presented by B.A. Shwartz

The status of the experiment on the precise $\tau$ lepton mass measurement running at the VEPP-4M collider with the KEDR detector is reported. The mass value is evaluated from the $\tau^+\tau^-$ cross section behaviour around the production threshold. The preliminary result based on 6.7 pb$^{-1}$ of data is $m_\tau = 1776.80_{-0.23}^{+0.29} \pm 0.15$ MeV. Using 0.8 pb$^{-1}$ of data collected at the $\psi'$ peak the preliminary result is also obtained: $\Gamma_{ee}B_{\tau\tau}(\psi') = 7.2 \pm 2.1$ eV.

1. Introduction

The $\tau$ lepton mass, $m_\tau$, is one of the fundamental characteristics of the Standard Model. Together with the lifetime and the decay probability to $e\bar{\nu}_e\nu_\tau$ this value can be used to test the lepton universality principle which is one of the postulates of the modern Electroweak theory. The world average value $m_\tau = 1776.99_{-0.26}^{+0.29} [1]$ is dominated by the result of the BES collaboration [2] which statistical analysis and uncertainty estimations were recently discussed in Refs. [3] and [4]. Thus, the additional measurements are desirable to improve the mass accuracy and ensure future progress in the lepton universality tests.

The direct method of the $\tau$ mass determination is a study of the threshold behaviour of the $\tau^+\tau^-$ production cross section in $e^+e^-$ collisions as it was done in the experiments [5] and then [2]. The key question of such experiments is the precision in the beam energy determination. The important feature of the present work is an application of two independent methods of the beam energy measurement, while the previous experiments relied on the extrapolation based on the $J/\psi$ and $\psi'$ mesons as reference points. It should be noted as well that the beam energy in our experiment is monitored with the accuracy better than $5 \cdot 10^{-5}$ and the absolute energy calibration is done with the precision of $1 \cdot 10^{-5}$.

2. VEPP-4M collider and KEDR detector

The VEPP-4M/VEPP-3 accelerator complex is presented schematically in Figure 1. The VEPP-4M collider [6] has the circumference of...
366 m and operates in 2×2 bunch mode. The beam energy can vary in the range of 1÷6 GeV; the peak luminosity at the \( \tau \)-production threshold \( E_{\text{beam}} \approx 1.78 \text{ GeV} \) is about \( 2 \cdot 10^{30} \text{ cm}^{-2}\text{s}^{-1} \).

The beams, optionally polarized, are injected from the VEPP-3 booster at the energy up to 1.9 GeV. This allows to apply the resonant depolarization method (RDM) \([7]\) for the precise energy calibration. The Touschek (intra-beam scattering) polarimeter of VEPP-4M (Figure 1a) requires special runs for the calibration. During data taking, the beam energy can be monitored using the Compton backscattering (CBS) of the infra-red laser light (Figure 1b) by the method developed at the synchrotron light source BESSY-I \([8]\). The statistical accuracy of the single measurement is about 100 keV, the systematic uncertainty of the method verified by the resonant depolarization is close to 60 keV.

The KEDR detector \([9]\) consists of the vertex detector, the drift chamber, the time-of-flight system of scintillation counters, the particle identification system based on the aerogel Cherenkov counters, the calorimeter with the longitudinal segmentation (the liquid krypton in the barrel part and the CsI crystals in the end caps) and the muon tube system inside the magnet yoke. Currently KEDR operates at the magnetic field of 6 kGs.

The longitudinal segmentation of the calorimeter provides good \( e/\pi \) identification used to select \( \tau^+\tau^- \) events.

### 3. Experiment scenario

A cross section of the process \( e^+e^- \rightarrow \tau^+\tau^- \) measured at certain center-of-mass energy \( W \) is expressed as

\[
\sigma(W) = \frac{1}{\sqrt{2\pi}\sigma_W} \int dW' \exp \left\{ -\frac{(W-W')^2}{2\sigma_W^2} \right\}
\]

\[
\int dx \ F(x,W') \sigma_{fs}(W'\sqrt{1-x}),
\]

where the first integral stands to take into account c.m.s. energy spread, \( \sigma_W \), the second one accounts the energy loss due to the initial state radiation \([10] \), while

\[
\sigma_{fs}(W) = \frac{4\pi\alpha^2}{3W^2} \beta(3-\beta^2) \ F_r(\beta) F_s(\beta) \quad \text{if} \quad |1-\Pi(W)|^2
\]

includes the Coulomb interaction correction \( F_r(\beta) = (\pi\alpha/\beta)/(1-\exp(-\pi\alpha/\beta)) \), the final state radiative correction \( F_s(\beta) \) \([11]\) and the vacuum polarization effect \( |1-\Pi(W)|^2 \). The quantity \( \beta = (1-(2m_\tau/W)^2)^{1/2} \) is the \( \tau \) lepton velocity.

Due to Coulomb interaction of the produced \( \tau^+ \) and \( \tau^- \) the cross section \([2]\) energy dependence has a step at \( W = 2m_\tau \) (Figure 2).
Figure 3. The VEPP-4M operation scenario in 2005-2006 (in 2004-2005 only high-rate Compton backscattering measurements were used, incompatible with the data taking).

The narrow region of a few MeV around the threshold is most sensitive to the mass value. For this reason the following scan scenario was chosen: 70% of the integrated luminosity \( \mathcal{L} \) are taken at three points \( E_{\text{beam}} = m_\pi - 0.5, m_\pi, m_\pi + 0.5 \) MeV with the world average value of \( m_\pi \). 15% of the data are collected well below the threshold to fix the background level \( \sigma_B \) and remaining 15% well above the threshold to determine the effective detection efficiency \( \varepsilon \). The interval of \( \pm 0.5 \) MeV covers possible uncertainty of the mass; a few additional points above the threshold were foreseen to increase the robustness of the three-parameter data fit.

4. Beam energy determination

A conventional way of the beam energy determination is a calculation based on the measured magnet currents. It provides the relative accuracy that seems to be not better than \( 3 \cdot 10^{-4} \). The uncontrollable energy variations are of the same order of magnitude. Thus the precise beam energy calibration is required for the \( \tau \) mass determination and, at least, the reliable energy stability tests are necessary for an accurate uncertainty estimate.

In the previous KEDR experiments on the high precision \( J/\psi \) and \( \psi' \) meson mass measurements \[12\] various sources of the systematic uncertainties in the beam energy determination were thoroughly studied to achieve a 10 keV accuracy.

In this experiment the basic energy calibrations were performed by the resonant depolarization with the smoothing interpolation of the RDM results between the calibrations as described in Ref. \[12\] (the guiding field measurements and the ring and the tunnel temperature measurements are employed for the interpolation).

The improvements of the Touschek polarimeter (Figure 1a) done since 2003 have allowed to operate at \( E_{\text{beam}} \approx 1772 \) MeV, where the polarization lifetime is \( \lesssim 1000 \) sec because of the closeness of the integer spin resonance \( \nu = 4 \) (1762.59 MeV). However, the absence of polarization in VEPP-3 at the energy region of 1700÷1830 MeV forced to employ the complicated machine operation scenario shown in Figure 3. After staying in the threshold region the magnetization cycle must be performed in VEPP-4M to inject the polarized beam above the region quoted. This and also some forced changes in the accelerator cooling system reduced the accuracy of the energy interpolation between the calibrations from 8 keV obtained in \[12\] to 30 keV.

The resonant depolarizations were performed normally once per day with the accuracy better than 20 keV. The results of the typical resonant depolarization run is shown in Figure 4. Between the depolarizations the energy was directly measured using the CBS monitor (Sec. 2) and Figure 5 with the statistical accuracy of about
100 keV. The multiparameter fit of the Compton spectrum edge is shown in Figure 5. It accounts for the nonuniform background and the detection efficiency variations.

At the $J/\psi$ peak the 11% deviation from the expected value of $\sigma_W(J/\psi) = 0.72 \pm 0.01 \pm 0.02$ MeV.

At the $J/\psi$ peak the 11% deviation from the expected value of $\sigma_W(J/\psi) = 0.72 \pm 0.01 \pm 0.02$ MeV. A similar deviation took place during the $J/\psi$-mass measurements [12] with the different spread-related settings.

Assuming the linear growth of the deviation with $W - M_{\psi}$ we obtained

$$\sigma_W(2m_{\tau}) = 1.07 \pm 0.02 \pm 0.04$$ MeV.

No essential dependence of the energy spread on the beam current was observed at the $\psi'$ region neither in the resonance scans nor by means of the beam diagnostic [13].

6. Selection of $\tau$ events

To diminish systematic uncertainties the event selection criteria were chosen as loose as possible when a background was kept to be negligible. The two-prong events due to

$$e^+e^- \rightarrow (\tau \rightarrow c\nu_\tau \bar{\nu}_e, \mu \nu_\tau \bar{\nu}_\mu, \pi \nu_\tau, K \nu_\tau, \rho \nu_\tau)$$

$$+ \text{ c.c.}$$

were selected. At least one track must be identified as an electron using the signal in the calorimeter and the momentum measurements. The $\mu/\pi/K$ identification was not applied; it does not reduce the systematic uncertainty of the mass. No photons with $E_\gamma > 30$ MeV were allowed. The other cuts were $E < 2200$ MeV,
\( p_T > 200 \text{ MeV, } p_T/(W - E) > 0.06, \) where \( p_T \) is the total transverse momentum, \( E \) is total energy of the detected particles and \( W = 2E_{\text{beam}} \).

\[
\begin{align*}
\text{Figure 7.} & \quad \text{The distributions in the } p_T \text{ over the missing energy } (W - E) \text{ (left) and in the invariant mass of the detected system (right); the real data (small statistics) and the simulation (high statistics).}
\end{align*}
\]

With such cuts the residual background (mainly two-photon) is expected to be uniform in the energy region of the experiment. According to the Monte Carlo calculations, the detection efficiency at the \( \tau \) threshold is about 2.5\% with the relative reduction by 10\% at \( W = 3777 \text{ MeV} \).

The distributions in some parameters of interest for the real data and the simulation are presented in Figure 7.

7. Preliminary results

The preliminary results of the \( \tau^+\tau^- \) threshold scan are collected in Table 1 and presented in Figure 8. The energy \( \langle E \rangle \) assigned to the point is the average of all measured values. The corresponding standard deviation \( \delta_E \) is related to the machine energy instability and is much less than the beam energy spread \( \sigma_E \approx \sigma_W / \sqrt{2} \).

To determine the value of \( \tau \) lepton mass the log-likelihood fit of the observed number of events in the nine points were done. The expected number of events in the point was parameterized as

\[
n_i = (\varepsilon \tau; \sigma(2\langle E \rangle_i, m_\tau) + \sigma_B) L_i, \quad (3)
\]

where \( \varepsilon, m_\tau \) and \( \sigma_B \) are the free parameters of the fit defined in Sec. 3 and \( r_i \) is the relative efficiency variation obtained with the Monte Carlo simulation. The cross section \( \sigma(W, m_\tau) \) was calculated according to Eq. 1 with the additional term describing \( \psi' \) production and decay; it contains \( \Gamma_{\text{ex}} B_{\tau \tau}(\psi') \) as an additional free parameter.

The fit yielded in

\[
\begin{align*}
m_\tau &= 1776.80_{-0.23}^{+0.25} \text{ MeV}, \\
\varepsilon &= 2.29 \pm 0.25 \%, \\
\sigma_B &= 0^{+0.57}_0 \text{ pb}, \\
\Gamma_{\text{ex}} B_{\tau \tau}(\psi') &= 7.2 \pm 2.1 \text{ eV},
\end{align*}
\]

\[
\begin{align*}
\sigma_{\text{obs}}^{\tau\tau} \quad (\text{MeV}) & \quad (\text{MeV}) & \quad (\text{nb}^{-1}) & \quad (\text{pb}) \\
1 & 1771.945 & 0.160 & 668 & 0 & 0.0^{+2.8}_0 \\
2 & 1776.408 & 0.086 & 1382 & 1 & 0.7^{+1.7}_-{0.6} \\
3 & 1776.896 & 0.061 & 1288 & 4 & 3.1^{+2.5}_-{1.5} \\
4 & 1782.103 & 0.060 & 283 & 4 & 14.1^{+11.3}_-{6.8} \\
5 & 1792.457 & 0.102 & 233 & 3 & 12.9^{+12.5}_{-7.1} \\
6 & 1837.994 & 0.092 & 305 & 14 & 45.8^{+16.0}_{-12.2} \\
7 & 1843.040 & 0.065 & 807 & 79 & 97.9^{+11.0}_{-11.0} \\
8 & 1888.521 & 0.228 & 967 & 49 & 50.7^{+7.2}_{-7.2} \\
9 & 1888.521 & 0.228 & 967 & 49 & 50.7^{+7.2}_{-7.2} \\
total (excluding \psi') & & & 6731 & 81 & \\
\end{align*}
\]

\[
\begin{align*}

\end{align*}
\]
6

Table 2
The preliminary estimates of the systematic uncertainties in the $\tau$ lepton mass (keV).

| Source of Uncertainty                          | Estimate (keV) |
|------------------------------------------------|----------------|
| Beam energy determination                      | 40             |
| Detection efficiency variations                 | 100            |
| Energy spread determination accuracy            | 25             |
| Energy dependence of the background             | 20             |
| Luminosity measurement instability              | 90             |
| Beam energy spread variation                    | 15             |
| Cross section calculation (r.c., interference)  | 30             |
| **Sum in quadrature**                           | **150**        |

The background is consistent with zero.

The preliminary estimates of the systematic uncertainties in $m_\tau$ are summarized in Table 2. The detector-related uncertainties, currently dominating, can be substantially reduced with further data analysis.

8. Conclusion

The $\tau$–threshold experiment with the precise beam energy monitoring is in progress at the VEPP-4M collider with the KEDR detector. The preliminary result on the $\tau$ lepton mass

$m_\tau = 1776.80^{+0.25}_{-0.23} \pm 0.15 \text{ MeV}$

is in good agreement with the world average

$m_\tau = 1776.99^{+0.29}_{-0.26} \text{ MeV}$ [1]

and has approximately the same accuracy.

Using 0.8 pb$^{-1}$ at the $\psi'$ peak the following preliminary result was obtained for the $\psi' \to \tau\tau$ decay probability:

$\Gamma_{ee} \cdot B_{\tau\tau}(\psi') = 7.2 \pm 2.1 \text{ eV}$,

The product of the world average values [1] is

$\langle \Gamma_{ee} \rangle \cdot \langle B_{\tau\tau} \rangle (\psi') = 6.9 \pm 1.7 \text{ eV}$.

Data taking for this experiment is continued with a goal to achieve a 0.15 MeV accuracy in the $\tau$ mass. The accuracy of $\psi' \to \tau\tau$ decay probability will be also well improved.
