Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Case Report

Bilateral posterior cerebral artery territory infarction in a SARS-Cov-2 infected patient: discussion about an unusual case

Claire Bonardel, MD,*1 Mathieu Bonnerot, MD,+2 Marie Ludwig, MD,*3 Wilfried Vadot, MD,†4 Gaspard Beaune, MD,‡5 Bruno Chanzy, MD,‡6 Lucie Cornut, MD,*7 Hélène Baysson,§8 Magali Farines,§9 Isabelle Combes,§10 Gabriel Macheda, MD,¶11 and Fabrice Bing, MD, PhD*

In time of SARS-Cov2 pandemic, neurologists need to be vigilant for cerebrovascular complications of Covid-19. We present a case of bilateral occipito-temporal infarction revealed by a sudden cortical blindness with haemorrhagic transformation after intravenous thrombolysis in a diabetic patient infected by Covid-19. Differential diagnoses are discussed in front of this unusual presentation and evolution.

Case presentation

A 51-year-old-man presented with one-week history of cough, dysgeusia and diarrhea. The patient complained of moderate headache without fever. The patient had a history of diabetes mellitus, hypertension and obesity. Blood investigation showed a lymphocytopenia (1.08 giga/L), an increased fibrinogen (5.1 g/L), ferritin (1190 µg/L), creatin-kinase (749 UI/L), C-reactive protein (71 g/L), ASAT (54 UI/L) and glycated hemoglobin (9.1%) concentrations. Prothrombin Ratio was low (66%). Antiphospholipid, platelets and partial thromboplastin time were normal. The RT-PCR for SARS-Cov-2 using a nasopharyngeal swab was positive. A chest scan showed bilateral ground glass opacities concerning more than 50% of the parenchymal lung (Fig. 1). Six days after arrival and 30 min after the fourth injection of remdesivir (loading dose: 200 mg IV, 100 mg IV per day thereafter), he presented an abrupt cortical blindness and disorientation (NIHSS score: 4). An atrial fibrillation (AF) was recorded. A first brain MRI performed one hour after clinical onset showed bilateral and asymmetric acute occipito-temporal infarction without visibility of the P3 segments of the posterior cerebral arteries (PCA) (Fig. 2A to C). Fluid-attenuated inversion recovery (FLAIR), T2*, MR venography and MR angiography of the supra-aortic trunks were normal. No pathological enhancement in leptomeningeal spaces was observed. Alteplase was injected 128 min after symptom onset. The following morning, blindness was unchanged and anterograde memory disorders with anosognosia were noticed. The 24 h control multimodality MRI showed a haemorrhagic transformation of the previous lesions (Fig. 2E-F). Dynamic susceptibility-weighted contrast-enhanced magnetic resonance perfusion imaging (DSC-MRI perfusion) showed an increase of cerebral blood flow. volume (CBV) and flow (CBF) in the right thalamus and an increase of the mean transit time (MTT) and CBV in the right hemisphere (Fig. 1H). Distal segments of the PCA were permeable (Fig. 2D). Nine hours later, the patient died due to a rapid respiratory breakdown, without neurological worsening.

**Discussion**

This bilateral cerebral posterior stroke may be secondary to an embolic event (AF). Stroke could also be explained by the state of hypercoagulability induced by SARS-Cov-2 infection. Severe patients are more likely to have neurologic symptoms and bilateral frontotemporal hypoperfusion has been reported. In our case, MTT and CBV were increased in the right hemisphere which may reflect reduced cerebral perfusion pressure. The increase value of the CBF in the right thalamus may correspond to a post-recanalization hyperperfusion.

Other stroke mechanisms can be suggested. Infection may have induced cerebral vasculitis, explaining the stroke and the perfusion’s anomalies. Severe reversible cerebral vasocostriction syndrome (RCVS) cases with cerebral infarction and intracranial haemorrhage have been reported but the absence of thunderclap headache is unusual in RCVS. The absence of rapid increase in blood pressure and the presence of an initial cytotoxic oedema instead of vasogenic is less in favour of Posterior Reversible Encephalopathy Syndrome (PRES). An adverse effect of remdesivir is also to be discussed, but no neurological adverse effect potentially related to remdesivir have been reported. Finally, the absence of thalamus involvement makes the diagnosis of acute necrotizing encephalitis unlikely.

In conclusion, the origin of the stroke is probably multifactorial: the cytokine storm syndrome and hypercoagulability may have induced blood flow dysregulation, associated with an embolic event that may finally induce arterial thrombosis. A cerebral artery vasculitis or a RCVS are not excluded. This unusual case confirms the increased risk of thrombotic events in SARS-Cov2 infected patients.
