Abstract

New corrections to the energy of S-levels of positronium of order $m\alpha^6$ which are as large as several hundred kilohertz are obtained. A new recoil correction of order $\alpha(Z\alpha)^5(m/M)m$ to the Lamb shift in hydrogen is calculated. This correction turns out to be too small from the phenomenological point of view.
1. Recent progress in the spectroscopy of positronium triggered theoretical work on the corrections of order $\alpha^6 m$ to the positronium energy levels. All logarithmic corrections of this order to $S$-levels were calculated recently in \cite{3,7}. Complete results for the corrections of order $\alpha^6 m$ to $P$-levels were obtained in \cite{8}. As emphasized in this last work the large magnitude of the nonlogarithmic corrections to $P$-levels suggest that calculation of corresponding nonlogarithmic corrections to $S$-levels is also important. Some of these corrections are already known, e.g., contributions induced by the two- and three-photon annihilation kernels \cite{11,10,9}. We present below results of the calculation of nonlogarithmic contributions of order $\alpha^6 m$ to the $S$-levels of positronium induced by radiative corrections to the Breit potential and by the polarization insertions in the graphs with two-photon exchange.

A new radiative-recoil correction of order $\alpha(Z\alpha)^5(m/M)m$ to the Lamb shift in hydrogen induced by a polarization operator insertion in the two-photon exchange graph is also calculated in this note. Recent experimental achievements in measuring $1S - 2S$ splitting in hydrogen \cite{12} and the well-known results on the $2S$ Lamb shift \cite{13,14,15} clearly demonstrate that theoretical calculation of all corrections to the Lamb shift of the order of several kHz for the $1S$-state and about 1 kHz for the $2S$-state is necessary. Several such contributions were obtained quite recently \cite{16,17,18} and the result presented below is one more such contribution (for more detailed description of the current theoretical status of the Lamb shift calculations see, e.g. \cite{19}).

2. Let us consider first corrections of order $\alpha^6 m$ to the $S$-levels of positronium connected with radiative insertions in the graph with one-photon exchange in Fig 1. As is well known this graph leads to the Breit potential. One may easily obtain the radiatively corrected expression for the Breit potential in the form\footnote{The annihilation diagram contribution is missing in this expression since we do not consider annihilation contributions in this paper.} (see, e.g. \cite{20} and paper in preparation)

\[
U(p, r) = -\alpha \left\{ \frac{1}{r} - \pi \frac{1 + 8 f_1^2 + 2 f_2}{m^2 c^2} \delta^3(r) + \frac{4 \pi p}{m^2 c^2} \frac{s l}{r^3} \right\} + \frac{r(rp) p}{2 m^2 c^2 r^3} + \frac{p^2}{2 m^2 c^2 r} - (3 + 4 f_2) \frac{s l}{2 m^2 c^2 r^3}
\]
+ \frac{(1 + f_2)^2}{4m^2c^2} \left\{ s_i, s_j \left( \frac{\delta_{ij}}{r^3} - 3 \frac{r_i r_j}{r^5} \right) - \frac{(1 + f_2)^2 \pi}{m^2c^2} \left( \frac{4}{3} \delta^2 - 2 \right) \delta^3(r) \right\},

where $m$ is the electron mass, $p$ is the relative momentum of the electron and positron, $r$ is their relative position, $f'_1$ is the slope of the Dirac formfactor, $f_2$ is the Pauli formfactor at zero momentum transfer and $p$ is the polarization operator contribution. With two-loop accuracy we have

\begin{align*}
  f'_1 &= \frac{e_1}{m^2} \frac{\alpha}{\pi} + \frac{e_2}{m^2} \left( \frac{\alpha}{\pi} \right)^2, \\
  f_2 &= g_1 \frac{\alpha}{\pi} + g_2 \left( \frac{\alpha}{\pi} \right)^2, \\
  p &= p_1 \frac{\alpha}{\pi} + p_2 \left( \frac{\alpha}{\pi} \right)^2.
\end{align*}

It is an easy task now to obtain corrections of order $\alpha^6 m$ to the positronium energy levels

\begin{align*}
  \Delta E_{F_1} &= e_2 \alpha^6 \frac{m \delta_{l0}}{2 \pi^2 n^3} = 0.469 \, 94 \, \alpha^6 \frac{m \delta_{l0}}{2 \pi^2 n^3}, \\
  \Delta E_{F_2,|l=0} &= g_2 \frac{\alpha^4 m}{4n^3} = -0.082 \, \alpha^6 \frac{m}{2 \pi^2 n^3}, \\
  \Delta E_{p2} &= -p_2 \frac{\alpha^6}{2 \pi^2 n^3} m \delta_{l0} = -\frac{41}{324} \alpha^6 \frac{m \delta_{l0}}{2 \pi^2 n^3},
\end{align*}

where we used the value of the two-loop contribution $e_2$ to the slope of the Dirac formfactor obtained numerically in [21] and analytically in [22], the explicit results for the two-loop electron magnetic moment $g_2$ [23, 24], and the two-loop irreducible vacuum polarization operator [25] obtained a long time ago.

With the help of the effective potential in eq.(1) we may also easily calculate radiative corrections to the levels of positronium which have nonvanishing angular momentum. Our results in this case reproduce and confirm the respective results in [8, 15].

3. Consider now corrections of relative order $\alpha^6$ to the energy levels of two-body systems which are generated by the diagrams with intermediate momenta which are high on the scale of the typical atomic momenta. It is well known that all such corrections are generated by the diagrams with two exchanged photons containing also either a polarization operator insertion in one of the exchanged photons or radiative photon insertions in the electron
line (see, e.g. [26]). To sufficient accuracy external electron lines in the
diagrams under consideration may be safely taken to be on-mass shell. It
is not difficult to obtain an explicit expression for the infrared divergent
skeleton integral corresponding to the sum of ladder and crossed diagrams
in Fig.2. Direct integration over loop momentum advocated in [27] leads to
the following expression for the skeleton integral

$$\Delta E_{\text{skeleton}} = -32mM(Z\alpha)^2|\psi(0)|^2$$

\[
\int_0^\infty \frac{dk}{\pi k} \int_0^\pi d\theta \frac{\sin^2 \theta (1 + 2 \cos^2 \theta)}{(k^2 + 4m^2 \cos^2 \theta)(k^2 + 4M^2 \cos^2 \theta)}
\]

\[
= -16mM(Z\alpha)^2|\psi(0)|^2 \int_0^\infty \frac{dk}{k^3 (m^2 - M^2)} \left\{ m\sqrt{1 + \frac{k^2}{4m^2} \left( \frac{1}{k} + \frac{k^3}{8m^4} \right)} - M\sqrt{1 + \frac{k^2}{4M^2} \left( \frac{1}{k} + \frac{k^3}{8M^4} \right)} \right\},
\]

where \( m \) and \( M \) are the masses of the negatively and positively charged
particles, respectively, \( Z \) is the charge of the positive particle in terms of the
proton charge and \( \psi(0) \) is the value of the reduced mass Schrödinger-Coulomb
wave function at the origin.

All contributions to hydrogen Lamb shift of order \( \alpha(Z\alpha)^5m \), both recoil
and nonrecoil, calculated over years by different methods [28, 29, 30], may be
obtained from the expression for the skeleton integral in eq.(4) by insertion
of radiative corrections.

Consider first recoil contributions of order \( \alpha(Z\alpha)^5m \) to the Lamb shift
in hydrogen. The contribution induced by the radiative photon insertions
in the electron line was obtained in [31]. With the help of explicit expression in
eqn.(4) above, it is easy to confirm the result of [31] that correction induced by
the radiative photon insertions in the heavy line is suppressed by the factor \( (m/M)^2 \)
relative to the contribution induced by the radiative photon
insertion in the electron line. It is also easy to see that the recoil correction
corresponding to the polarization operator insertion in the exchanged photon
is suppressed by the factor \( m/M \) relative to respective nonrecoil correction.
Let us calculate this last correction. The general expression in eq.(4) contains
the skeleton integral both for recoil and nonrecoil corrections. The skeleton
integral for the recoil corrections may be obtained by subtracting the heavy
pole residue in eq.(4) and has the form
\[ \Delta E_{\text{ske}l-rec} = \frac{16(Z\alpha)^2|\psi(0)|^2}{m^2(1 - \mu^2)} \int_0^\infty \frac{kdk}{(k^2 + \lambda^2)^2} \left\{ \mu \sqrt{1 + \frac{k^2}{4} \left( \frac{1}{k} + \frac{k^3}{8} \right)} \right\} \]

\[ -\sqrt{1 + \frac{\mu^2k^2}{4} \left( \frac{1}{k} + \frac{\mu^4k^3}{8} \right)} - \frac{\mu k^2}{8} \left( 1 + \frac{k^2}{2} \right) + \frac{\mu^3k^2}{8} \left( 1 + \frac{\mu^2k^2}{2} \right) + \frac{1}{k} \}, \]

where \( \mu = m/M, \lambda \) is an auxiliary mass of the exchanged photon which is omitted below, and we transferred to a dimensionless integration momentum measured in units of the electron mass.

For calculation of the radiative-recoil contribution to the Lamb shift induced by the polarization operator insertions one has to make a substitution in the integrand in eq.(5)

\[ \frac{1}{k^2} \rightarrow \frac{\alpha}{\pi} I_1(k), \]

where

\[ I_1(k) = \int_0^1 dv \frac{v^2(1 - v^2/3)}{4 + (1 - v^2)k^2}. \]

However, the skeleton integrand in eq.(5) behaves as \( \mu/k^4 \) at small momenta and naive substitution in eq.(6) leads to divergence. This divergence \( dk/k^2 \) actually diminishes the power of the \( Z\alpha \) factor and the respective contribution turns out to be of order \( \alpha(Z\alpha)^4 \). In order to get the recoil correction of order \( \alpha(Z\alpha)^5m \) we have to subtract the leading low frequency asymptote of the product of the skeleton integrand and the polarization operator. Then we obtain the integral for the radiative-recoil correction (one has to insert an additional factor of 2 which takes into account possible insertions of the polarization in both photon lines)

\[ \Delta E_r = \frac{32(Z\alpha)^2|\psi(0)|^2}{m^2(1 - \mu^2)} \left( \frac{\alpha}{\pi} \right) \int_0^\infty \frac{dk}{k} I_1(k) \left[ \mu \sqrt{1 + \frac{k^2}{4} \left( \frac{1}{k} + \frac{k^3}{8} \right)} \right] \]

\[ -\sqrt{1 + \frac{\mu^2k^2}{4} \left( \frac{1}{k} + \frac{\mu^4k^3}{8} \right)} - \frac{\mu k^2}{8} \left( 1 + \frac{k^2}{2} \right) + \frac{\mu^3k^2}{8} \left( 1 + \frac{\mu^2k^2}{2} \right) + \frac{1}{k} \} - \frac{\mu}{15k}]. \]
This integral contains also some contributions of higher order in the electron-proton mass ratio and may be easily calculated numerically. However, these higher order contributions are clearly negligible and we omit them. Then we obtain the analytic result

$$
\Delta E_r = \left( \frac{2\pi^2}{9} - \frac{70}{27} \right) \mu \frac{\alpha(Z\alpha)^5 m}{\pi^2 n^3} \left( \frac{m_e}{m} \right)^3.
$$

(9)

4. Consider now the contribution of order $\alpha^6$ induced by insertion of the one-loop polarization operator for the positronium case. Calculation is similar to the one for hydrogen. The analog of the skeleton integral in eq.(4), for the case of equal masses, has the form

$$
\Delta E = -16m^2(Z\alpha)^2|\psi(0)|^2 \int_0^\infty \frac{dk}{k^4} \left\{ \frac{1}{\sqrt{k^2 + 4m^2}} \right. \\
+ \frac{k^3}{8m^4} - \frac{k^4(k^2 + 3m^2)}{8m^6\sqrt{k^2 + 4m^2}} + \frac{k^5}{8m^6} \right\}
$$

= $-\frac{2\alpha^5 m^5}{\pi n^3} \int_0^\infty \frac{dk}{k^4} \left\{ \frac{1}{\sqrt{k^2 + 4m^2}} \\
+ \frac{k^3}{8m^4} - \frac{k^4(k^2 + 3m^2)}{8m^6\sqrt{k^2 + 4m^2}} + \frac{k^5}{8m^6} \right\}.
$$

(10)

Consideration of the hydrogen case above teaches us that the integrand for the radiative correction is given by the subtracted product of the vacuum polarization operator and the skeleton integrand. Hence, contribution to the energy levels of positronium of order $m\alpha^6$ is given by the expression (remember combinatorial factor 2)

$$
\Delta E_{p1} = \frac{-4\alpha^6 m^5}{\pi^2 n^3} \int_0^\infty \frac{dk}{k^2} \left\{ I_1(k) \left[ \frac{1}{\sqrt{k^2 + 4m^2}} + \frac{k^3}{8m^4} - \frac{k^4(k^2 + 3m^2)}{8m^6\sqrt{k^2 + 4m^2}} \right] \\
+ \frac{k^5}{8m^6} \right\} - \frac{1}{30} = \left( \frac{\pi^2}{36} - \frac{5}{27} \right) \frac{m\alpha^6}{\pi^2 n^3}.
$$

(11)

5. Numerical values of the corrections obtained above are presented in the Table.
In the case of positronium these corrections turn out to be of the same order of magnitude as other corrections to the energy levels calculated recently \([6, 7, 8, 9, 10, 11]\) and are significant for comparison of the theory with the current experimental results. In the case of hydrogen the corrections for the \(S\)-levels obtained above are about an order of magnitude smaller than the corrections of order \(\alpha^6(m/M)m\) for the \(P\)-levels obtained recently \([18]\) and are too small to be interesting from the phenomenological point of view. Detailed derivation of the results of this paper will be presented elsewhere. In the case of positronium there remain some other yet unknown contributions of order \(\alpha^6m\) to the energy shift of \(S\)-levels. Work on their calculation is in progress now.

We are deeply grateful to V. A. Shelyuto and S. G. Karshenboim for attracting our attention to inaccuracy of our subtraction procedure in the preliminary version of this report. We are also deeply grateful to I.B. Khriplovich for a helpful remark on the radiative corrections to the Breit potential and to K. Pachucki for useful communications. This work was done during the visit of M.E. to the Penn State University. He is deeply grateful to the colleagues at the Physics Department of the Penn State University for their kind hospitality. This research was supported by the National Science Foundation under grant \#NSF-PHY-9120102. Work of M.E. was also supported in part by grant \#R2E000 from the International Science Foundation and by the Russian Foundation for Fundamental Research under grant \#93-02-3853.
