology of DN, which can activate multiple intracellular signalling factors (such as TGF-β1, reactive oxygen species), resulting in abnormalities in blood flow and the accumulation of ECM [5-7]. In these factors, TGF-β1 and its downstream mediator connective tissue growth factor (CTGF) are recognized as fibrogenic cytokines which play a critical role in the glomerulosclerosis of DN [7-9]. Currently, MCs are recognized as the major cells to secrete ECM [9]. Therefore, inhibiting the proliferation of MCs and the accumulation of ECM can be applied as a practical approach for treating or relieving DN.

However, there is no treatment available to arrest the progression for the end-stage renal failure. Therefore new therapeutic strategies in the management of diabetic nephropathy are really in demand. Chinese medical herbs are considered to be one of the most promising sources due to their variety of species and applications. Rhubarb (Dahuang in Chinese), one of best-known Traditional Chinese Medicine, has been widely used for thousands of years in China for its treatment of many diseases. Rhubarb contains five free anthraquinones (FARs), including rhein, emodin, aloe-emodin, chrysophanol, and physcion, which account for the main medicinal properties of rhubarb [10]. These FARs have been documented to have numerous therapeutic benefits, such as resisting high fat of blood [11], diminishing inflammation [12], accommodating immunity [13], exhibiting vasorelaxant effects [14] and antioxidant activities [15], suggesting its potential therapeutic value in the treatment...
of DN. Zheng et al. has found that rhein, one of anthraquinones, reversed the diabetic phenotype of mesangial cells over-expressing the glucose transporter (GLUT1) by inhibiting the hexosamine pathway [16]. Wang et al. reported that FARs extract had an effect on preventing Chronic Renal Failure [17]. However, seldom information about the FARs extract on the effects of glomerulosclerosis in DN could be found. Since cell proliferation and ECM accumulation play a vital role in the glomerulosclerosis of DN, it is essential to clarify the in vitro effects of the FARs extract on high glucose-cultured mesangial cell, which may be meaningful to the treatment of DN.

In this study, using gradient ethanol as the eluant, we purified the FARs extract by DM130 macroporous resin and tested its effects on the proliferation of MCs and the expression of main ECM (Col IV and FN) and ECM-related genes (TGF-β1 and CTGF) in high glucose-cultured mesangial cells. Our results will be beneficial to explore new drugs for the treatment of diabetic nephropathy.

**METHODS**

**Materials**

Rhubarb, purchased from Xuzhou traditional Chinese medicine factory (China) was identified as the dried roots of *Rheum palmatum* L. by Dr. Huankai Yao. Standard chemicals of five FARs (aloe-emodin, emodin, rhein, chrysophanol, and physcion) were obtained from Sichuan Weikeqi Biological Technology Co., Ltd (Sichuan, China) and resolved in methanol (MeOH) as the control solution. Rat MCs (No. HBZT-1) were obtained from Wuhan Boster Biological Technology Co. (Wuhan, China). DM130 macroporous resins were bought from Anhui Sanxing resin Biological Technology Co. Ltd (Anhui, China) and resolved in methanol (MeOH) as the control solution. Rat MCs (No. HBZT-1) were obtained from Wuhan Boster Biological Technology Co. (Wuhan, China). DM130 macroporous resins were bought from Anhui Sanxing resin Biological Technology Co. Ltd (Anhui, China) and resolved in methanol (MeOH) as the control solution. Rat MCs (No. HBZT-1) were provided by the China Center for Type Culture Collection (CCTCC) in Wuhan University. Cells were cultured in a Dulbeccos Modified Eagle’s Medium (DMEM, Gibco, Grand Island, NY, USA) that was supplemented with 100 μg/ml streptomycin, 100 U/ml penicillin, and 10% (v/v) fetal bovine serum. The cells were incubated at 37°C in a humidified atmosphere of 5% CO2. During the experiments, the cells were first exposed to a normal concentration of glucose (5.56 mmol/L) without serum for 12 h, and then treated with high glucose (HG, 25 mmol/L glucose), high glucose with 5 μg/ml FARs (FARsL), high glucose with 10 μg/ml FARs (FARsM), and high glucose with 20 μg/ml FARs (FARsH). The object drugs in the cell culture-FARs extract were dissolved in 20 μg/ml Dimethyl sulfoxide (DMSO) (as a solvent). Mannitol (MA) was used as a control to rule out the effect of osmotic pressure. The cells were harvested for analysis after 24 h of treatment.

**Cell proliferation assay**

Cell proliferation was examined by Cell Counting Kit-8 colorimetric method [18]. MCs were seeded into 96-well plates at a density of 1.0×10^4 per well. After 24 h, CCK-8 solution were added and cells continued to be cultured for another 2 h. Absorbance was read at 450 nm by visible spectrometry (Clinibio Co., Australia).

**Reverse transcription-polymerase chain reaction**

A reverse transcription polymerase chain reaction (RT-PCR) procedure was performed to determine the relative mRNA quantities of TGF-β1, CTGF, ColIV and FN in MCs. Total RNA was extracted from rat MCs with TRIzol Reagent according to the manufacturer’s instructions. The total RNA (0.5 μg) was converted into cDNA using the RevertAid™ First Strand cDNA Synthesis Kit with Random Hexamer primers. The upstream and downstream primers (Shanghai Sangon Company, China) of those genes were shown in Table 1. The reaction mixture was incubated at 48°C for 45 min to reverse transcript, then went into cycles. The cycle conditions of these genes were all set to: initial

| Gene names | Forward sequences | Reverse sequences |
|------------|------------------|------------------|
| TGF-β1     | 5'-AGTTGGCAGGATAATTGCAG-3' | 5'-TGGTGTGGTATACGAGGCTAG-3' |
| CTGF       | 5'-CTCAAGGAGCTGTGGAGATG-3' | 5'-CTCAGGAGGCTGTAATACG-3' |
| ColIV      | 5'-CTGCGTATTCCTTCGTGAT-3' | 5'-TCCAGGCTCTTCTCTATCTGGT-3' |
| FN         | 5'-GGCACTTGCAGCTGCGCT-3' | 5'-CCGTTAAGGGCTGTAATACG-3' |
| β-actin    | 5'-TCAAGGCTCATCATCTCGGCAAT-3' | 5'-AAAGAAGGTTGTAATAACGCA-3' |
Farls Compound Inhibits MC Proliferation and ECM Accumulation

CCK-8 assay was adopted to assess the impact of the Farls extract on MC proliferation. The proliferation of MCs was enhanced after 24 h exposure to high glucose (p < 0.01). The results showed that the cell proliferation rates in FARsL, FARsM and FARsH were significantly lower than those of HG group (p < 0.01). Meanwhile, the cell proliferation in the MA group was almost identical to those in the NG group and the DMSO group was not significantly different from the HG group, indicating that no obvious impacts were generated by the osmotic pressure and the vehicle. The above results indicated that administration of Farls compound significantly suppressed high glucose-induced MC proliferation (Fig. 2).

Effects of Farls compound on the mRNA levels of TGF-β1, CTGF, ColIV and FN

The RT-PCR results showed that the mRNA levels of TGF-β1, CTGF, ColIV and FN in the HG groups were elevated compared to those in the NG groups. The CTGF, ColIV and FN mRNA levels in the groups treated with 5, 10, 20 μg/ml Farls were all lower than those of the HG group. The TGF-β1 mRNA levels in groups treated with 10, 20 μg/ml Farls were also significantly decreased compared with those in the HG-treated groups. Significant changes in the levels of TGF-β1, CTGF, ColIV and FN mRNA between MA group and NG group were not found. The four genes in the DMSO group were also not remarkably different from those in the HG group. All these indicated that administration of Farls extract significantly decreased high glucose-induced the increase of TGF-β1, CTGF, ColIV and FN mRNA quantities (Fig. 3).

Effects of Farls compound on the proteins of TGF-β1, CTGF, ColIV and FN

The levels of these four proteins in the cell culture supernatant in the HG group were remarkably up-regulated compared to those in the NG group (p < 0.01). Importantly, treatment with 5, 10, 20 μg/ml Farls significantly decreased the levels of TGF-β1, CTGF, ColIV and FN induced by high glucose. There is no significant difference between the NG group and MA group on the secretion of these four proteins. DMSO also had no significant effect on the proteins levels. All these indicated that administration of Farls significantly reduced high glucose-induced the secretion of proteins were generated by the osmotic pressure and the vehicle. The above results indicated that administration of Farls compound significantly suppressed high glucose-induced MC proliferation (Fig. 2).

**RESULTS**

The ingredient identification of Farls

According to results of HPLC, the chromatographic peaks of the analytes were confirmed by comparing their retention time with those of the reference compounds. The main ingredients were identified as aloe-emodin, rhein, and emodin (Fig. 1).

Effects of Farls extract on the MC proliferation

CCK-8 assay was adopted to assess the impact of the FARs extract on MC proliferation. The proliferation of MCs was enhanced after 24 h exposure to high glucose (p < 0.01). The results showed that the cell proliferation rates in FARsL, FARsM and FARsH were significantly lower than those of HG group (p < 0.01). Meanwhile, the cell proliferation in the MA group was almost identical to those in the NG group and the DMSO group was not significantly different from the HG group, indicating that no obvious impacts were generated by the osmotic pressure and the vehicle. The above results indicated that administration of Farls compound significantly suppressed high glucose-induced MC proliferation (Fig. 2).

Enzyme-linked immunosorbent assay

The levels of TGF-β1, CTGF, ColIV and FN in the supernatant of MCs were determined by enzyme-linked immunosorbent assay (ELISA). The medium of MCs was collected and centrifuged at 13,000 g for 15 mins to pellet the debris. The levels of these four proteins were determined according to the manufacturer’s instructions. The colorimetric reaction was measured at 450 nm.

Statistical analysis

Data were expressed as means±SD. Statistical analyses were performed using the paired t-test for two data comparison and one-way analysis of variance (ANOVA) with Dunnett’s test for multiple data comparison. A value of p < 0.05 was considered significant.

**Fig. 2.** The cell proliferation rates in FARs-treated MCs. The cells were exposed to DMEM culture media containing different substances, namely: 5.56 mmol/L glucose in the NG group, 5.56 mmol/L glucose + 19.44 mmol/L mannitol in the MA group, 25 mmol/L glucose in the HG group, 25 mmol/L glucose + 20 μg/ml DMSO in the DMSO group, 25 mmol/L glucose + 5 μg/ml FARs in the FARsL group, 25 mmol/L glucose + 10 μg/ml FARs in the FARsM group, 25 mmol/L glucose + 20 μg/ml FARs in the FARsH group, respectively. Mean±SD, n=4. **p<0.01, compared with the NG group; *p<0.01, compared with the HG group.
The mRNA levels of TGF-β1, CTGF, ColIV and FN in the FARs-treated MCs. (A) Agarose electrophoresis of RT-PCR products amplified from the total RNA extracts of mesangial cells, β-actin was used as the internal standard in each sample. (B∼E) RT-PCR data for the mRNA relative quantity of TGF-β1, CTGF, ColIV and FN performed by densitometric analysis. Mean±SD, n=4. **p<0.01, compared with the NG group; ##p<0.01, #p<0.05, compared with the HG group.

The relative quantity of TGF-β1, CTGF, ColIV and FN proteins in the supernatant of FARs-treated MCs. (A) The relative quantity of TGF-β1 and CTGF proteins. (B) The relative quantity of Col IV and FN proteins. Mean±SD, n=4. **p<0.01, compared with the NG group; ##p<0.01, #p<0.05, compared with the HG group.

DISCUSSION

MC is one type of specialized vascular smooth muscle cells around the capillaries of the renal glomerulus, serving functions of structural support and regulating glomerular filtration rate. MC proliferation and the progressive accumulation of ECM in the mesangial areas are the major characteristics of diabetic glomerulosclerosis [1]. Therefore, reversing changes in the MCs proliferation and extracellular matrix might play a key role in delaying the progression of diabetic nephropathy. In the complicated mechanisms of DN, the pathway of hyperglycaemia-TGF-β1-ECM is important. TGF-β1, highly expressed in the kidneys of diabetes [7,8], contributes to the accumulation of ECM through the Smad pathway [4,8]. The administration of neutralizing antibodies against TGF-β1 to diabetic mice or mesangial cells has been shown to prevent the accumulation of ECM in the kidneys of diabetic mice or mesangial cells [19]. TGF-β1, acting as downstream of TGF-β1, has been shown to mediate expression of ECM proteins in response to various external perturbations [18,20]. Moreover, CTGF facilitates TGF-β1 signaling and consequently promotes renal fibrosis [19]. It is becoming clear that the coordinated expression of TGF-β1 and CTGF is crucial for the induction of ECM proteins and thus, for the development of DN [7].

In the present study, we extracted free anthraquinones compounds, including rhein, emodin, aloe-emodin, from rhubarb and found that administration of FARs extract significantly suppressed the cell proliferation, the mRNA and protein levels of TGF-β1, CTGF, ColIV and FN induced by high glucose. The effects and mechanisms of FARs extract on DN remain to be fully understood. Rhein, one of FARs, was found to have an ability of resisting the renal fibrosis in DN rats [11]. Guo et al. found that rhein inhibits extracellular matrix accumulation induced by TGF-β1, which might partly account for the role of rhein in preventing and retarding the progression of diabetic nephropathy [21]. Emodin (another FARs) was found to ameliorate renal dysfunction in diabetic nephropathy rats by its inhibition of the activation of p38 MAPK pathway and downregulation of the expression of fibronectin [6]. And Li et al. found that emodin had the ability of suppressing cell proliferation and fibronectin expression in rat mesangial cells cultured under high glucose [22]. Meanwhile, aloe-emodin (the third FARs) was also reported to have antiproliferative activity in various cancer cell lines [23,24], which might partly explain the inhibition of FARs on MC proliferation. The function of FARs compound on HG-cultured MCs may be attributed to the combination of the anthraquinone mixtures. However, seldom researches about the compound of FARs were found in DN, probably due to the pollution produced in the FARs’ extraction and separation process. The traditional extraction of FARs tends to use the petroleum ether, benzene, chloroform, or ethyl ether as the solvents [25-27], producing toxicity in some degree. In the present study, we adopted the ethanol as the solvent, improving the safety of extracts and reducing the pollution of environment, which was bet-
FARs Compound Inhibits MC Proliferation and ECM Accumulation

This study confirmed the effectiveness of our FARs extract on inhibiting ECM accumulation and cell proliferation in high glucose-cultured MCs, which may facilitate the finding of new drugs to prevent the progression of DN. Further researches are under way to comparing the effects of FARs extract with the single free anthraquinone extracted from the rhubarb and observing their effects on DN animals.
