A theoretical analysis of the odd generalized exponentiated inverse Lomax distribution

Abstract

A four parameter compound continuous distribution for modeling lifetime data known as the Odd Generalized Exponentiated Inverse Lomax distribution was proposed in this study. Basic structural properties were derived in minute details.

Keywords: odd generalized Exponentiated family, inverse lomax distribution, moments, reliability function, hazard function, continuous distribution

Introduction

Various distributions have been proposed to serve as models for wide applications on data from different real-life situations through the extension of existing distribution. This has been achieved in various ways. The Lomax distribution also called “Pareto type II” is a special case of the generalized beta distribution of the second kind, and can be seen in many application areas, such as actuarial science, economics, biological sciences, engineering, lifetime and reliability modeling and so on. This heavy duty distribution is considered useful as an alternative distribution to survival problems and life-testing in engineering and survival analysis. Inverse Lomax distribution is a member of the inverted family of distributions and discovered to be very flexible in analyzing situations with a realized non-monotonic failure rate. If a random variable X has a Lomax distribution, then Y = 1/X has an inverse Lomax Distribution. Thus, a random variable X is said to have an Inverted Lomax distribution if the corresponding probability density function and cumulative density function are given by: 

$$g(x; \alpha, \beta) = \frac{\beta}{x^2} \left(1 + \frac{\beta}{x}\right)^{-\alpha - 1}; x \geq 0, \alpha, \beta > 0 \quad (1)$$

$$G(x) = \left(1 + \frac{\beta}{x}\right)^{-\alpha}; x \geq 0, \alpha, \beta > 0 \quad (2)$$

In literature exist several family of distribution and the references to them are listed in Alizadeh et al. In the course of this study, the Odd Generalized Exponential family of distribution developed by Alizadeh having probability density and cumulative distribution function given by:

$$f(x) = \frac{abg(x)}{1 - G(x)} e^{-\alpha + \alpha G(x)} \left(1 - e^{-\alpha G(x)}\right)^{\alpha - 1}; a, b > 0 \quad (3)$$

$$F(x) = \left(1 - e^{-\alpha G(x)}\right)^\alpha; a, b > 0 \quad (4)$$

was used to extend the Inverse Lomax distribution. The goal is to derive a continuous compound distribution that would be robust and tractable than the Inverse Lomax distribution. The rest of the article is structured as follows: In section 2, we derive the cumulative distribution function, probability density function, reliability function, hazard function, reverse hazard function, and cumulative hazard function of the Odd Generalized Exponentiated Inverse Lomax distribution, and present their respective plots for different values of the parameter. In minute details, we establish the structural properties, which include the asymptotic behavior, moments, quantile function, median, skewness and kurtosis, in section 3. In section 4, we determined the order statistics and the estimate of the unknown parameter using maximum likelihood estimation techniques. Application to two different lifetime dataset and a conclusion is made in section 5.

The Odd Generalized Exponentiated Inverse Lomax (OGE-IL) distribution

A four parameter Odd Generalized Exponentiated Inverse Lomax distribution was investigated in this section. Obtained by substituting equation (2) into (4), the cumulative distribution function of the OGE-IL distribution is given by:

$$F_{OGE-IL}(x) = 1 - e^{-\alpha \left(1 + \frac{\beta}{x}\right)^{-\alpha}}; \alpha, \beta, a, b > 0 \quad (5)$$

The corresponding probability density function is given by:

$$f_{OGE-IL}(x) = \frac{abf(x)}{x^2 \left(1 + \frac{\beta}{x}\right)^{\alpha - 1} \left(1 - e^{-\alpha \left(1 + \frac{\beta}{x}\right)^{-\alpha}}\right)^{\alpha - 1}}; a, \beta, a, b > 0 \quad (6)$$

The reliability function is given by;
A theoretical analysis of the odd generalized exponentiated inverse Lomax distribution

\[ S_{OGE-IL}(x) = 1 - \left[ 1 - e^{-\left( \frac{1+x}{\tau} \right)^\alpha} \right]^\beta \] \quad \alpha, \beta, a, b > 0 \quad (7)

The failure rate function/hazard function is given by;

\[ h_{OGE-IL}(x) = \frac{ab \left( 1 + \frac{\beta}{x} \right)^{1+\alpha} e^{-\left( \frac{1+x}{\tau} \right)^\alpha} \left( \frac{1+x}{\tau} \right)^{-\alpha} - e^{-\left( \frac{1+x}{\tau} \right)^\alpha}} {1 - e^{-\left( \frac{1+x}{\tau} \right)^\alpha}} \] \quad \alpha, \beta, a, b > 0 \quad (8)

The reverse hazard function is given by;

\[ r_{OGE-IL}(x) = \frac{ab \left( 1 + \frac{\beta}{x} \right)^{1-\alpha} e^{-\left( \frac{1+x}{\tau} \right)^\alpha} \left( \frac{1+x}{\tau} \right)^{-\alpha} - e^{-\left( \frac{1+x}{\tau} \right)^\alpha}} {1 - e^{-\left( \frac{1+x}{\tau} \right)^\alpha}} \] \quad \alpha, \beta, a, b > 0 \quad (9)

The cumulative hazard function is given by;

\[ H_{OGE-IL}(x) = -\log \left[ 1 - e^{-\left( \frac{1+x}{\tau} \right)^\alpha} \right] \] \quad \alpha, \beta, a, b > 0 \quad (10)

And the odd function is given by;

\[ O_{OGE-IL}(x) = \frac{\left[ \left( \frac{1+x}{\tau} \right)^\alpha - 1 \right] \left( \frac{1+x}{\tau} \right)^{-\alpha}} {1 - 1 - e^{-\left( \frac{1+x}{\tau} \right)^\alpha}} \] \quad \alpha, \beta, a, b > 0 \quad (11)

The respective plots of the probability density function, cumulative distribution function, reliability function, and the hazard functions for different parameter values are represented in Figure 1–4.

Structural Properties of the Odd Generalized Exponentiated Inverse Lomax (OGE-IL) distribution

In this section we derive some of the basic theoretical/structural properties of the OGE-IL distribution, such as; its asymptotic behavior, quantile, median, Skewness and kurtosis of the Odd Generalized Exponentiated Inverse Lomax distribution.

Asymptotic Behavior of the OGE-IL Distribution

We examine the behavior of the OGE-IL distribution in equation (6) as \( x \to \infty \) and as \( x \to -\infty \) and in equation (10) as i.e. \( x \to \infty \)

\[
\lim \left. f_{OGE-IL}(x) \right|_{x=\infty} = \lim_{x \to \infty} \frac{\alpha \beta}{x^2} e^{-\frac{\alpha^\beta}{x^2}(1 + e^{-\alpha x})} = 0
\]

\[
\lim \left. f_{OGE-IL}(x) \right|_{x=-\infty} = \lim_{x \to -\infty} \frac{\alpha \beta}{x^2} e^{-\frac{\alpha^\beta}{x^2}(1 - e^{-\alpha x})} = 0
\]

Thus showing that the Odd Generalized Exponentiated Inverse Lomax distribution is unimodal i.e. it has only one mode.

We can also deduce that for the OGE-IL Distribution, \( \lim_{x \to \infty} F(x) = 1 \) i.e.

\[
\lim_{x \to \infty} 1 - e^{-\frac{\alpha^\beta}{x^2}(1 + e^{-\alpha x})} = 1
\]

Thus indicating that the OGE-IL distribution has a proper probability density function.

Quantile function and Median

\[
Q_{OGE-IL}(u) = F_{OGE-IL}^{-1}(u)
\]

Let \( u = 1 - e^{-\frac{(1 + \beta x^a)}{1^a}} \)

\[
u/a = 1 - e^{-\frac{(1 + \beta x^a)}{1^a}}
\]

\[
\ln\left(1 + u^{1/a}\right) = -b \left(\frac{1 + \beta x^a}{1 - 1 + \beta x^a}\right)
\]

\[
-\ln\left(1 + u^{1/a}\right) = -b \left(\frac{1 + \beta x^a}{1 - 1 + \beta x^a}\right)
\]

\[
1 + \frac{1}{u^{1/a}} = e^{-\frac{(1 + \beta x^a)}{1^a}}
\]

The Quantile function of the Odd Generalized Exponentiated Inverse Lomax distribution is;

\[
Q(u) = \beta \left[\frac{-\ln\left(1 + u^{1/a}\right)}{b - \ln\left(1 + u^{1/a}\right)}\right]^{-1}
\]

The median of the Odd Generalized Exponentiated Inverse Lomax distribution can be gotten by placing \( u \) as 0.5 in equation (12) above, we obtain

\[
\text{median} = \beta \left[\frac{-\ln\left(1 + 0.5^{1/a}\right)}{b - \ln\left(1 + 0.5^{1/a}\right)}\right]^{-1}
\]
Skewness and Kurtosis

According to Kenney & Keeping, the Bowely Quartile Skewness is given as:

\[ S_q = \frac{q_{0.75} - 2q_{0.5} + q_{0.25}}{q_{0.75} - q_{0.25}} \]  

(13)

Moors quantile based Kurtosis by Moors [10] is given as:

\[ K_q = \frac{q_{0.875} - q_{0.625} - q_{0.375} + q_{0.25}}{q_{0.75} - q_{0.25}} \]  

(14)

\[ \mu_i = \sum_{k=0}^{n} \binom{a-1}{k} \frac{1}{(1 + \beta x)^{a}} \left( 1 + \frac{\beta}{x} \right)^{-(a+1)} \]  

(15)

The minimum order statistics for the OGE-IL distribution is given as;

\[ f_n(x) = \frac{n!}{(1-n)(n-j)} \left( \alpha x \beta \right)^{-(1-a)} \left( 1 - \frac{1}{1 + \beta x} \right)^{a-1} \left( 1 - e^{-\frac{1}{1 + \beta x}} \right)^{j-1} \]  

(16)

The minimum order statistics for the OGE-IL distribution is given as;

\[ f_{\min}(x) = \frac{n}{x^2 \left( 1 + \beta x \right)^{-(a-1)}} \left( 1 - e^{-\frac{1}{1 + \beta x}} \right)^{a-1} \left( 1 - \frac{1}{1 + \beta x} \right)^{j-1} \]  

(17)

And the maximum order statistics for the OGE-IL distribution is given as;

\[ f_{\max}(x) = \frac{n}{x^2 \left( 1 + \beta x \right)^{-(a-1)}} \left( 1 - e^{-\frac{1}{1 + \beta x}} \right)^{a-1} \left( 1 - \frac{1}{1 + \beta x} \right)^{j-1} \]  

(18)

Parameter estimation

Using maximum likelihood estimation techniques, Let \( X_1 \ldots X_n \) indicate a random sample of the complete OGE-ILD data, and then the sample’s likelihood function is given as;

\[ L = \prod_{i=1}^{n} f(x; \alpha, \beta, a, b) \]

\[ L(x; \alpha, \beta, a, b) = \prod_{i=1}^{n} \left( \frac{ab\beta \left( 1 + \beta x \right)^{-(1-a)}}{x^2 \left( 1 + \beta x \right)^{-(a-1)}} \left( 1 - e^{-\frac{1}{1 + \beta x}} \right)^{a-1} \right) \]  

Citation: Maxwell O, Friday AI, Chukwudike NC, et al. A theoretical analysis of the odd generalized exponentiated inverse Lomax distribution. Biom Biostat Int J. 2019;8(1):17-22. DOI: 10.15406/bbiq.2019.08.00264
Thus the log likelihood function becomes;

$$L(x; \alpha, \beta, a, b) = n \ln \alpha + n \ln \beta + n \ln a + n \ln b - 2 \sum_{i=1}^{n} \left[\ln x_i - 2 \sum_{i=1}^{n} \left\{ \left[1 + \frac{\beta}{x_i} \right] - (\alpha - 1) \sum_{i=1}^{n} \left[1 + \frac{\beta}{x_i} \right]^{-a} \left[1 - e^{-\left(1 + \frac{\beta}{x_i} \right)^{-a}} \right] \right\} \right]$$

(19)

By taking the derivative with respect to $\alpha, \beta, a, b$, and equating to zero, we have;

$$\frac{\partial \ln L(x)}{\partial \beta} = \frac{n}{\beta} \sum_{i=1}^{n} \left( 1 + \frac{\beta}{x_i} \right) - (\alpha - 1) \sum_{i=1}^{n} \left[1 + \frac{\beta}{x_i} \right]^{-a} \left[1 - e^{-\left(1 + \frac{\beta}{x_i} \right)^{-a}} \right] \left( x + \beta \right) \left( 1 + \frac{\beta}{x_i} \right)^{-a} = 0$$

(20)

$$\frac{\partial \ln L(x)}{\partial a} = -\frac{\alpha}{a} = 0$$

(21)

$$\frac{\partial \ln L(x)}{\partial b} = \frac{n}{b} \sum_{i=1}^{n} \left[1 - e^{-\left(1 + \frac{\beta}{x_i} \right)^{-a}} \right] = 0$$

(22)

The parameters of the OGE-IL distribution is obtained by solving equation 20-24.

**Conclusion**

Using the Odd Generalized Exponential family of distribution, we have successfully extended the Inverse Lomax distribution from a two parameter to a four parameter distribution. Densities and theoretical characteristics for the proposed OGE-IL distribution have been derived.
