ABSTRACT: We study Yukawa Renormalization Group (RG) running effects in the context of the Standard Model Effective Theory (SMEFT). The Yukawa running being flavour dependent leads to RG-induced off-diagonal entries, so that initially diagonal Yukawa matrices at the high scale have to be rediagonalized at the electroweak (EW) scale. Performing such flavour rotations can lead to flavour violating operators which differ from the ones obtained through SMEFT RG evolution. We show, that these flavour rotations can have a large impact on low-energy phenomenology. In order to demonstrate this effect, we compare the two sources of flavour violation numerically as well as analytically and study their influence on several examples of down-type flavour transitions. For this purpose we consider $B_s - \bar{B}_s$ mixing, $b \to s\gamma$, $b \to s\ell\ell$ as well as electroweak precision observables. We show that the rotation effect can be comparable or even larger than the contribution from pure RGE evolution of the Wilson coefficients.

\textbf{ArXiv ePrint:} 2005.12283
1 Introduction

The Standard Model (SM) of particle physics describes a plethora of phenomena with an extraordinary precision. Nevertheless, several experimental results as well as theoretical considerations point to an extension of the SM. A convenient way to parameterize such New Physics (NP) effects is to adopt an Effective Field Theory (EFT) approach. In such a setup, NP effects are described in terms of Wilson coefficients of higher-dimensional operators. One of the most popular EFTs is the SM Effective Field Theory (SMEFT) [1–4], which has been studied extensively in the literature. The complete one-loop running of the SMEFT Wilson coefficients [5–7] as well as the matching from SMEFT onto the Weak Effective Theory (WET) below the electroweak (EW) scale is known [8–11]. Furthermore, there are several computational tools dealing with various aspects of the SMEFT [12–21]. Many NP analyses have been carried out in the context of SMEFT in recent years, which take into account the RGE evolution of the Wilson coefficients. In this article, we will lay special focus on flavour observables in the down-sector within the SMEFT (see for example [22–33]).
Yukawa interactions provide a source of flavour violation in the SM, as they mix quarks and leptons of different generations. Being scale dependent, their running has to be taken into account when considering the RGE evolution of Wilson coefficients. Such Yukawa RGE effects can have a large impact on flavour observables. This is especially the case for the top-Yukawa coupling, which is $\mathcal{O}(1)$ above the EW scale and therefore comparable to QCD running. However, the flavour-dependent Yukawa evolution induces off-diagonal terms in the Yukawa matrices, which therefore have to be (re-)diagonalized at the scale of interest to recover the mass eigenbasis. The rotation matrices involved in this diagonalization procedure also enter higher dimensional operators and therefore influence the size of their Wilson coefficients. This back-rotation effect is often neglected in the literature, when performing studies of flavour violating processes. In this article we show, that the diagonalization effect of the Yukawa matrices has comparable or even larger effects on the bounds of SMEFT Wilson coefficients than the mere Yukawa running. Taking into account only the Yukawa RGEs and neglecting the diagonalization can lead to an over- or underestimation of the size of Wilson coefficients. We illustrate this point by considering various examples of FCNC processes in the down-sector. They include the $F = 2$ observables $S$, and $M_s$, the $b \to s \gamma$ transition observables $\text{BR}(B \to X_s \gamma)$, $\text{BR}(B \to K^* \gamma)$, $S_{K^* \gamma}$ as well as $R_K$, $B_s \to \mu^+ \mu^-$ and $B_s \to \ell^+ \ell^-$ for $b \to s \ell^+ \ell^-$. For the theoretical predictions of these observables we use the Python package flavio [34]. The RG evolution and matching is performed using wilson [15]. All the results have been confirmed using leading-log (LL) analytic solutions for the RGEs, as well as explicit expressions for the rotation matrices.

The rest of the article is organized as follows: In section 2 we review flavour rotations in the SM. Section 3 is dedicated to the SMEFT Wilson coefficients at the EW scale and describes the procedure used for the numerical analysis. In section 4 we compare RG running and rotation effects using different examples of flavour violating observables like $B_s - \bar{B}_s$ mixing, $b \to s \gamma$ as well as $b \to s \ell \ell$. Finally, we present our conclusions in section 5. Explicit values of the diagonalization and LL contributions to the considered Wilson coefficients are given in the appendix.

## 2 Field rotations and Yukawa running

The SM fermions acquire their masses through Higgs interactions after EW symmetry breaking. The Yukawa Lagrangian describing such Higgs-fermion interactions is given by:

$$-\mathcal{L}_Y = Y_u (\bar{q} \varphi u) + Y_d (\bar{q} \varphi d) + Y_e (\bar{\ell} \varphi e) + \text{h.c.},$$  \hspace{1cm} (2.1)

where $Y_{u,d,e}$ are the Yukawa matrices and $\varphi$ and $\varphi'$ denote the Higgs field and its conjugate, respectively. The Yukawa matrices are in general complex $3 \times 3$ matrices. A basis change from the weak eigenbasis to the physical mass basis is performed by diagonalizing the Yukawa matrices. This basis change is performed through unitary $3 \times 3$ matrices in flavour space in the following way:

$$u' = U_{uL} u_L, \quad d' = U_{dL} d_L, \quad u' = U_{uR} u, \quad d' = U_{dR} d, \quad \ell' = U_{\ell} \ell, \quad e' = U_e e,$$  \hspace{1cm} (2.2)
where the primed and unprimed fields denote the weak and mass eigenstates respectively. By applying the fermion field rotations of eq. (2.2) the Yukawa matrices become diagonal with real positive entries, representing the nine fermion masses.\footnote{A singular value decomposition is performed for each Yukawa matrix, which takes the following form: \( Y_f = U_{fL} Y^{\text{Phys}} U_{fR}^\dagger \) with the left- and right-handed rotation matrices \( U_{fL,R} \) for the fermion indices \( f = u, d, e \). The rotation matrices are unique for a given quark phase convention.} For the up- and down-type Yukawas, after choosing the quark phases appropriately another four physical parameters remain, which define the CKM matrix. Below the EW scale, one has the freedom to transform the left- and right-handed quark fields separately by using different unitary transformations. However, since we are interested in Yukawa running effects in the SMEFT, the Yukawa matrices have to be specified above the EW scale. In the unbroken phase only five unitary transformations can be performed, one for each of the five fermion representations of the full SM gauge group. We denote them in the following way:

\[
q' = U^{\text{SMEFT}} q, \quad u' = U^{\text{SMEFT}}_{uR} u, \quad d' = U^{\text{SMEFT}}_{dR} d, \quad \ell' = U^{\text{SMEFT}}_{\ell} \ell, \quad e' = U^{\text{SMEFT}}_{e} e. \tag{2.3}
\]

Having only five rotation matrices at hand allows to diagonalize just two of the three Yukawa matrices above the EW scale. Since we are interested in flavour observables in the down-sector, we adopt the Warsaw-down basis defined in [13].\footnote{See also [35] for a generalization to the full Warsaw basis.} In this basis, the down-type and lepton Yukawa matrices are diagonal, whereas the up-type Yukawa matrix is rotated by the CKM matrix \( V \). At the NP scale \( \Lambda \) one has

\[
Y_d(\Lambda) = \text{diag}(y_d, y_s, y_b), \quad Y_u(\Lambda) = V^\dagger \text{diag}(y_u, y_c, y_t), \quad Y_e(\Lambda) = \text{diag}(y_e, y_{\mu}, y_{\tau}). \tag{2.4}
\]

This simple form of the Yukawa matrices however only holds at a single scale, \( \Lambda \) in this case, and is broken once RG evolution is considered. Namely, running effects generate off-diagonal entries in the Yukawa matrices and therefore the theory parameters are not given in the Warsaw-down basis anymore. The generation of the off-diagonal entries can be understood from the first lines of the Yukawa \( \beta \)-functions in eqs. (A.1)–(A.2) in appendix A. Considering \( Y_d \), the leading term of its \( \beta \)-function is proportional to the up-quark Yukawa matrix \( Y_u \), which is non-diagonal in the down-basis. Indeed, at the EW scale \( \mu_{\text{EW}} \) in the first LL approximation and keeping only the dominant \( y_t \)-contribution one finds:

\[
Y_d(\mu_{\text{EW}}) = Y_d(\Lambda) - \delta Y_d \frac{3 y_t^2}{32 \pi^2} \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right) + \ldots , \tag{2.5}
\]

where

\[
\delta Y_d = \begin{pmatrix}
    y_d \lambda_{t}^{dd} & y_d \lambda_d^{ds} & y_b \lambda_b^{db} \\
    y_d \lambda_{t}^{ds} & y_d \lambda_t^{ss} & y_b \lambda_b^{sb} \\
    y_d \lambda_{t}^{db} & y_d \lambda_t^{bs} & y_b \lambda_b^{bb}
\end{pmatrix}, \quad \lambda_i^{ij} = V_{ti}^* V_{tj} . \tag{2.6}
\]

Note that for simplicity we have not shown the SMEFT contribution to the RG running of \( Y_d \), however we include all terms in (A.1)–(A.3) in our numerical analysis. As shown in eq. (2.5), the down-type Yukawa matrix is off-diagonal at the EW scale. However, in order...
to examine physical processes, a basis change to the mass basis has to be performed, as in eq. (2.2). This concludes the evolution of the down-type Yukawa matrix from the NP scale down to $\mu_{\text{EW}}$. In short, $Y_d$ started by construction from a diagonal form at the high scale $\Lambda$, became off-diagonal at the EW scale through RGE effects and is finally diagonalized at the EW scale. We refer to the latter diagonalization as back-rotation to the down-basis. Finally we note, that the back-rotation effect is not inherent to the SMEFT but occurs also in other BSM scenarios. For instance it was analyzed in the context of 2HDMs in [36, 37].

3 SMEFT Wilson coefficients at the EW scale

We are now in a position to discuss the running of the SMEFT Wilson coefficients together with the Yukawa matrices. The evolution of the Wilson coefficients down to the EW scale proceeds in two steps which are shown in figure 1 and described in the following:

**Step 1.** The Wilson coefficients are evolved from the high scale $\Lambda$ down to the EW scale $\mu_{\text{EW}}$ using the full SMEFT RG equations. In the LL approximation one finds

$$\tilde{C}_a(\mu_{\text{EW}})_{ij} = [C_a(\Lambda)]_{ij} + \frac{\beta_{ab}^{ijkl}}{16\pi^2} \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right) [C_b(\Lambda)]_{kl},$$

(3.1)

where $a,b$ label different Wilson coefficients, $i,j,k,l$ are flavour indices and $\beta$ denotes the $\beta$-function of the corresponding Wilson coefficient. The tilde (~) on the left-hand side of eq. (3.1) denotes the fact that Wilson coefficients at the EW scale are not in the down-basis anymore, but in a shifted-down basis which we will call the tilde-basis. As explained in the previous section, this is due to the off-diagonal Yukawa elements generated through the running from $\Lambda$ to $\mu_{\text{EW}}$. Furthermore, it is important to note that due to the RG evolution governed by Yukawa couplings, the flavour indices at the EW scale can be different from the ones at the NP scale. As we are interested in flavour observables in the down-sector, the next step consists of changing from the tilde-basis $\tilde{C}_i$ back to the down-basis $C_i$:

**Step 2.** At the EW scale, the Wilson coefficients $\tilde{C}_a(\mu_{\text{EW}})$ are rotated back to the down-basis:

$$[C_a(\mu_{\text{EW}})]_{ij} = U_{ik}^\dagger [\tilde{C}_a(\mu_{\text{EW}})]_{kl} U_{lj},$$

(3.2)

where $i,j,k,l$ are flavour indices and $U_{ij}$ denote the rotation matrices in eq. (2.2). This back-rotation to the down-basis is key for the study of down-type flavour observables, since it transforms the involved fields into mass eigenstates. It is important to note that below the EW scale no further back-rotation is necessary, since off-diagonal Yukawa elements can not be generated through QCD or QED interactions.$^4$ As we will show in the next section, the impact of the back-rotation given in eq. (3.2) on the size of the Wilson coefficient can be comparable or even larger than the one coming from the LL running in eq. (3.1). It is therefore compulsory to take this effect into account when studying flavour processes within the SMEFT framework.

---

$^3$A similar expression exists for four-fermi operators with four flavour indices.

$^4$We note that this statement holds only when operators up to dimension six are considered and small double insertions of dipole operators are neglected.
\[
\begin{align*}
\kappa^{ij}_{\text{RGE}} &= \frac{\lambda^{ij}}{16\pi^2} \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right),
\end{align*}
\]

In the second case however, the suppression is due to small elements of the rotation matrices involved. Let us illustrate the latter with a concrete example by computing explicitly the down-type rotation matrices in eq. (2.2).

Evolving the down-basis Yukawa matrices from $\Lambda = 3$ TeV down to the EW scale one finds for the down-type rotation matrices

\[
\begin{align*}
U_{dR} &= \begin{pmatrix}
-0.93 + 0.37i & 1.6 \cdot 10^{-6} + 2.5 \cdot 10^{-8} i & -7.2 \cdot 10^{-7} \\
-1.1 \cdot 10^{-6} + 1.1 \cdot 10^{-6} i & -0.93 + 0.37i & 6.2 \cdot 10^{-5} - 2.6 \cdot 10^{-5} i \\
5.2 \cdot 10^{-7} - 5 \cdot 10^{-7} i & -6.3 \cdot 10^{-5} + 2.4 \cdot 10^{-5} i & -0.93 + 0.37i
\end{pmatrix}, \\
U_{dL} &= \begin{pmatrix}
-0.93 + 0.37i & 1.6 \cdot 10^{-5} + 2.5 \cdot 10^{-7} i & -3.8 \cdot 10^{-4} \\
-1.2 \cdot 10^{-5} + 1.1 \cdot 10^{-5} i & -0.93 + 0.37i & 1.6 \cdot 10^{-3} - 6.7 \cdot 10^{-4} i \\
2.7 \cdot 10^{-4} - 2.6 \cdot 10^{-4} i & -1.6 \cdot 10^{-3} + 6.1 \cdot 10^{-4} i & -0.93 + 0.37i
\end{pmatrix}.
\end{align*}
\]

Figure 1. The RG running of the down-basis SMEFT Wilson coefficients from the new physics scale $\Lambda$ to the EW scale $\mu_{\text{EW}}$ is shown. Down-type Yukawa running generates a tilde-basis ($\tilde{C}_a$), which has to be rotated back to the down-basis ($C_a$) at the EW scale. Subsequently, the Wilson coefficients are matched onto the WET and further evolved down to lower scales ($\mu_{\text{Low}}$) to estimate flavour observables.

From the two steps discussed above one finds, that there are two ways of how flavour changing contributions can arise from operators that conserve flavour. These two possibilities are

- through Yukawa running effects above the EW scale, as described in step 1,
- through back-rotation at the EW scale, as described in step 2.

Both ways of generating flavour changing operators come with a suppression factor. In the first case, the EW scale Wilson coefficients are suppressed by a typical factor of

\[
\kappa^{ij}_{\text{RGE}} = \frac{\lambda^{ij}}{16\pi^2} \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right).
\]
The rotation matrix $U_{u_L}$ is fixed through the relation $V = U_{u_L}^T U_{d_L}$ and $U_{e_L}$ as well as $U_{e_R}$ are identity matrices, assuming there are no right-handed neutrinos. The following comments on the rotation matrices in eqs. (3.4)–(3.5) are in order:

- Several off-diagonal elements in $U_{d_L}$ are of the same order as $\kappa_{RGE}^{p} \approx 9 \times 10^{-4} - 2 \times 10^{-5} i$, the typical suppression factor resulting from the dominant top-Yukawa running.

- Even though in general the largest elements of $U_{d_R}$ are roughly one order of magnitude smaller than the corresponding $\kappa_{RGE}$ factors, they can still have a large influence. The impact of $U_{d_R}$ depends on the Wilson coefficient in question and on the considered low energy process. For instance, there are examples where the top-Yukawa running effect vanishes and therefore back-rotation generates the only suppression.

- The elements of the rotation matrices are in general complex. This implies that complex Wilson coefficients can be generated at the EW scale, albeit starting with real coefficients at the high scale $\Lambda$. Such CP violating effects have for instance been described in the context of Kaon decays in [38].

4 Yukawa running and flavour observables

Several operators in the Warsaw basis contribute to flavour observables in the down-sector, which we collect in table 1. In the following we examine their impact due to back-rotation by studying several examples of flavour violating processes. In this regard, we choose
a strongest set of constraints for a given SMEFT operator. Furthermore, the effects of back-rotation and RG running are compared to each other. We assume the considered Wilson coefficients to be in the down-basis at the high scale of $\Lambda = 3 \text{ TeV}$. From there the complete one-loop RGE SMEFT running down to the EW scale is taken into account. Next the back-rotation is performed to have the Wilson coefficients in the down-basis. After the tree-level matching onto WET the Wilson coefficients are scaled further down to the characteristic scale $\mu_{\text{Low}}$ of the considered process. Also in WET, the complete one-loop running is taken into account [39, 40]. The running and matching is performed using the python package w\text{ilson} [15]. The full procedure is visualized in figure 1. For convenience we report for all considered Wilson coefficients numerical values for the back-rotation and LL effects in appendix. B. In the following examples we will consider only single flavour changes corresponding to a single insertion of the rotation matrices in eqs. (3.4)–(3.5), as further insertions will be suppressed.

4.1 (\textit{LL})(\textit{RR}) operators

We start our analysis by examining $\Delta B = \Delta S = 2$ processes.\footnote{In a fully general analysis the one-loop matching contributions should be taken into account, since such finite terms could be of the same size as the corresponding logarithmic terms from RG mixing. In this analysis we will however refrain from including such terms, since we are interested in comparing Yukawa against other SMEFT one-loop running effects.} We consider the following effective Lagrangian describing such flavour transitions in the WET:

$$L_{\Delta B = \Delta S = 2} = \sum_i C_i(\mu) O_i + \text{h.c.},$$

(4.1)

with the effective operators:

$$O_{\text{VLL}} = [s^\gamma_{\mu} P_L b][s^\gamma_{\mu} P_L b],$$

$$O_{\text{LR},1} = [s^\gamma_{\mu} P_L b][s^\gamma_{\mu} P_R b], \quad O_{\text{LR},2} = [s P_L b][s P_R b],$$

(4.2)

together with the chirality-flipped operator VRR obtained from interchanging $P_L \rightarrow P_R$ in VLL. We begin our discussion by examining the Wilson coefficients $C_{\text{q}_d}^{(1)}$ and $C_{\text{q}_d}^{(8)}$. Their tree-level matching contributions to the corresponding WET operators in eq. (4.2) are given by [8]

$$C_{\text{LR},1} = \frac{1}{\Lambda^2} \left( C_{\text{q}_d}^{(1)} \right)_{2323} - \frac{C_{\text{q}_d}^{(8)} \left( 2323 \right)}{2N_c}, \quad C_{\text{LR},2} = -\frac{1}{\Lambda^2} C_{\text{q}_d}^{(8)} \left( 2323 \right).$$

(4.3)

Following the two-step procedure of obtaining a certain flavour combination at the EW scale (see eqs. (3.1)–(3.2)), we find the following contributions to the Wilson coefficients of eq. (4.3):

$$\left[ C_{\text{q}_d}^{(1,8)} \right]_{2323}(\mu_{\text{EW}}) \approx \left( U_{d_L}^\dagger \right)_{23} \left[ C_{\text{q}_d}^{(1,8)} \right]_{3323}(\mu_{\text{EW}}) + \left( U_{d_R}^\dagger \right)_{23} \left[ C_{\text{q}_d}^{(1,8)} \right]_{2333}(\mu_{\text{EW}})$$

$$+ \frac{y_d^2 V_{tb} V_{tb}^*}{32\pi^2} \left[ C_{\text{q}_d}^{(1,8)} \right]_{3323}(\Lambda) \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right),$$

(4.4)

\footnote{For a more general discussion of $\Delta F = 2$ processes in SMEFT we refer to [41].}
Figure 2. Diagrams describing the RGE mixing of four-fermi operators due to up-type Yukawa interactions in SMEFT. The left diagram shows the up-type Yukawa contribution to the self-energy of the quark field $q$, which contributes to its wave function renormalization. The right diagram shows a typical example of operator mixing induced by Yukawa wave function renormalization.

where the first line is due to back-rotation and the second one results from LL running. Feynman diagrams describing the SMEFT running are depicted in figure 2. In eq. (4.4) we have omitted higher powers of the rotation matrices as well as LL terms which are not enhanced by $y_t^2$, since such contributions are further suppressed. Furthermore, on the r.h.s. we omit the flavour combinations 2223 and 2322, since they lead to very similar results as the ones we are about to discuss in the following. Also, large Yukawa mixing effects due to $\bar{\psi}^2 H D$ operators have been studied in [30], and we will refrain from discussing them here. Finally, we suppress diagonal elements of the rotation matrices, which can in principle change the sign of the Wilson coefficients. We study the effect of the Wilson coefficients $[C_{qd}^{(1,8)}]_{3233}$ and $[C_{qd}^{(1,8)}]_{3323}$ on the mass difference $\Delta M_s$ of the $B_s$ mesons, as well as the CP asymmetry $S_{\psi\phi}$. The SM predictions of these observables are given by:

$$\Delta M_s^{\text{SM}} = (18.7 \pm 1.3) \text{ ps}^{-1}, \quad S_{\psi\phi}^{\text{SM}} = (3.87 \pm 0.23) \times 10^{-2}, \quad (4.5)$$

and their experimental values by [42]

$$\Delta M_s^{\text{exp}} = (17.76 \pm 0.02) \text{ ps}^{-1}, \quad S_{\psi\phi}^{\text{exp}} = (3.3 \pm 3.3) \times 10^{-2}. \quad (4.6)$$

The result of imposing these constraints on the Wilson coefficients of eq. (4.4) is given in figure 3, in which the allowed regions for the real and imaginary parts of $[C_{qd}^{(1)}]_{3323}$ and $[C_{qd}^{(1)}]_{2333}$ are shown.

The orange region in figure 3 left shows the 1- and 2$\sigma$ contours for $[C_{qd}^{(1)}]_{3323}$ in the case where only the running from the high scale $\Lambda$ to the EW scale is considered. The green region includes also the back-rotation effect, given in the first line of eq. (4.4). The allowed region is largely reduced once back-rotation is taken into account, since its contribution is one order of magnitude larger than the one from RGE evolution (see table 2). For $[C_{qd}^{(1)}]_{2333}$ the effect is even more pronounced. Since there is no RGE contribution from this operator to the $\Delta F = 2$ observables, it is basically unconstrained in this approximation. However, performing back-rotation at the EW scale reduces the allowed region drastically, as shown by the green region in figure 3 right.
A similar situation is encountered for the real parts of $C_{qd}^{(1)}$ and $C_{qd}^{(8)}$, shown in figure 4. The linear relation between the two Wilson coefficients results from the matching conditions of eq. (4.3) and the LR contribution to $\Delta M_s$ (see e.g. eq. (29) in [43]). As before, the RGE-only part (orange) of the matching results in a much wider allowed region compared to the case where the full matching (green) including back-rotation is considered.

### 4.2 ($LL$)(\overline{LL}) operators

In this subsection we consider the contributions from the Wilson coefficients $C_{qq}^{(1)}$ and $C_{qq}^{(3)}$ to the previously discussed $\Delta F = 2$ observables. Their tree-level matching contribution to the WET Lagrangian in eq. (4.1) reads [8]

$$C_{VLL} = \frac{1}{\Lambda^2} \left( C_{qq}^{(1)}_{2323} + C_{qq}^{(3)}_{2323} \right).$$

(4.7)

The Wilson coefficients $[C_{qq}^{(1)}]_{2323}$ and $[C_{qq}^{(3)}]_{2323}$ receive contributions from both back-rotation and LL running at the EW scale:

$$[C_{qq}^{(1,3)}]_{2323}(\mu_{\text{EW}}) \approx (U_{d_L}^\dagger)_{23} [C_{qq}^{(1,3)}]_{2333}(\mu_{\text{EW}}) + \frac{y_t^2 V_{ts} V_{tb}}{16\pi^2} [C_{qq}^{(1,3)}]_{2333}(\Lambda) \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right),$$

(4.8)

where we have neglected small contributions or contributions with similar numerical outcome. The full set of contributions is given in table 3. Figure 5 shows the contour plots for $[C_{qq}^{(1)}]_{2333}$ and $[C_{qq}^{(3)}]_{2333}$, subject to the $\Delta M_s$ and the CP asymmetry $S_{\psi^0}$. The orange and green areas are the allowed regions when RGE evolution or RGE + back-rotation are taken into account, respectively. The Wilson coefficients are assumed to be generated at the NP scale $\Lambda = 3$ TeV.

Note that the Wilson coefficients $[C_{qq}^{(1,3)}]_{2333}$ also contribute to $D^0 - \overline{D}^0$ mixing, but as the SM contributions are poorly known due to the long-distance effects we preferred to use $B_s$-mixing as a constraint.
region, including only RGE evolution, is much larger than the green one, where also back-
rotation is taken into account. As can be seen from table 3 back-rotation provides a real 
contribution to \([C_{qq}^{(1,3),3323}]\) at the EW scale which is roughly one order of magnitude larger 
than the one from LL running. This leads to a much larger contribution to the \(\Delta F = 2\) 
observables and therefore strongly constrains the Wilson coefficients around zero.

As a further example of \((LL)(LL)\) operators we study the back-rotation effect of the 
semi-leptonic operator \(C_{\ell q}^{(1)}\). For this purpose we consider the effective Lagrangian 
\[
L^{b\to s\mu\mu} = N\left(C_{9}^{\mu\mu}O_{9}^{\mu\mu} + C_{10}^{\mu\mu}O_{10}^{\mu\mu}\right),
\]
with the normalization constant 
\[
N = \frac{4G_F}{\sqrt{2}}V_{tb}V_{ts}^*,
\]
and the semi-leptonic WET operators 
\[
O_{9}^{\mu\mu} = \frac{e^2}{16\pi^2}(\bar{s}\gamma_\nu P_L b)(\bar{\mu}\gamma_\nu\mu), \quad O_{10}^{\mu\mu} = \frac{e^2}{16\pi^2}(\bar{s}\gamma_\nu P_L b)(\bar{\mu}\gamma_\nu\gamma_5\mu),
\]
relevant for \(b \to s\mu^+\mu^-\) transitions. The tree-level contributions to these operators coming 
from \([C_{\ell q}^{(1)}]\) and \([C_{\ell q}^{(3)}]\) are given by \([8]\) 
\[
C_{9}^{\mu\mu} = -C_{10}^{\mu\mu} = \frac{1}{\Lambda^2 N e^2} [C_{\ell q}^{(1)}]_{2223}.
\]

In our analysis of \([C_{\ell q}^{(1)}]_{2223}\) we will focus on self-mixing as well as on the flavour-
diagonal case \([C_{\ell q}^{(1)}]_{2222}\), whereas the remaining contributions can be found in table 4. In
this case, the Wilson coefficient $C_{2222}^{(1)}$ at the EW scale is given by:

$$
[C_{2222}^{(1)}]_{\text{EW}} (\mu) \approx (U_{dL})_{23} \left[ C_{2222}^{(1)} \right]_{\text{EW}} + \frac{y_t^2 V_{ts}^* V_{tb}}{32\pi^2} \left[ C_{2222}^{(1)} \right]_{\text{EW}} (\Lambda) \ln \left( \frac{\Lambda}{\text{EW}} \right), \tag{4.13}
$$

where the first and second term is due to back-rotation and LL running, respectively. In eq. (4.13) we have omitted the self-mixing part but take it into account in our analysis below.

In the following we impose the binned $\mu - e$ ratio $R_{K^*} = (R_{\mu e})$ of $B^0 \to K^{*0} \ell^+ \ell^-$, the binned $q^2$ distribution of the branching ratio for $B_s \to \phi \mu^+ \mu^-$ as well as $\text{BR}(B_s \to \mu^+ \mu^-)$.

Their SM predictions are given by:

$$
[R_{K^*}^\text{SM}]_{[1,1,6,0]} = 1.00, \\
\text{BR}^\text{SM} (B_s \to \mu^+ \mu^-) = (3.61 \pm 0.19) \times 10^{-9}, \tag{4.14}
$$

$$
\left( \frac{d\text{BR}^\text{SM}}{dq^2} \right) (B_s \to \phi \mu^+ \mu^-)_{[1,0,6,0]} = (5.39 \pm 0.66) \times 10^{-8} \text{ GeV}^{-2},
$$

and their experimental values by \cite{44-48}

$$
[R_{K^*}^\text{exp}]_{[1,1,6,0]} = 0.68 \pm 0.12, \\
\text{BR}^\text{exp} (B_s \to \mu^+ \mu^-) = (2.88 \pm 0.42) \times 10^{-9}, \tag{4.15}
$$

$$
\left( \frac{d\text{BR}^\text{exp}}{dq^2} \right) (B_s \to \phi \mu^+ \mu^-)_{[1,0,6,0]} = (2.57 \pm 0.37) \times 10^{-8} \text{ GeV}^{-2}.
$$

The results from these constraints are shown in figure 6. The cyan shaded area corresponds to the allowed region of the real-valued Wilson coefficients $[C_{2222}^{(1)}]$ and $[C_{2223}^{(1)}]$.
Figure 6. Allowed 1- and 2σ contours of the Wilson coefficients \( [C^{(1)}_{\ell q}]_{2222} \) and \( [C^{(1)}_{\ell q}]_{2223} \), subject to the observables \( \Delta R_K, [1, 6], BR(B_s \to \mu^+ \mu^-) \) and \( \langle \Delta f \rangle(B_s \to \phi \mu^+ \mu^-) \). The cyan and grey areas are the allowed regions when RGE evolution or RGE + back-rotation are taken into account, respectively. The Wilson coefficients are assumed to be generated at the NP scale \( \Lambda = 3 \text{ TeV} \).

\[
\begin{align*}
\text{Figure 7.} & \quad \text{Diagrams describing the RGE mixing of the down-type dipole operators } Q_{dX} \text{ with } X = B, W, G, \text{ due to up-type Yukawa interactions in SMEFT. Shown are the quark self-energy contribution (left) and the genuine vertex correction (right).}
\end{align*}
\]

\( \Lambda = 3 \text{ TeV} \), when only the RGE evolution is considered. For the grey region, also back-rotation is taken into account. Examining table 4 one finds, that back-rotation gives an effect which is about one order of magnitude larger than RGE running, which explains the large difference between the cyan and grey region in figure 6. Similar results for these observables, although for different Wilson coefficients, have been obtained in [49].

4.3 \( \psi^2 X \phi \) operators

As a next example we consider the SMEFT dipole operators contributing to the flavour transition \( b \to s\gamma \). We adopt the following effective Lagrangian:

\[
\mathcal{L}^{b \to s\gamma}_{\text{dipole}} = \mathcal{N} \left( C_{7\gamma} \frac{e}{16\pi^2} (\bar{s} \sigma^{\mu\nu} P_R b) F_{\mu\nu} + C_{7'\gamma} \frac{e}{16\pi^2} (\bar{s} \sigma^{\mu\nu} P_L b) F_{\mu\nu} \right) + C_{8g} \frac{g_s}{16\pi^2} (\bar{s} \sigma^{\mu\nu} P_R T^A b) G_{\mu\nu}^A + C_{8's} \frac{g_s}{16\pi^2} (\bar{s} \sigma^{\mu\nu} P_L T^A b) G_{\mu\nu}^A \right),
\]

\( 4.16 \)
where $T^A$ are the SU(3)$_c$ generators and $F_{\mu\nu}$ and $G^A_{\mu\nu}$ are the field-strength tensors of QED and QCD. The tree-level SMEFT matching onto the dipole operators is given by [8]

$$
C_{\gamma\gamma} = \frac{\mu^{2}}{N_C} \left( -[C_{dW}^{*}]_{23} \sin \theta_W + [C_{dB}]_{23} \cos \theta_W \right), \tag{4.17}
$$

$$
C_{\gamma\gamma} = \frac{\mu^{2}}{N_C} \left( -[C_{dW}]_{32} \sin \theta_W + [C_{dB}^{*}]_{32} \cos \theta_W \right), \tag{4.18}
$$

$$
C_{8g} = \frac{\mu^{2}}{N_C g_s} [C_{dg}]_{23}, \quad C_{8'}g = \frac{\mu^{2}}{N_C g_s} [C_{dg}^{*}]_{32}, \tag{4.19}
$$

where $\theta_W$ denotes the Weinberg angle. Focusing on the flavour-diagonal case with flavour indices 22, the contributions to the relevant operators coming from back-rotation and LL running read for the indices 23:

$$
[C_{dW}]_{23}^{(\mu_{EW})} \approx (U_{dR})_{23} \cdot (\tilde{C}_{dW})_{22}^{(\mu_{EW})}, \tag{4.20}
$$

$$
[C_{dB}]_{23}^{(\mu_{EW})} \approx (U_{dR})_{23} \cdot (\tilde{C}_{dB})_{22}^{(\mu_{EW})}, \tag{4.21}
$$

$$
[C_{dg}]_{23}^{(\mu_{EW})} \approx (U_{dR})_{23} \cdot (\tilde{C}_{dg})_{22}^{(\mu_{EW})}, \tag{4.22}
$$

and for the indices 32:

$$
[C_{dW}]_{32}^{(\mu_{EW})} \approx (U_{dR})_{32} \cdot (\tilde{C}_{dW})_{22}^{(\mu_{EW})} + \frac{5g_s^2 V_{tb}^* V_{ts}}{32 \pi^2} [C_{dW}]_{22}^{(\mu_{EW})} \ln \left( \frac{\mu_{EW}}{\Lambda} \right), \tag{4.23}
$$

$$
[C_{dB}]_{32}^{(\mu_{EW})} \approx (U_{dR})_{32} \cdot (\tilde{C}_{dB})_{22}^{(\mu_{EW})} - \frac{3g_s^2 V_{tb}^* V_{ts}}{32 \pi^2} [C_{dB}]_{22}^{(\mu_{EW})} \ln \left( \frac{\mu_{EW}}{\Lambda} \right), \tag{4.24}
$$

$$
[C_{dg}]_{32}^{(\mu_{EW})} \approx (U_{dR})_{32} \cdot (\tilde{C}_{dg})_{22}^{(\mu_{EW})} - \frac{3g_s^2 V_{tb}^* V_{ts}}{32 \pi^2} [C_{dg}]_{22}^{(\mu_{EW})} \ln \left( \frac{\mu_{EW}}{\Lambda} \right), \tag{4.25}
$$

where the diagrams describing operator mixing are given in figure 7. We note that the Wilson coefficients $C_{\gamma\gamma}$ and $C_{8g}$ are only generated through back-rotation, whereas their primed versions receive an additional LL contribution. To study the impact of $[C_{dX}]_{22}$, (with $X = B, W, G$) on $b \to s\gamma$ we impose the observables $\text{BR}(B \to X_s\gamma)$ and the mixing-induced CP asymmetry $S_{K^*\gamma}$. Their SM predictions are given by [50]:

$$
\text{BR}(B \to X_s\gamma)^{\text{SM}} = (3.29 \pm 0.22) \times 10^{-4}, \quad S_{K^*\gamma}^{\text{SM}} = (-2.3 \pm 1.5) \times 10^{-2}, \tag{4.26}
$$

and their experimental values by [42]

$$
\text{BR}(B \to X_s\gamma)^{\text{exp}} = (3.27 \pm 0.14) \times 10^{-4}, \quad S_{K^*\gamma}^{\text{exp}} = -0.16 \pm 0.22. \tag{4.27}
$$

In figure 8 the 2$\sigma$ contours for $[C_{dB}]_{22}$ and $[C_{dg}]_{22}$ are shown. The blue shaded area corresponds to the case where only the running is taken into account and the red area includes the back-rotation to the down-basis. From tables 8 and 10 we see, that the back-rotation factor acts constructively to the RGE effect and therefore enhances the bound on the Wilson coefficients, which is reflected in the difference between the blue and red shaded areas. For $[C_{dg}]_{32}$ the contribution to the observables results mainly from the large QCD mixing from $C_8$ into $C_7$ below the EW scale [39, 51, 52]. The situation is reversed

---

*Similar comments apply to the case with flavour indices 33.*
when complex values for $[C_{dW}]_{22}$ are considered. Here, the sign of the RGE contribution is opposite to the back-rotation part, as seen in eq. (4.23). This leads to the situation depicted in figure 9, where the allowed region for RGE only (blue) is smaller than the one which includes also back-rotation (red). In this case, as opposed to the previous examples, neglecting back-rotation would not lead to an over- but to an underestimation of the allowed values of the Wilson coefficient.

### 4.4 $\psi^2 \varphi^2 D$ operators

In this subsection we study back-rotation effects for operators of the class $\psi^2 \varphi^2 D$. After EW symmetry breaking these operators can induce FC quark couplings of the $Z$ which are defined by

$$\mathcal{L}^{\text{NP}}_{\psi\varphi Z} = Z_\mu \sum_{\psi = u, d} \bar{\psi}_i \gamma^\mu \left( [\Delta^\psi_L(Z)]_{ij} P_L + [\Delta^\psi_R(Z)]_{ij} P_R \right) \psi_j + \text{h.c.} ,$$

with $\psi = u, d$. The down-type couplings can be expressed in terms of SMEFT Wilson coefficients as [30]

$$[\Delta^\psi_L(Z)]_{ij} = -\frac{g_Z}{2} \frac{v^2}{\Lambda^2} \left[ C^{(1)}_{\varphi q} + C^{(3)}_{\varphi q} \right]_{ij} , \quad [\Delta^\psi_R(Z)]_{ij} = -\frac{g_Z}{2} \frac{v^2}{\Lambda^2} [C_{\varphi d}]_{ij} ,$$

with $g_Z = \sqrt{g^2 + g'^2}$ and $v = 246$ GeV is the EW vacuum expectation value. Such operators are however in general strongly constrained by EW precision (EWP) tests, and we will see that the effect from back-rotation and RG running on the flavour observables is shadowed in this case. As an example we discuss the Wilson coefficient $[C^{(1)}_{\varphi q}]_{23}$. Its contributions from back-rotation and LL running at the EW scale are given by
Figure 9. Allowed 1- and 2σ contours for the real and imaginary parts of the Wilson coefficient $[C_{dW}]_{22}$, subject to the $b \rightarrow s$ observables $\text{BR}(B \rightarrow X_s \gamma)$ and the CP asymmetry $S_{K^+\gamma}$. The blue and red areas are the allowed regions when RGE evolution or RGE + back-rotation are taken into account, respectively. The Wilson coefficient is assumed to be generated at the NP scale $\Lambda = 3 \text{ TeV}$.

Figure 10. Feynman diagrams describing the Yukawa mixing of $[C_{q\bar{q}}]^{(1)}_{22}$ into $[C_{q\bar{q}}]^{(1)}_{23}$. The first diagram results from wave function renormalization and the second one is a genuine vertex correction. Similar diagrams are found for the index combination 33.

$$
[C_{q\bar{q}}]^{(1)}_{23}(\mu_{\text{EW}}) \approx (U_{dL})_{23}[\tilde{C}_{q\bar{q}}]^{(1)}_{22}(\mu_{\text{EW}}) + (U_{dL}^\dagger)_{23}[\tilde{C}_{q\bar{q}}]^{(1)}_{33}(\mu_{\text{EW}}) + \frac{y_t^2 V_{ts} V_{tb}}{8\pi^2} \left( [C_{q\bar{q}}]^{(1)}_{22}(\Lambda) + [C_{q\bar{q}}]^{(1)}_{33}(\Lambda) \right) \ln \left( \frac{\mu_{\text{EW}}}{\Lambda} \right),
$$

where the full list of contributions from back-rotation and LL running is given in table 11. The diagrams describing the Yukawa mixing in the second line of eq. (4.30) are depicted in figure 10. Imposing now $b \rightarrow s\ell\ell$ as well as EWP constraints from [14] leads to the contour regions in figure 11.

The cyan and black contours are obtained from $b \rightarrow s\ell\ell$ observables when RGE running and RGE + back-rotation are taken into account, respectively. Again, back-rotation has a large effect on the allowed region of the corresponding Wilson coefficients. However, constraints from EWP, depicted by the small magenta region in figure 11, are much stronger and have a preference for a slightly different region in parameter space. Therefore, the Wilson coefficients $[C_{q\bar{q}}]^{(1)}_{22}$ and $[C_{q\bar{q}}]^{(1)}_{33}$ alone are insufficient to explain the $b \rightarrow s\ell\ell$ data.
5 Conclusions

In this article we investigate Yukawa RGE effects in the SMEFT and their impact on down-type flavour observables. We identify the two leading effects on the SMEFT Wilson coefficients resulting from Yukawa running, namely the standard RGE evolution of the Wilson coefficients and secondly effects due to the flavour rotation back to the down-basis. The latter results from Yukawa diagonalization at the EW scale and can have sizable effects comparable or even surpassing the ones from mere RG running. We compare this back-rotation to the RGE evolution using numerous examples. For instance, we consider vector operators contributing to $\Delta B = \Delta S = 2$ processes and find that back-rotation largely reduces the allowed regions of the Wilson coefficients. Furthermore we study dipole operators in the context of $b \to s\ell\ell$ observables and show, that back-rotation can lead to either an under- or an overestimation of the resulting Wilson coefficient bounds. Finally, for semi-leptonic SMEFT Wilson coefficients, their bounds from $b \to s\ell\ell$ processes change completely when taking back-rotation into account. From these results we conclude, that back-rotation effects are an integral part of down-type flavour SMEFT analyses and need to be included to obtain a fully consistent picture. The effect is most pronounced when a flavour rotation is performed on one single flavour index. In the case of multiple rotations the impact is suppressed by small entries of the rotation matrices. Furthermore, there are examples where back-rotation provides only a sub-dominant effect. This is for instance the case for $\psi^2\phi^2 D$ operators, which are strongly constrained from EW precision tests.

In our numerical analysis we worked in the Warsaw-down basis at the NP scale $\Lambda = 3 \text{ TeV}$. Changing this assumption by adopting a different basis at the high scale corresponds to a
linear transformation of the initial conditions and would therefore lead to a simple scaling of the results. The conclusions would however remain the same. In principle, such back-rotation effects can also occur when studying up-type flavour observables. However, we leave an explicit analysis for the future. Finally, the back-rotation effect was studied in the context of Kaon decays in [38] and has been found to be sizable for QCD penguin operators.

A large contribution to $\varepsilon'/\varepsilon$ is excluded when the constraint from $\varepsilon_K$ is taken into account, since back-rotation provides a large CP violating contribution to these operators which then violate the constraints from $\varepsilon_K$.

A Yukawa anomalous dimensions

In this appendix we report the full RG equations of the Yukawa couplings in SMEFT. The $\beta$-functions of the up-, down-type and lepton Yukawa matrices are given by [12, 53]

$$[\beta_{Y_u}]_{rs} = \frac{3}{2} \left( [Y_u Y_u^t Y_u]_{rs} - [Y_u Y_d^t Y_u]_{rs} \right) + \left( \gamma_H^{(Y)} - \frac{9}{4} g^2 - \frac{17}{12} g'^2 - 8 g_s^2 \right) [Y_u]_{rs}$$

$$+ 2 \frac{m^2}{\Lambda^2} \left[ 3 [C_{\varphi'}]_{rs} + \frac{1}{2} (C_{\varphi D} - 2 C_{\varphi C}) [Y_u]_{rs} - \left[ C_{\varphi q}^{(1)} [Y_u]_{rs} + \frac{4}{3} \left[ C_{\varphi q}^{(8)} \right]_{rpts} [Y_u]^*_{pt} \right] \right] + [Y_u C_{\varphi u}^{*}]_{rs} - [Y_d C_{\varphi ud}^{*}]_{rs} - 2 \left( \left[ C_{\varphi q}^{(1)} ]_{rpts} + \frac{4}{3} \left[ C_{\varphi q}^{(8)} \right]_{rpts} \right] [Y_u]^*_{pt} - \left[ C_{\varphi q}^{(1)} ]_{rpts} [Y_u]^*_{pt} \right] \right] + 3 \left[ C_{\varphi q}^{(1)} ]_{rpts} [Y_u]^*_{pt} + \frac{1}{2} \left( \left[ C_{\varphi q}^{(1)} ]_{rpts} + \frac{4}{3} \left[ C_{\varphi q}^{(8)} \right]_{rpts} \right] [Y_u]^*_{pt} \right] \right]$$

$$[\beta_{Y_d}]_{rs} = \frac{3}{2} \left( [Y_d Y_d^t Y_d]_{rs} - [Y_d Y_u^t Y_d]_{rs} \right) + \left( \gamma_H^{(Y)} - \frac{9}{4} g^2 - \frac{5}{12} g'^2 - 8 g_s^2 \right) [Y_d]_{rs}$$

$$+ 2 \frac{m^2}{\Lambda^2} \left[ 3 [C_{\varphi'}]_{rs} + \frac{1}{2} (C_{\varphi D} - 2 C_{\varphi C}) [Y_d]_{rs} + \left[ C_{\varphi q}^{(1)} [Y_d]_{rs} + \frac{4}{3} \left[ C_{\varphi q}^{(8)} \right]_{rpts} [Y_d]^*_{pt} \right] \right] - [Y_d C_{\varphi d}^{*}]_{rs} - [Y_u C_{\varphi ud}^{*}]_{rs} - 2 \left( \left[ C_{\varphi q}^{(1)} ]_{rpts} + \frac{4}{3} \left[ C_{\varphi q}^{(8)} \right]_{rpts} \right] [Y_d]^*_{pt} + \left[ C_{\varphi q}^{(1)} ]_{rpts} [Y_d]^*_{pt} \right] \right] + 3 \left[ C_{\varphi q}^{(1)} ]_{rpts} [Y_d]^*_{pt} + \frac{1}{2} \left( \left[ C_{\varphi q}^{(1)} ]_{rpts} + \frac{4}{3} \left[ C_{\varphi q}^{(8)} \right]_{rpts} \right] [Y_d]^*_{pt} \right] \right]$$

$$[\beta_{Y_e}]_{rs} = \frac{3}{2} \left( [Y_e Y_e^t Y_e]_{rs} \right) + \left( \gamma_H^{(Y)} - \frac{3}{4} (3 g^2 + 5 g'^2) \right) [Y_e]_{rs}$$

$$+ 2 \frac{m^2}{\Lambda^2} \left[ 3 [C_{\varphi'}]_{rs} + \frac{1}{2} (C_{\varphi D} - 2 C_{\varphi C}) [Y_e]_{rs} + \left[ C_{\varphi \ell}^{(1)} [Y_e]_{rs} + \frac{4}{3} \left[ C_{\varphi \ell}^{(8)} \right]_{rpts} [Y_e]^*_{pt} \right] \right] - [Y_e C_{\varphi e}^{*}]_{rs} - 2 \left[ C_{\varphi \ell}^{*} rpts [Y_e]^*_{pt} + \left[ C_{\varphi \ell}^{(1)} ]_{rpts} [Y_e]^*_{pt} \right] \right] + 3 \left[ C_{\varphi \ell}^{(1)} ]_{rpts} [Y_e]^*_{pt} \right] , \quad (A.3)$$

\[\varepsilon_K\]
with the $SU(3)_c \times SU(2)_L \times U(1)_Y$ gauge couplings $g_s$, $g$ and $g'$, the Higgs mass parameter $m$ and the wave function normalization

$$\gamma^{(Y)}_H = \text{Tr} \left( 3 Y_u Y_u^\dagger + 3 Y_d Y_d^\dagger + Y_e Y_e^\dagger \right).$$

(A.4)

## B Back-rotation and RG running

In this appendix we report the individual contributions to the SMEFT operators at the EW scale, resulting from back-rotation and LL Yukawa running of Wilson coefficients as discussed in section 4. Each table lists the contributions to a certain operator resulting from different flavour indices of that same operator.

### B.1 (LL)(RR) operators

| index $ijkl$ of $[C^{(1)}_{qd}]_{ijkl}$ | back-rotation | LL running |
|--------------------------------------|----------------|------------|
| 2323                                 | $1.0 + (2.4 \cdot 10^{-5}) \, i$ | 0.99 |
| 1323                                 | $-1.4 \cdot 10^{-5} + (6.9 \cdot 10^{-6}) \, i$ | $3.9 \cdot 10^{-6} - (1.6 \cdot 10^{-6}) \, i$ |
| 3323                                 | $1.7 \cdot 10^{-3} - (3.2 \cdot 10^{-5}) \, i$ | $4.5 \cdot 10^{-4} - (8.7 \cdot 10^{-6}) \, i$ |
| 2123                                 | $3.5 \cdot 10^{-4} + (1.4 \cdot 10^{-4}) \, i$ | $-9.2 \cdot 10^{-5} - (3.8 \cdot 10^{-5}) \, i$ |
| 2223                                 | $-1.7 \cdot 10^{-3} + (3.2 \cdot 10^{-5}) \, i$ | $4.5 \cdot 10^{-4} - (8.7 \cdot 10^{-6}) \, i$ |
| 2313                                 | $-1.4 \cdot 10^{-6} + (6.0 \cdot 10^{-7}) \, i$ | 0 |
| 2333                                 | $6.7 \cdot 10^{-5} - (1.3 \cdot 10^{-6}) \, i$ | 0 |
| 2321                                 | $6.7 \cdot 10^{-7} + (2.7 \cdot 10^{-7}) \, i$ | 0 |
| 2322                                 | $-6.7 \cdot 10^{-5} + (1.3 \cdot 10^{-6}) \, i$ | 0 |

Table 2. Back-rotation and LL effect for $[C^{(1)}_{qd}]_{2323}$ at the EW scale. The same table is obtained when considering the Wilson coefficient $[C^{(8)}_{qd}]_{2323}$. 

- 18 -
B.2 (LL)(LL) operators

| index $ijkl$ of $[C^{(1)}_{qq}]_{ijkl}$ | back-rotation | LL running |
|--------------------------------------|----------------|------------|
| 2323                                 | $1.0 + (2.4 \cdot 10^{-5}) i$ | 0.98       |
| 1323                                 | $-1.4 \cdot 10^{-5} + (6.0 \cdot 10^{-6}) i$ | $7.7 \cdot 10^{-6} - (3.2 \cdot 10^{-6}) i$ |
| 3323                                 | $1.7 \cdot 10^{-3} - (3.2 \cdot 10^{-5}) i$ | $9.0 \cdot 10^{-4} - (1.7 \cdot 10^{-5}) i$ |
| 2123                                 | $3.5 \cdot 10^{-4} + (1.4 \cdot 10^{-4}) i$ | $-1.8 \cdot 10^{-4} - (7.5 \cdot 10^{-5}) i$ |
| 2223                                 | $-1.7 \cdot 10^{-3} + (3.2 \cdot 10^{-5}) i$ | $9.0 \cdot 10^{-4} - (1.7 \cdot 10^{-5}) i$ |
| 2313                                 | $-1.4 \cdot 10^{-5} + (6.0 \cdot 10^{-6}) i$ | 0          |
| 2333                                 | $1.7 \cdot 10^{-3} - (3.2 \cdot 10^{-5}) i$ | 0          |
| 2321                                 | $3.5 \cdot 10^{-4} + (1.4 \cdot 10^{-4}) i$ | 0          |
| 2322                                 | $-1.7 \cdot 10^{-3} + (3.2 \cdot 10^{-5}) i$ | 0          |

**Table 3.** Back-rotation and LL effect for $[C^{(1)}_{qq}]_{2323}$ at the EW scale. The same table is obtained when considering the Wilson coefficient $[C^{(3)}_{qq}]_{2323}$.

| index $ijkl$ of $[C^{(1)}_{eq}]_{ijkl}$ | back-rotation | LL running |
|--------------------------------------|----------------|------------|
| 2223                                 | $1.0 + (1.2 \cdot 10^{-5}) i$ | 0.99       |
| 2213                                 | $-1.4 \cdot 10^{-5} + (6.0 \cdot 10^{-6}) i$ | $3.9 \cdot 10^{-6} - (1.6 \cdot 10^{-6}) i$ |
| 2233                                 | $1.7 \cdot 10^{-3} - (3.2 \cdot 10^{-5}) i$ | $4.5 \cdot 10^{-4} - (8.7 \cdot 10^{-6}) i$ |
| 2221                                 | $3.5 \cdot 10^{-4} + (1.4 \cdot 10^{-4}) i$ | $-9.2 \cdot 10^{-5} - (3.8 \cdot 10^{-5}) i$ |
| 2222                                 | $-1.7 \cdot 10^{-3} + (3.2 \cdot 10^{-5}) i$ | $4.5 \cdot 10^{-4} - (8.7 \cdot 10^{-6}) i$ |
