Abstract The soft gluon limit of the longitudinal part of the quark-gluon vertex is studied by resorting to non-perturbative approaches to quantum chromodynamics (QCD). Based on a Slavnov–Taylor identity (STI), the longitudinal form factors is expressed in terms of the quark-ghost kernel, the quark self energy and the quark wave function. An exact relation between the non-vanishing longitudinal form factors is derived for the soft gluon limit and explored to understand the behaviour of the vertex. Within a Ball–Chiu vertex, the form factor $\lambda_1$ was analysed using recent lattice simulations for full QCD for the soft gluon limit. The lattice data shows that the gluon propagator resumes the momentum dependence of such component of the vertex. This connection is understood via a fully dressed one-loop Bethe–Salpeter equation. The behaviour of the remaining longitudinal form factors $\lambda_2(p^2)$ and $\lambda_3(p^2)$ is investigated combining both the information of lattice simulations and the derived relations based on the STI.

1 Introduction and motivation

The quark-gluon vertex is at the heart of all hadron phenomena. Quark confinement and dynamical chiral symmetry breaking, two open problems in modern strong interactions, require certainly a good understanding of this one-particle irreducible function. Despite all efforts towards a first principle calculation of the quark-gluon vertex, a complete solution is still lacking. The information on the structure of the vertex is crucial also for the continuous approaches to QCD that, typically, rely on modelling the functional dependence of the form factors associated to its various tensor structures, assume the dominance of one of the form factors, e.g., $\lambda_1(p^2)$ and explore various truncations of the corresponding Dyson–Schwinger and Bethe–Salpeter kernels.

Progress in computing the quark-gluon vertex and the fundamental QCD kernels has been slow and it revealed quite a difficult problem per se [1–16]. In this perspective, gathering information and combining various non-perturbative approaches can be useful to learn more about this fundamental QCD quantity. Efforts along this line has already been pursued in the Landau gauge in [3], where lattice results for the gluon, ghost and quark propagator have been used together with the Slavnov–Taylor Identity (STI) for the quark-gluon vertex to solve the quark gap equation that relates all these quantities and implicitly defines a coupled set of integral equations to be solved for the unknown form factors of the quark-ghost kernel. We remind that the STI allows to express the quark-gluon vertex in terms of the quark-ghost kernel form factors. The solution for the vertex obtained from the gap equation relied on a particular simplification of the full structure tensor of the quark-ghost kernel and, therefore, of the vertex. A similar approach to the gluon-ghost vertex can be found in [17].

In this work, we aim to go further on the above delineated approach studying the soft gluon limit of the quark-gluon vertex provided by full QCD lattice simulations for $N_f = 2$ in combination with the information that the STI adds on. From the STI, that constrains the longitudinal part of the quark-gluon vertex, an exact relation between $\lambda_1$, $\lambda_2$ and $\lambda_3$ is obtained in the soft gluon limit that links these form factors and those associated with the quark-ghost kernel.

Furthermore, relying on the soft gluon limit of the STI for $\lambda_1$, we explore the results from the recent Lattice QCD simulation [18]. In particular, we find an empirical connection linking the gluon propagator $\Delta(p^2)$ and the soft gluon...
limit for $\lambda_1(p^2)$ that writes this form factor, for momenta up to $p \sim 10$ GeV, in terms of $\Delta(p^2)$. As discussed, this connection can be understood in terms of a dressed one-loop Bethe–Salpeter equation for the vertex function. Moreover, the information coming from the STI and the lattice data for $\lambda_1$, allows the understanding of the qualitative behaviour of the remaining non-vanishing longitudinal form factors $\lambda_2$ and $\lambda_3$, in the soft gluon limit.

2 Notation and definitions

For the diagonal metric $g = (1, -1, -1, -1)$ defined in Minkowsky space, the one-particle irreducible Green function associated to the quark-gluon vertex represented on Fig. 1 reads

$$\Gamma_{\mu}(p_1, p_2, p_3) = g^{\mu a} \Gamma_{\mu}(p_1, p_2, p_3), \quad \text{(1)}$$

where all momenta are incoming and, therefore, $p_1 + p_2 + p_3 = 0$. $g$ is the strong coupling constant and $t^a$ are the SU(3) generators in the fundamental representation. Herein we follow the notation of [19].

The quark propagator is color diagonal and has the following Dirac structure

$$S(p) = \frac{i}{A(p^2)\not{p} - B(p^2)} = i Z(p^2) \frac{\not{p} + M(p^2)}{p^2 - M^2(p^2)}, \quad \text{(2)}$$

where $Z(p^2) = 1/A(p^2)$ is the quark wave function and $M(p^2) = B(p^2)/A(p^2)$ is the renormalization group invariant running quark mass. In the Landau gauge, the gluon propagator is given by

$$\Delta_{\mu\nu}^{ab}(q) = -i \delta^{ab} \left( g_{\mu\nu} - \frac{q_\mu q_\nu}{q^2} \right) \Delta(q^2). \quad \text{(3)}$$

In the following, we will refer either to $\Delta_{\mu\nu}^{ab}(q)$ or to the form factor $\Delta(q^2)$ as the gluon propagator.

The Lorentz structure of the quark-gluon vertex $\Gamma_\mu$, see Eq. (1), can be decomposed into longitudinal $\Gamma^{(L)}$ and transverse $\Gamma^{(T)}$ components relative to the gluon momenta as

$$\Gamma_\mu(p_1, p_2, p_3) = \Gamma^{(L)}_\mu(p_1, p_2, p_3) + \Gamma^{(T)}_\mu(p_1, p_2, p_3), \quad \text{(4)}$$

where, by definition,

$$p_3^\mu \Gamma^{(T)}_\mu(p_1, p_2, p_3) = 0. \quad \text{(5)}$$

By choosing a suitable tensor basis in the spinor-Lorentz space, $\Gamma_\mu$ can be written as a sum of scalar form factors that multiply each of the elements of the basis. The full vertex $\Gamma_\mu$ requires twelve form factors and for the Ball and Chiu [20] basis one writes

$$\Gamma^{(L)}_\mu(p_1, p_2, p_3) = -i \sum_{i=1}^{3} \lambda_i(p_1, p_2, p_3) L^{(i)}_\mu(p_1, p_2) \quad \text{(6)}$$

$$\Gamma^{(T)}_\mu(p_1, p_2, p_3) = -i \sum_{i=1}^{3} \tau_i(p_1, p_2, p_3) T^{(i)}_\mu(p_1, p_2). \quad \text{(7)}$$

For the longitudinal vertex studied below, the operators are given by

$$L^{(1)}_\mu(p_1, p_2) = \gamma_\mu, \quad \text{(8)}$$

$$L^{(2)}_\mu(p_1, p_2) = (\not{p}_1 - \not{p}_2) (p_1 - p_2)_\mu, \quad \text{(9)}$$

$$L^{(3)}_\mu(p_1, p_2) = (p_1 - p_2)_\mu \not{D}, \quad \text{(10)}$$

$$L^{(4)}_\mu(p_1, p_2) = \sigma_{\mu\nu} (p_1 - p_2)_{\nu}, \quad \text{(11)}$$

where $\sigma_{\mu\nu} = \frac{i}{2} [\gamma_\mu, \gamma_\nu]$. The transverse operator basis $T^{(i)}_\mu(p_1, p_2)$ can be found in [20].

3 Constraints on the quark-gluon vertex

The global and local symmetries of QCD constraints the full vertex $\Gamma_\mu$ and connect several of the Green’s functions of the theory. For example, the global symmetries of QCD require that the form factors $\lambda_i$ and $\tau_i$ to be either symmetric or anti-symmetric under exchange of the two first momenta – see, e.g., Ref. [19] and references therein. On the other hand, gauge symmetry implies non-trivial relations between the QCD Green’s functions that can be translated into Slavnov-Taylor identities [21,22] that play a major role in our understanding of the theory. In particular, the transverse part of the quark-gluon vertex is constrained, in the Landau gauge, by the following identity

$$p_3^\mu \Gamma^{(T)}_\mu(p_1, p_2, p_3) = F(q^2) \left[ S^{-1}(-p_1) H(p_1, p_2, p_3) - \overline{H}(p_2, p_3) S^{-1}(p_2) \right], \quad \text{(12)}$$

where the ghost-dressing function $F(q^2)$ is related to the ghost two-point correlation function as

$$D^{ab}(q^2) = -\delta^{ab} F(q^2)/q^2 \quad \text{(13)}$$

and $H$ and $\overline{H}$ are associated to the quark-ghost kernel – see [19] for definitions and discussion. The quark-ghost kernel can be parametrized in terms of four form factors.
where $X_i \equiv X_i(p_1, p_2, p_3)$ and $\overline{X}_i \equiv \overline{X}_i(p_2, p_1, p_3)$. The above STI can be solved for the form factors $A(\lambda)$ that can be written in terms of $A(p^2)$, $B(p^2)$, $X_i$ and $\overline{X}_i$ as given in [23]

$$
\lambda_1(p_1, p_2, p_3) = \frac{F(p^2)}{2} \left\{ B(p^2) [X_1 + X_2] \\
+B(p^2) [X_1 - X_2] \\
+A(p^2) \left[ X_0 + (p_1 - p_2) X_3 \right] \\
+A(p^2) \left[ X_0 + (p_2 - p_1) X_3 \right] \right\},
$$

(15)

$$
\lambda_2(p_1, p_2, p_3) = \frac{F(p^2)}{2(p_2 - p_1)} \left\{ B(p^2) [X_2 - X_1] \\
+B(p^2) \left[ X_1 - X_2 \right] \\
+A(p^2) \left[ (p_1 + p_2) X_3 - X_0 \right] \\
+A(p^2) \left[ X_0 - (p_2 + p_1) X_3 \right] \right\},
$$

(16)

$$
\lambda_3(p_1, p_2, p_3) = \frac{F(p^2)}{p_1^2 - p_2^2} \left\{ B(p^2) X_0 \\
-B(p^2) X_0 \\
+A(p^2) \left[ p_2^2 X_1 + p_1^2 X_2 \right] \\
-A(p^2) \left[ p_2^2 X_1 + p_1^2 X_2 \right] \right\},
$$

(17)

$$
\lambda_4(p_1, p_2, p_3) = \frac{F(p^2)}{2} \left\{ B(p^2) X_3 - B(p^2) X_3 \\
+A(p^2) X_2 - A(p^2) X_2 \right\}.
$$

(18)

By direct inspection one can show straightforwardly that the solution given in Eqs. (15)–(18) for the $\lambda_i$ satisfy the symmetry requirements due to charge conjugation independently of the functions $A, B, X_i$ and $\overline{X}_i$. This is a particularly important point for modelling the quark-gluon vertex.

4 The soft gluon limit: an exact relation

A great deal of information can be learned from the above expressions by taking its soft gluon limit, i.e. by setting $p_3 = 0$. The interest on this particular kinematical configuration is that it has been investigated using lattice methods for full QCD with two flavors of quarks. In order to avoid the apparent singularity in the expressions for $\lambda_2$ and $\lambda_3$, one can set $p_1 = p$, $p_2 = -p + \delta$, $p_3 = -\delta$, expand all quantities in (15)–(18) up to first order in $\delta$ and, finally set $\delta = 0$. If one takes into account the all-order results of [5] which states that, in the soft gluon limit, $X_0(p^2) = 1$ and $X_1(p^2) = X_2(p^2)$, note the different notation concerning the definitions for $X_1$ and $X_2$, it follows that

$$
\lambda_1(p^2) = \frac{F(0)}{Z(p^2)} \left\{ 1 + 2 X_1(p^2) M(p^2) + 2 p^2 X_3(p^2) \right\},
$$

(19)

$$
\lambda_2(p^2) = \frac{F(0)}{2 Z(p^2)} \left\{ A'(p^2) - A(p^2) \right\} + M(p^2) \left\{ \partial_1 X_1(p^2) + \partial_2 X_2(p^2) \right\},
$$

(20)

$$
\lambda_3(p) = \frac{F(0)}{Z(p^2)} \left\{ B'(p^2) X_1(p^2) + X_1(p^2) \right\} + M(p^2) \left\{ \partial_1 X_0(p^2) - \partial_2 X_0(p^2) \right\} + p^2 \left\{ \partial_1 X_1(p^2) + \partial_2 X_2(p^2) \right\} - \partial_2 X_1(p^2) - \partial_1 X_2(p^2) \right\},
$$

(21)

with $\lambda_4(p^2) = 0$ and where $\lambda_i(p^2) = \lambda_i(p, -p, 0), A'(p^2) = \frac{d A(p^2)}{dp^2}, B'(p^2) = \frac{d B(p^2)}{dp^2}$. $X_i(p^2) = X_i(p^2, p^2, 0) = \overline{X}_i(p^2, p^2, 0) = \overline{X}_i(p^2)$ and $\partial_i X_j(p^2)$ is the partial derivative of $X_j(p_1^2, p_2^2, p_3^2)$ with respect to argument $i$ taken at $p_i^2 = p_2^2 = p^2$ and $p_3^2 = 0$. The expressions given in (19)–(21) imply the following exact relation

$$
\frac{Z(p^2)}{F(0)} \left\{ \lambda_1(p^2) + 4 p^2 \lambda_2(p^2) - 2 M(p^2) \lambda_3(p^2) \right\} = 1 - 2 M(p^2) M'(p^2) + 2 \left( p^2 - M^2(p^2) \right) \times \partial_1 X_0(p^2) - \partial_2 X_0(p^2) - \frac{Z'(p^2)}{Z(p^2)}
$$

(22)

between the non-vanishing longitudinal form factors. The r.h.s. of Eq. (22) requires only the knowledge of the quark propagator functions $Z(p^2)$ and $M(p^2)$ and of the quark-gluon kernel scalar form factor $X_0$. Further, for on-shell momenta, i.e. when $p^2 = M^2(p^2)$, the relation between the various form factors is independent of the quark-gluon.
kernel form factor $X_0$ and requires only the knowledge of the running quark mass. In principle, the functions $M(p^2)$, $Z(p^2)$ and its derivatives seem to smooth which suggest that the r.h.s. should not diverge either for infrared or ultraviolet momenta. Our present knowledge of $X_0$ also suggests that this quark-ghost kernel form factor and its derivatives are also finite. If this is the case, then the l.h.s. of Eq. (22) should also be always finite, preventing any divergence of the combination $\lambda_1(p^2) + 4 p^2 \lambda_2(p^2) - 2 M(p^2) \lambda_3(p^2)$. In other words, if any of the form factors diverges, its divergence has to be compensated by the remaining form factors.

5 The lattice soft gluon quark-gluon vertex

In [18] one can find full QCD lattice simulations for the quark propagator and $\lambda_1(p^2)$ for $N_f = 2$, in the Landau gauge, and for various lattice spacings. For completeness, on Fig. 2 top-frame we reproduce the bare lattice results for $\lambda_1(p^2)$. In the Landau gauge, at high momenta one expects $\lambda_1(p^2)$ to approach a constant value, up to logarithmic corrections. As the top of Fig. 2 shows this is not the case for all the lattice data. In particular, the simulations performed with $\beta = 5.29$ and $M_\pi = 242$ MeV together with that with $\beta = 5.20$ and $M_\pi = 280$ MeV are hardly constant at high momenta. This is certainly the result of a relative poor estimation of the lattice artefacts. A problem that has to be addressed by the lattice practitioners. In order to avoid possible contaminations of the lattice artefacts, in the analysis of the lattice data we will not take into account these two sets of results.

The lattice results for $\lambda_1(p^2)$ and $Z(p^2)$ provided in [18], combined with Eq. (19), can be used to estimate

$$Z(p^2) \lambda_1(p^2) = F(0) \left\{ 1 + 2 X_1(p^2) M(p^2) - 2 p^2 X_3(p^2) \right\}.$$  

(23)

Note the minus sign relative to Eq. (19) due to the Wick rotation to the Euclidean space. On the bottom-frame of Fig. 2 we report the lattice estimates for $Z(p^2) \lambda_1(p^2)$. The data for $Z(p^2)$ was interpolated to match the momenta available for $\lambda_1(p^2)$ and, at high momenta, we set $Z(p^2)$ to a constant matching its higher value. The lattice data reported on [18] show a slightly decreasing function $Z(p^2)$ for $p \gtrsim 2.5$ GeV. As discussed in the publication, this seems to be a lattice artefact and extrapolations to the “continuum” suggest that $Z(p^2)$ should, indeed, take a constant value.

The lattice data reported on the bottom-frame of Fig. 2 show a $Z(p^2) \lambda_1(p^2)$ that is constant, within the precision of the lattice simulation, for $p \gtrsim 2.5$ GeV. This complies with the predictions of perturbation theory which, at tree level, give $X_1(p^2) = X_3(p^2) = 0$. In principle the logarithmic corrections for $\lambda_1(p^2)$ should show up at high momenta. However, given the relative large errors on the lattice data for this form factor and given that the lattice data ends at $p \sim 10$ GeV, it is impossible to make any statement about the high momenta log behaviour for $\lambda_1(p^2)$.

The observed constant value is an estimation of the bare $F(0)$ value. To get a reference number for $F(0)$ we fitted the lattice data for $p \gtrsim 3$ GeV onwards to a constant. For the data referring to the $\beta = 5.40$ and $M_\pi = 242$ MeV simulation, the fit taking into account the correlations between the momenta gives a bare $F(0) = 1.2444(55)$ with a $\chi^2/d.o.f.$ of 0.05, while for the simulation using $\beta = 5.29$ and having a $M_\pi = 295$ MeV the correlated fit give a bare $F(0) = 1.4665(90)$ for $\chi^2/d.o.f.$ of 0.08. These figures are the constant lines appearing on the bottom-frame of Fig. 2. If one takes the smallest lattice momentum for each simulation as reference, it follows that relative to the constant fitted value $Z(p^2) \lambda_1(p^2)$ increases by a multiplicative factor of 1.86, for the $\beta = 5.40$ and $M_\pi = 242$ MeV simulation, and of 1.72, for the $\beta = 5.29$ and $M_\pi = 295$ MeV simulation. Then, from Eq. (23) one gets

$$\left[ 2 X_1(p^2) M(p^2) - 2 p^2 X_3(p^2) \right]_{p^2=0} = 0.86$$
for the $\beta = 5.40$ simulation and
\[
\left[ 2 X_1(p^2) M(p^2) - 2 p^2 X_3(p^2) \right]_{p^2 = 0} = 0.72
\]
for the $\beta = 5.29$ simulation. The finiteness of such a quantity means that either there are no infrared divergences on $X_1(p^2)$ and $p^2 X_3(p^2)$ or they cancel exactly.

In what concerns the form factor $\lambda_1(p^2)$ we observe that $Z(p^2) \lambda_1(p^2) - F(0)$ seems to be proportional to the Landau gauge lattice propagator. This can be seen on Fig. 3 where the lattice data is plotted together with the rescaled Landau gauge gluon propagator, from a simulation using a $64^4$ lattice and $\beta = 6.0$ [24, 25], and the two full QCD Landau gauge rescaled gluon propagators from simulations using $N_f = 2$ reported in [26]. The good agreement between the set of data closer to the physical limit is impressive. On Sect. 6 we are able to link $\lambda_1(p^2)$ and the gluon propagator relying on a Bethe–Salpeter equation for the vertex.

The understanding of the remaining soft gluon form factors $\lambda_2(p^2)$ and $\lambda_3(p^2)$, see Eqs. (20) and (21), is more cumbersome as their dependence on the quark propagator and quark-ghost kernel form factors is more elaborated.

For $\lambda_2(p^2)$, the estimates performed in [5] do not provide a very clear picture. Indeed, the authors discuss two different calculations. In their simplest analysis for $\lambda_2(p^2)$, this form factor is small over the full range of momenta. However, by improving the angular dependence, that is taken into account partially, then $\lambda_2(p^2)$ seems to have an infrared divergence. This later result does not seem to comply with our analysis. The computation of $\lambda_2(p^2)$ within the Curci–Ferrari model [27] points towards a small contribution from this form factor that reaches a maximum of $\sim 0.2$ GeV$^{-2}$ at zero momenta or close by. The results of one-loop dressed perturbation theory [12] also suggest a small $\lambda_2(p^2)$ at small momenta. In what concerns lattice estimations of $\lambda_2(p^2)$, one can find in the literature only results for quenched simulations [28]. The lattice form factor does not agree with the estimates just mentioned for $\lambda_2(p^2)$ and suggests a functional behaviour that is not necessarily closer to the other estimations. There is an ongoing discussion about the estimation of the lattice artefacts and a possible contamination of the lattice calculation due to the transverse form factors; see e.g. Ref. [27].

For the form factor $\lambda_3(p^2)$ the estimates of [5, 12, 27] and the results of quenched lattice simulations [28] point towards a sizeable form factor. Given our lack of knowledge of the various terms in (21) it is difficult to provide any information on the form factor directly from this equation. However, after dividing Eq. (22) by $Z(p^2)$, its r.h.s. contains only information about the quark propagator and the derivatives of $X_0$. This relation is a non-trivial constraint on the non-vanishing $\lambda_i(p^2)$. Unfortunately, the r.h.s. of the equation requires the knowledge of the derivatives of the mass function and of the quark wave function that are difficult to evaluate directly from the lattice data. One can estimate the r.h.s. of the equation using the fits provided in [3] as shown on Fig. 4 if one ignores the contribution of the $X_0$ derivatives. In the UV region it is essentially flat for momenta $p \gtrsim 1$ GeV and it decreases significantly only for $p \lesssim 300$ MeV. Given that $\lambda_2(p^2)$ is always small and is multiplied by $p^2$, that $\lambda_1(0) \approx 1$, as shown on Fig. 2, this can be seen as an indication that $\lambda_3(p^2)$ takes large values only for $p \lesssim 300$ MeV, in agreement with the results observed in the cited articles.

### 6 Discussion

The observations reported on the previous section for the soft-gluon limit can be understood looking at the one-loop Bethe–Salpeter equation (BSE), in the fully dressed ladder approxi-
Fig. 5 One-loop dressed Bethe–Salpeter equation for the quark-gluon vertex. The big blobs represent the dressing, and small blobs are bare vertices.

In the limit \( p_1 - q \rightarrow 0 \), the BSE is renormalized in the MOM-scheme at \( \Lambda = 3 \text{ GeV} \). The previous discussion when building Fig. 3 gives a \( a_L = F(0) \approx 1.24 \) for the \( \beta = 5.40 \) (\( M_\pi = 426 \text{ MeV} \)) data and a \( a_L = F(0) \approx 1.47 \) for \( \beta = 5.29 \) (\( M_\pi = 295 \text{ MeV} \)) data. The quenched gluon propagator in Fig. 3 was renormalized in the MOM-scheme at \( \mu = 3 \text{ GeV} \) and it was rescaled by a factor of \( \sim 0.12 \text{ GeV}^2 \) to produce the figure. The full QCD gluon propagator for the \( \beta = 4.20 \) simulation was also renormalized in the MOM-scheme at \( \mu = 4.3 \text{ GeV} \) and rescaled by a factor of \( \sim 0.19 \text{ GeV}^2 \) to produce the figure. From its definition we have that \( b_L = c F(0) \), where \( c \) is a dimensionless factor that corrects for the momentum scale and, therefore, the quoted figures should be read as orders of magnitude. Note also that the above picture applies to the data closer to the physical limit. Indeed the form factor and the constant \( c \) are not independent of the renormalization scale and, therefore, the quoted figures should be read as orders of magnitude. Note also that the above picture applies to the data closer to the physical limit. Indeed the form factor depends on the quark (pion) mass in such a way that for larger values of the mass, the decrease of \( Z(p^2) \lambda_1(p^2) \) or \( \lambda_1(p^2) \) is slower and, therefore, the above argument does not apply for sufficiently heavier quark masses.

Despite the relative large statistical and lattice artefacts observed on the lattice data, our empirical analysis based on Eqs. (23) and (25) supports the factorization of \( \lambda_1(p^2) Z(p^2) \) in such a way that

\[
F(0) \left( 2X_1(p^2)M(p^2) - 2p^2 X_3(p^2) \right) \\
\approx a'_L + b_L A_{QCD}^2 \Delta(p^2),
\]

with \( a'_L = a_L - F(0) \approx 0 \). It is the gluon propagator that dominates the relevant momentum behaviour of the product \( \lambda_1(p^2) Z(p^2) \) at infrared scales. Furthermore, this result evidences the ladder dominance, as already suggested by
the rainbow-ladder approximation of the Dyson–Schwinger equation for the quark propagator and used in many phenomenological applications of continuum methods to treat strong QCD to study mesons and baryons properties [4]. If one assumes that the product $X_1(p^2)M(p^2)$ carries the dominant momentum behavior, then $X_1(p^2)M(p^2) \propto \Delta(p^2)$. Such a feature is important in building a quark-gluon vertex model having dependence not only on the gluon momentum but also on the quark momentum. Eventually such factorization can be extended to the other components of the quark gluon vertex in the soft gluon limit.

7 Summary

The longitudinal component of the quark-gluon vertex in the soft gluon limit is studied combining information from Lattice QCD simulations and a Slavnov–Taylor identity. In the soft gluon limit, the Slavnov–Taylor identity allows to write the longitudinal form factors in terms of the quark–ghost kernel and the quark propagator functions. Further, the STI implies, in the soft gluon limit, an exact relation that combines linearly $\lambda_1$, $\lambda_2$ and $\lambda_3$ with differences between derivatives of $X_0$, the quark self energy and the quark wave function.

From full QCD lattice simulation data for $\lambda_1(p^2)$ in the Landau gauge we are able to estimate some of the quark-ghost kernel form factors. The data also allows to explore the remaining non-vanishing quark-gluon vertex functions $\lambda_2(p^2)$ and $\lambda_3(p^2)$. We found that the provided estimations are within typical values found in the literature.

In particular for $\lambda_1(p^2)$ the analysis of the recent full QCD Landau gauge lattice simulations reveals an empirical relation linking $\lambda_1(p^2)$ with the gluon propagator $\Delta(p^2)$. This relation seems to hold for the momenta accessed on the lattice data. The relation between $\lambda_1(p^2)$ and $\Delta(p^2)$ is found in the solution of a fully dressed one-loop Bethe–Salpeter equation for the quark-gluon vertex. The analysis of the BSE suggests that the factorisation holds for other components of the vertex in the soft gluon limit and, eventually, also for its transverse components. Such challenging investigation is left for future work. The connection between the $\lambda_i$ and the gluon propagator can contribute to model the quark-gluon vertex including not only the dependence on the gluon momentum but also the quark momentum.
