Received 25 October 2004/Returned for modification 24 November 2004/Accepted 7 January 2005

Heartwater (cowdriosis) is a major tick-borne disease of ruminants caused by the rickettsia *Ehrlichia ruminantium* and is transmitted by ticks of the genus *Amblyomma*. *Amblyomma variegatum* is the major vector in West Africa (22), is distributed throughout most of sub-Saharan Africa, and occurs on some islands in the Caribbean (23). Heartwater represents a major constraint to improvement of the livestock industry in sub-Saharan Africa. In The Gambia and neighboring Senegal, serological evidence of a high prevalence of *E. ruminantium* infection has been reported in cattle (8, 10, 17), which indicates a potential risk of heartwater disease for susceptible livestock. In contrast to what occurs in indigenous cattle, which appear more resistant to heartwater (6, 16), the disease has been known in small ruminants in The Gambia as “fayo,” referring to cases of sudden death, characteristic of acute forms of the disease (23). Mortality occurs in indigenous local dwarf sheep and goats and is estimated at 10% in areas of the country where the disease is endemic (R. Mattioli and J. Jaitner, unpublished data). In addition, frequent occurrences of sudden death due to heartwater have been observed in indigenous sheep and goats following translocation from the east to the west of the country (B. Faburay, unpublished observation). These observations suggest the existence of a gradient of heartwater disease risk for susceptible livestock species and the possibility that a significant proportion of the small-ruminant population in the east of the country has not been exposed to *E. ruminantium* infection. We carried out a countrywide serological survey to determine the distribution of *E. ruminantium* infection in small ruminants and to assess the heartwater risk for susceptible livestock.

**MATERIALS AND METHODS**

**Survey.** Serum samples were collected from Djallonké sheep and West African dwarf goats of both sexes in a cross-sectional study at 28 sites in all five divisions of The Gambia: the Western, Lower River, North Bank, Central River, and Upper River divisions (Fig. 1). The sites were located in three main agroecological zones: Sudanian, Sudano-Sahelian, and Sahelian. The sites were chosen in consultation with livestock assistants based on owner cooperation and accessibility to the animals. Adult animals between 1 and 3 years of age were sampled in April 2004. All animals were maintained under a traditional husbandry system without acaricide treatment. Blood samples were kept on ice, and serum was separated after 2 to 4 h by centrifugation and stored at −20°C until use. A total of 1,318 indigenous small ruminants comprising 639 sheep and 679 goats were sampled. The sites were selected in a transect layout to make the results representative of the country. The numbers sampled at different sites for each species are shown in Table 1. The largest number of sampling sites was in the Western Division, as this area is experiencing an expansion of a livestock-upgrading program carried out by the Gambian government in collaboration with the International Trypanotolerance Centre (ITC), involving cattle breeds (Holstein and Jersey) highly susceptible to heartwater disease.

**MAP1-B ELISA.** The indirect MAP1-B enzyme-linked immunosorbent assay (ELISA), based on a recombinant truncated form of major antigenic protein 1 of *E. ruminantium*, was carried out as described previously (18, 21). Although the
assay does not detect antibodies to ehrlichial agents infecting domestic ruminants, such as *Ehrlichia bovis* and *Ehrlichia ovina*, antibodies are detected against *Ehrlichia canis* (which infects dogs) and *Ehrlichia chaffeensis* (a human pathogen) (21). The MAP1-B ELISA has been shown to perform satisfactorily for small ruminants (5, 15), with specificities of 98.9% and 99.4% for caprine and ovine sera, respectively (19, 21). Each serum sample was tested in duplicate. For sheep, each test included duplicate negative-control sera obtained from a heartwater-naïve sheep of the Tesselaar breed. Duplicate positive-control sera were ob-

|                           | Missira       | 15   | 100 (13) | 40 (5) | 83.3 (18) |
|                           | Taborongkoto  | 14   | 85 (20) | 33.3 (3)\(^c\) | 78.3 (23) |
| **Central River Division** | Jimballa Kerr Chendu | 22 | 41 (61) | 7.7 (32) | 25.7 (113) |
|                           | Mamutiana     | 18   | 6.9 (72) | 0 (20) | 54.3 (92) |
|                           | Sare Sofie    | 21   | 31.3 (16) | 0 (8) | 20.8 (24) |
|                           | Sinchan Faranba | 20   | 29.6 (27) | 1.5 (69) | 9.4 (96) |
|                           | Yorro Beri Kunda | 19  | 100 (12) | 17.7 (17) | 51.7 (29) |
| **Upper River Division**  | Kulkullay     | 23   | 22.2 (54) | 4.2 (48) | 13.7 (102) |
|                           | Missira Sandou | 24   | 47.6 (42) | 0 (20) | 32.3 (62) |
|                           | Sure Demba Torro | 25  | 26.7 (15) | 0 (18) | 12.1 (33) |
| **North Bank Division**   | Kolli Kunda   | 26   | 68.8 (16) | 48.7 (37) | 54.7 (53) |
|                           | Mbappa Ba     | 27   | 50 (16) | 50 (22) | 50 (38) |
|                           | Mbappa Mariga\(^a\) | 28  | 24.3 (37) | 73.2 (41) | 50 (80) |

\(^a\) Village with a high introgression of Sahelian sheep genes into the local population.

\(^b\) No sheep were sampled in the Talokoto and Toubakuta villages.

\(^c\) Prevalence was based on a small sample size, as there were very few animals presented for sampling.
TABLE 2. Proportions of total small-ruminant populations in the five divisions of The Gambia and overall heartwater seroprevalence rates

| Division                  | No. of sites | % of total livestock* | % of seropositive animals (total no. sampled) | Probabilitya |
|---------------------------|--------------|-----------------------|-----------------------------------------------|--------------|
|                           |              | Sheep | Goats | Total | Sheep | Goats |                      |
| **Western Division**      |              |       |       |       |       |       |                      |
| Lower River Division      | 5            | 7.9   | 11.8  | 10.2  | 63.1 | 21.9 | <0.001               |
| North Bank Division       | 3            | 43.5  | 59.0  | 52.3  | 40.6 | 59.0 | 0.019                |
| Central River Division    | 3            | 12.7  | 23.5  | 19.0  | 45.3 | 90.0 | <0.001               |
| Upper River Division      | 3            | 25.0  | 18.0  | 20.9  | 32.4 | 21.9 | <0.001               |

a Deduced from reference 1.

Probability determined by comparing differences between the proportions of seropositive sheep and seropositive goats in a division (a P value of 0.05 or less is significant).

DISCUSSION

*Ehrlichia ruminantium* seroprevalence in small ruminants was found to be highest in the western part of The Gambia, with the Western Division showing the highest prevalence of nearly 60% and the Lower River and North Bank divisions showing seroprevalences of more than 50%. Although the two easterly divisions, Central River and Upper River, account for the highest proportions of the small-ruminant population in The Gambia of 38.4% and 20.9%, respectively (Table 2), the overall seroprevalence of *E. ruminantium* in small-ruminant populations in these regions was significantly lower than in the westerly divisions (Western, North Bank, and Lower River) (Fig. 2). At most sites in the Central River and Upper River divisions, the serological prevalence was generally lower than 50%, resulting in a substantial population of sheep and goats being susceptible to heartwater.

In a recent study (E. Hoeven et al., unpublished data) a relatively high introgression of Sahelian genes was found in indigenous goats in the Central River Division as opposed to those in the Western Division. Interestingly, the easterly region accounts for over 60% of the small-ruminant population in The Gambia (Table 2), of which Sahelian sheep and goats and their crosses with local dwarf sheep and dwarf goats constitute a significant proportion. Generally, Sahelian sheep and goats found in the easterly part of The Gambia originate from *Amblyomma*/heartwater-free areas in northern Senegal and are...
therefore susceptible to heartwater disease. However, due to their larger size, farmers in this region show preference for them and use them for crossbreeding with local sheep and goats. The above factors therefore suggest the existence of a lower risk of *E. ruminantium* infection in most of the eastern part of the country. Thus, small ruminants, including those of susceptible Sahelian genotypes, may have a greater chance of survival in these areas. This, among other factors, possibly allowed the proliferation of large populations consisting of local dwarf sheep and goats and crossbred (Djallonké sheep/ West African dwarf goat × Sahelian sheep/goats) as well as Sahelian small ruminants.

Heartwater, described as a case of sudden death in small ruminants, is perceived as a major problem by farmers in The Gambia. Our unpublished observations confirmed that small ruminants have suffered mortality due to confirmed cowdriosis after translocation from the Central River Division to the coast in the Western Division. Although possible antigenic variation between stocks of *E. ruminantium* (11, 12) in the different regions of The Gambia may be a possible cause of the mortalities (since there was no record on the immune status of the translocated animals), it is postulated that small ruminants that died from heartwater, after translocation from the east to the west of the country, constituted a naïve group that had no previous exposure to *E. ruminantium* infection. Furthermore, in a 3-year period (1997 to 1999) of monitoring by postmortem analysis the major causes of mortality in local dwarf sheep and goats at an ITC field station in Keneba in the Lower River Division, heartwater, confirmed in brain-crush smears, accounted for 36% of deaths in sheep and 25% in goats (R. Mattioli and J. Jaitner, unpublished data). Analysis of similar data collected from October 1996 to January 1999 from local dwarf sheep and goats at the ITC Kerr Seringe station in the Western Division showed that deaths due to heartwater were 17.9% in sheep and 12.5% in goats. The higher seroprevalence in sheep observed in this study, combined with lower incidences of clinical disease in goats in The Gambia as indicated above, appears to agree with the observations made elsewhere in West Africa by Koney et al. (14) that local dwarf goats in Ghana are more resistant to heartwater than dwarf sheep. The higher seroprevalence in sheep could also be an indication that local dwarf sheep are more tolerant of *E. ruminantium* infection than dwarf goats or merely that sheep are more frequently infested with *A. variegatum* ticks than goats. A longitudinal study in Ghana of *E. ruminantium* seropositivity using a competitive ELISA (20) with sensitivity comparable to that of the MAP1-B ELISA (4) revealed high antibody levels detectable for longer periods in sheep than in goats (3). Therefore, it is also possible that the higher seroprevalence in sheep could be due to longer persistence of antibodies. Interestingly, although both sheep and goats are vulnerable to the disease, peracute cases of heartwater are reported to be more common in the latter (23). This requires further investigation.

Surveys of *E. ruminantium* seroprevalence in small ruminants have been carried out in other parts of Africa. In Ghana, Koney et al. (14) reported a seroprevalence of 51% for sheep and 28% for goats, figures that are comparable with those of 51.6% for sheep and 30.3% for goats in the present study. In north Cameroon, using a modified polyclonal ELISA, a mean *E. ruminantium* prevalence of 58 to 66% was reported for sheep and 65 to 66% for goats (1a). In a comparable study in southern Africa, using the MAP1-B ELISA, a lower *E. ruminantium* seroprevalence was detected in indigenous goats in the northern part of Mozambique (8.1%) than in the southern part (65.6%), resulting in mortalities due to heartwater after translocation of animals from the north to the south (2). These findings suggest that a substantial proportion of small-ruminant populations in parts of heartwater-endemic areas in Africa are at risk.

However, serological cross-reactions between *Ehrlichia* species have also been reported. As far as the MAP1-B ELISA is concerned, the assay does not detect antibodies to known ehr-
lichial agents infecting domestic ruminants, such as *E. bovis* and *E. ovina*, but antibodies are detected against *E. canis* (which infects dogs) and *E. chaffeensis* (a human pathogen) (21). Although the MAPI-B ELISA has been shown to perform satisfactorily for small ruminants, cross-reactions with unknown *Ehrlichia* species have been detected based on levels of seropositivity among sheep and goats in *Amblyomma*-free areas in South Africa and Zimbabwe (5, 13, 15). Similar *Ehrlichia* species of low pathogenicity may occur in The Gambia, since they have been found in neighboring Senegal (9). Such cross-reactions may falsely indicate previous exposure to heartwater, whereas in fact such animals are highly susceptible, and thereby the risk of small ruminants contracting the disease is underestimated.

In conclusion, our serological results in conjunction with recorded cases of heartwater-related mortalities indicate that *E. ruminantium* is widespread in The Gambia, and this poses a threat to susceptible livestock species. An estimated 50% of the sheep and 70% of the goats have not been exposed to *E. ruminantium* infection and constitute a group at risk from the disease. There appears to be a gradient of risk for livestock, increasing from the eastern part of the country towards the western coastal region. This gradient may be positively correlated with the distribution of *A. variegatum* ticks on sheep and goats in the country; ticks were significantly lower in abundance in the eastern part of the country (0.01 tick per animal) than in the western part (0.76 tick per animal) (B. Faburay et al., unpublished data). It is recommended that, in future livestock-upgrading programs in The Gambia, susceptible small ruminants should be protected by prophylactic treatment using oxytetracyclines or vaccination using attenuated or inactivated rickettsiae, possibly in conjunction with tick control, prior to their translocation from the eastern to the western region of the country.
