The synthesis of two new 9-phenylacridino-18-crown-6 ether type sensor molecules \([1\text{ and } (R,R)-2]\) was accomplished. The cation recognition ability of the achiral sensor molecule \(1\) towards various ions was studied in acetonitrile by UV/Vis and fluorescence spectroscopies. Our studies revealed the binding of Ag\(^{+}\), Cd\(^{2+}\), Ni\(^{2+}\), Pb\(^{2+}\), Zn\(^{2+}\) and NH\(^{4+}\) ions by the latter molecule. Selectivity of the chiral dimethyl-substituted analogue \((R,R)-2\) was studied toward the enantiomers of the hydrogen perchlorate salts of 1-phenylethylamine, 1-(1-naphthyl)ethylamine, phenylglycine methyl ester and phenylalanine methyl ester using fluorescence spectroscopy.

**Keywords**
crown compounds, UV/Vis spectroscopy, fluorescence spectroscopy, metal complexes, enantiomeric recognition

**1 Introduction**
Since Pedersen reported the preparation and studies of the first crown ethers \([1, 2]\) these host molecules have gained much attention \([3, 4]\). The selectivity of crown ethers is based on a generally occurring vital phenomenon called molecular recognition, which is governed by non-covalent intermolecular forces, such as hydrogen bonding, \(\pi-\pi\) interaction \([5, 6]\) and cation-\(\pi\) interaction \([7, 8]\), taking place between host and guest molecules. As a good example the selective metal ion binding and transport of natural ionophores through biological membranes can be mentioned.

The enantioselective complexing ability of chiral macrocycles is based on enantiomeric recognition, which is a special case of molecular recognition involving the discrimination between the enantiomers of a chiral guest molecule by a chiral host molecule. The discriminating ability of crown ether-based sensor molecules, toward various cations and the enantiomers of chiral compounds, has been studied by UV/Vis and fluorescence spectroscopies \([9-17]\). Several optically active macrocycles have been used as enantioselective selector molecules in transport studies \([18]\), in capillary electrophoresis \([19]\) and in liquid chromatography \([20-25]\).

We have reported the preparation and evaluation of an enantiopure pyridino-crown ether-based chiral stationary phase (CSP) in which the pyridine ring was substituted with a phenyl group \([23]\). This CSP showed the best values for the separation of the mixtures of enantiomers of protonated primary aralkyl amines among all the enantiopure pyridino-crown ether-based CSPs \([21-23]\). The substitution increased the strength of the \(\pi-\pi\) interaction between the pyridino-crown ether and the aromatic groups of the guest molecules, and by this expectedly enhanced the degree of enantiomeric recognition. By incorporating a more extended aromatic system into the crown ether macroring, for example an acridine unit, the ability of creating strong \(\pi-\pi\) interactions or cation-\(\pi\) interactions with guest molecules can be enhanced \([16, 17, 24, 25]\). Apart from the ability of creating stronger secondary interactions, the tricyclic ring system makes the crown ether framework more rigid, resulting in improved selectivity. We studied the complexation ability of crown ether...
type sensors containing an acridine fluorophore unit \([(R,R)-3, (R,R)-4 \text{ and } (S,S)-5\), see Fig. 1] toward the enantiomers of 1-phenylethylamine hydrogen perchlorate (PEA), 1-(1-naphthyl)ethylamine hydrogen perchlorate (1-NEA), phenylglycine methyl ester hydrogen perchlorate (PGME) and phenylalanine methyl ester hydrogen perchlorate (PAME) by UV/Vis and fluorescence spectroscopies [16]. An aromatic unit connected to the acridine ring at position 9 may further increase the degree of complexation.

In this paper we report the preparation of two new 9-phenylacridino-18-crown-6 ether type sensors 1 and \((R,R)-2\) (Fig. 1). The cation recognition ability of the achiral sensor compound 1 toward various ions was studied by UV/Vis and fluorescence spectroscopies. The enantiomeric discrimination ability of the dimethyl-substituted analogue \((R,R)-2\) was studied towards the enantiomers of PEA, 1-NEA, PGME and PAME (Fig. 2) using fluorescence spectroscopy.

2 Results and Discussion

2.1 Synthesis

The new 9-phenylacridino-18-crown-6 ethers 1 and \((R,R)-2\) were prepared by the macrocyclization reaction of 9-phenylacridine-4,5-diol (6) and ditosylate 7 or \((S,S)-8\) in the presence of potassium carbonate in DMF, as outlined in Scheme 1. Ditosylates 7 and \((S,S)-8\) were obtained as reported [26, 27].

![Scheme 1 Synthesis of novel 9-phenylacridino-18-crown-6 ethers 1 and \((R,R)-2\).](image)

9-Phenylacridine-4,5-diol (6) was prepared in good yield by the O-demethylation of 4,5-dimethoxy-9-phenylacridine (9), using anhydrous aluminium chloride in dry and pure chlorobenzene (Scheme 2). Even higher yield was achieved for the latter transformation by using pyridinium chloride at elevated temperature (180°C). 4,5-Dimethoxy-9-phenylacridine (9) was obtained from 9-chloro-4,5-dimethoxyacridine (10) by the modification of the Kharasch reaction (other C-C coupling reactions such as Suzuki, Grignard and related reactions did not yield the desired product). The carbon-carbon coupling reaction was carried out with an excess of phenylmagnesium bromide in dry and pure THF and toluene. Tetrakis(triphenylphosphine)palladium(0) and dilithium tetrachlorocuprate were used as catalysts. By changing the order of additions of the reagents and using toluene instead of THF to dissolve chloro compound 10 a higher yield was achieved (see Experimental Section). Replacing tetrakis(triphenylphosphine)palladium(0) by palladium(II) acetate gave the highest yield (Scheme 2).

The relatively low yields may be attributed to sterical hindrance. 4,5-Dimethoxy-9(10H)-acridinone (11a) was also isolated as a byproduct in all C-C coupling reactions, meaning that the dehalogenation and oxidation of the chloro compound 10 took place. 9-Chloro-4,5-dimethoxyacridine was prepared from 4,5-dimethoxy-9(10H)-acridinone 11a [28] applying phosphoryl chloride (Scheme 2).

![Fig. 1 Schematics of the acridino-18-crown-6 ether host molecules.](image)

![Fig. 2 Optically active ammonium salt guests used in the enantiomeric recognition studies.](image)
Macrocycle 1 was also synthesized from the parent acridono-18-crown-6 ether (12) [28]. The latter crown ether (12) was first reacted with phosphoryl chloride and the crude 9-chloro derivative (13), without purification, was treated with phenylmagnesium bromide to afford macrocycle 1 (Scheme 3). The overall yield of this multistep reaction was lower than the one outlined in Schemes 1 and 2, therefore it was not applied for the preparation of chiral macrocycle (R,R)-2.

2.2 Complexation studies

The complexation ability of achiral sensor 1 was first studied by UV/Vis spectroscopy in acetonitrile toward the perchlorate salts of various metal ions (Ag\(^{+}\), Ca\(^{2+}\), Cd\(^{2+}\), K\(^{+}\), Mg\(^{2+}\), Na\(^{+}\), Ni\(^{2+}\), Pb\(^{2+}\), Zn\(^{2+}\)), ammonium perchlorate and benzylammonium perchlorate. The UV/Vis spectra of ligand 1 did not show any changes upon addition of a twentyfold excess of Ca\(^{2+}\), K\(^{+}\), Mg\(^{2+}\), Na\(^{+}\) and benzylammonium ions. This suggests the lack of complexation or the formation of complexes with low stabilities. However, a bathochromic shift of the absorption spectra was observed in the cases of Ag\(^{+}\), Cd\(^{2+}\), Ni\(^{2+}\), Pb\(^{2+}\), Zn\(^{2+}\) and NH\(_{4}^{+}\). The absorption spectra of ligand 1 and its complexes are represented in Fig. 3.

Fluorescence titration was also performed in order to determine the stability constants (K\(_{s}\)) and stoichiometry of the complexes. In all cases, with the exception of Cd\(^{2+}\), the fluorescence emission spectra showed a decrease upon addition of the salts, which means that the fluorescence was quenched by complex formation, as a typical example see Fig. 4. In the case of Cd\(^{2+}\), a red shift of the spectra was observed (Fig. 5). In the case of Cd\(^{2+}\) ions the complex formed by the achiral crown ether and the Cd\(^{2+}\) ions may have caused significant conformational changes, which resulted in different photophysical behavior compared to the other complexed ions.

Upon being treated with different ions the fluorescence changes of the sensor followed the Benesi-Hildebrand equation [29, 30] therefore we could assume the formation of complexes with 1:1 ligand to metal ion ratios. The changes in the spectra were further analyzed using nonlinear regression analysis, all of the titration series of the spectra could be fitted satisfactorily using a complex form with 1:1 stoichiometry. The logK values determined by the global nonlinear regression analysis are represented in Table 1. Sensor 1 formed the most stable complexes with Cd\(^{2+}\), Pb\(^{2+}\), Zn\(^{2+}\) and NH\(_{4}^{+}\) (Table 1). Pb\(^{2+}\), Zn\(^{2+}\) and NH\(_{4}^{+}\) caused the fluorescence emission to decrease, as shown for Ag\(^{+}\) in Fig. 4, but in the case of Cd\(^{2+}\) a significant bathochromic shift could be observed (Fig. 5).
Table 1 Stability constants for 1:1 stoichiometric complexes of 1 with Ag⁺, Cd²⁺, Ni²⁺, Pb²⁺, Zn²⁺ and NH₄⁺ in MeCN.

| Ion   | Ag⁺  | Cd²⁺ | Ni²⁺ | Pb²⁺ | Zn²⁺ | NH₄⁺ |
|-------|------|------|------|------|------|------|
| logK  | 2.43 | 4.86 | 2.48 | 5.07 | 4.32 | 5.73 |

Table 2 Stability constants and enantioselectivity of the complexes of (R,R)-2 with the enantiomers of PEA, 1-NEA, PGME and PAME in MeCN.

| Guest | logK  | ∆logK |
|-------|------|-------|
| (R)-PEA | 4.42 | +0.31 |
| (S)-PEA | 4.73 |       |
| (R)-1-NEA | 4.78 | +0.46 |
| (S)-1-NEA | 5.24 |       |
| (R)-PGME | 4.91 | -0.24 |
| (S)-PGME | 4.67 |       |
| (R)-PAME | 3.87 | +0.11 |
| (S)-PAME | 3.98 |       |

The enantiomeric discrimination of the dimethyl-substituted acridino-18-crown-6 ethers (R,R)-3, (S,S)-5 and the diisobutyl-substituted analogue (R,R)-4 toward the enantiomers of the perchlorate salts of primary aralkylamines and α-amino acid esters was studied by Kertész and coworkers [16]. We anticipated that the substitution of the acridine ring at position 9 with an aromatic unit may further increase the degree of enantiomeric recognition. Thus, the enantioselectivity of the novel dimethyl-substituted 9-phenyl-acridino-18-crown-6 sensor molecule (R,R)-2 was studied toward the enantiomers of PEA, 1-NEA, PGME and PAME using UV/Vis and fluorescence spectroscopies. The absorbances of ligand (R,R)-2 were essentially unchanged upon titration with the enantiomers of the above optically active salts. However, the fluorescence emission spectra showed a relatively large decrease upon addition of the guest molecules. This means that the fluorescence was significantly quenched in the complexes (Figs. 6 and 7).

The results clearly demonstrate that in the cases of the enantiomers of PEA, 1-NEA and PGME the enantiomeric recognition ability of the dimethyl-substituted sensor (R,R)-2 is similar to that of the earlier reported [16] macrocycles [(R,R)-3, (R,R)-4 and (S,S)-5] containing methyl and isobutyl groups at their stereogenic centers. For the enantiomers of PAME the stability constants of (R,R)-2 are smaller. However, the degree of enantiomeric recognition (ΔlogK values in Table 2) are higher in the cases of PEA and 1-NEA for (R,R)-2. Moreover, the selectivity toward the enantiomers of PGME of the dimethyl substituted (R,R)-2 is comparable to that of the reported [16] diisobutyl-substituted (R,R)-4. This can be attributed to the increased bulkiness of (R,R)-2, meaning that sterical hindrance probably play a vital role in enantioselectivity. It was found for the studied primary amines (PEA and 1-NEA) that in all cases the (S)-enantiomer formed a more stable complex with (R,R)-2 than the (R)-enantiomer, demonstrating the generally observed higher stability of heterochiral complexes [(R,R)-crown ether–(S)-ammonium salt] compared to that of homochiral complexes [(R,R)-crown ether–(R)-ammonium salt]. This behavior is in unison with the earlier observations using acridino-crown ether
based sensors and selectors [16, 24, 25]. Kertész and coworkers showed [16] that in the case of PGME the homochiral complex had higher stability, which was also observed by us. This phenomenon was attributed [16] to the fact that, based on the Cahn-Ingold-Prelog naming system, (R)-PEA, (R)-1-NEA, (S)-PGME and (S)-PAME have the same spatial arrangement. In our case PAME showed unusual behavior, the complex formed by (R,R)-2 and (S)-PAME had higher stability than the complex of (R,R)-2 and (R)-PAME, this behavior can again [16] be attributed to the structural difference of PAME compared to the other salts, namely the presence of an additional methylene unit between the stereogenic centre and the aromatic ring (Fig. 2).

3 Experimental

3.1 Chemicals and solvents

Starting materials and reagents were purchased from Sigma–Aldrich Corporation unless otherwise noted. Silica Gel 60 F_{254} (Merck) and aluminium oxide 60 F_{254} neutral type E (Merck) plates were used for TLC. Aluminium oxide (neutral, activated, Brockman I) and Silica Gel 60 (70–230 mesh, Merck) were used for column chromatography. Ratios of solvents for the eluents are given in volumes (cm³/cm³). Solvents were dried and purified according to well established methods [31]. Evaporations were carried out under reduced pressure unless otherwise stated.

3.2 Apparatus

Melting points were taken on a Boetius micro-melting point apparatus. Infrared spectra were recorded on a Bruker Alpha-T FT-IR spectrometer using KBr pastilles. Optical rotations were taken on a Perkin-Elmer 241 polarimeter that was calibrated by measuring the optical rotations of both enantiomers of menthol. NMR spectra were recorded on a Bruker 300 Avance spectrometer (at 300 MHz for ¹H and at 75.5 MHz for ¹³C spectra). HRMS analyses were performed on a LTQ FT Ultra (Thermo Fisher Scientific, Bremen, Germany) system. The ionization method was ESI and operated in positive ion mode. The protonated molecular ion peaks were fragmented by CID at a normalized collision energy of 45-65%. The samples were solved in methanol. Data acquisition and analysis were accomplished with Xcalibur software version 2.0 (Thermo Fisher Scientific). UV/Vis spectra were taken on a Multiskan Spectrum Microplate Spectrophotometer controlled by SkanIt Software for Multiscan version 2.1. Fluorescence spectra were recorded on a BMG Labtech CLARIOstar spectrophotometer. Spectrophotometric titrations were carried out according to the literature [27]. The stability constants of the complexes were determined by global nonlinear regression analysis using the ReactLab™ Equilibria spectral analyses suite (Jplus Consulting, www. jplusconsulting.com). The concentrations of the solutions of sensors 1 and (R,R)-2 were 50 µM for the UV-vis measurements and 10 µM in the case of ligand 1 or 20 µM in the case of (R,R)-2 for the fluorescence titrations.

3.3 Synthesis of the new compounds

3.3.1 23-Phenyl-6,7,9,10,12,13,15,16-octahydro-1,21-methenobenzo[n][1,4,7,10,13,16]pentaoxazacyclooctadecine (C₇H₇NO₅)

3.3.1.1 Procedure A) Starting from 9-phenylacridine-4,5-diol (6)

A mixture of 9-phenylacridine-4,5-diol (6, 130 mg, 0.45 mmol), tetraethylene glycol ditosylate [26] (7, 250 mg, 0.5 mmol) and K₂CO₃ (520 mg, 3.76 mmol) in DMF (40 cm³) was vigorously stirred under Ar at 50°C for 48h. The reaction mixture was cooled to rt and the solvent was removed. The residue was taken up in water (100 cm³) and CHCl₃ (100 cm³). The phases were shaken well and separated. The aqueous phase was extracted with CHCl₃ (4 × 50 cm³). The combined organic phase was shaken with saturated brine (50 cm³), dried over MgSO₄, filtered and the solvent was evaporated. The crude product was purified by column chromatography on neutral aluminium oxide using 1:30 EtOH/toluene mixture as an eluent to gain I (88 mg, 44%) as yellow crystals. Rₚ = 0.3 (alumina TLC, 1:30 EtOH–toluene); M.p.: 63–65°C; IR (KBr) ν max = 3073, 3042, 2931, 2870, 2856, 1623, 1565, 1472, 1449, 1413, 1355, 1347, 1275, 1238, 1110, 936, 753, 741, 705 cm⁻¹; ¹H NMR (300 MHz, CDCl₃) δ = 3.81–3.88 (m, 4H, OCH₂), 4.19–4.28 (m, 4H, OCH₂), 7.01 (d, J = 8 Hz, 2H, Ar-H), 7.21 (d, J = 8 Hz, 2H, Ar-H), 7.27–7.33 (m, 2H, Ar-H), 7.37–7.44 (m, 2H, Ar-H), 7.53–7.62 (m, 3H, Ar-H) ppm; ¹³C NMR (75 MHz, CDCl₃) δ = 68.82, 68.84, 70.46, 71.42 (OCH₂), 107.40, 118.84, 126.03, 126.10, 126.59, 128.44, 128.52, 130.45, 136.53, 140.48, 154.41 (Ar-C) ppm; HRMS m/z = 446.19595 (M+H)⁺ (calcd for C₇H₇NO₅, 445.18892).

3.3.1.2 Procedure B) starting from acridono-crown ether 12

To acridono-crown ether 12 [28] 2.5,8,11,14-pentaoxa-26-azatetracyclo[13.9.3.0.19,270.21,25]heptacosa-1(24),1,5,17,19,21(25),22-heptaene-20-one (100 mg, 0.26 mmol) was added phosphoryl chloride (2 cm³) and the resulting mixture was stirred at 80°C under Ar for 2 h. The volatile components were removed and the residue was taken up in water (200 m³) and the pH was adjusted to 10 by 25% solution of trimethylamine. The resulting aqueous phase was extracted with CHCl₃ (3 × 150 cm³). The combined organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product (13) was used for the preparation of crown ether 1 without purification. A solution of crude 13 (90 mg, 0.22 mmol) in dry and pure toluene (40 cm³) was added dropwise to a stirred suspension of phosphynagnesium bromide (3M in THF, 0.5 cm³, 1.5 mmol), Pd(OAc)₂ (2.5 mg, 0.0111 mmol), dilithium tetra-chloro cuprate (0.1M in THF, 0.1 cm³, 0.01 mmol) and dry and pure toluene (15 cm³) at rt under Ar. The resulting mixture was stirred for 5 h, then it was cooled down to 0°C. The solvent was removed and the residue was taken up in EtOAc (50 cm³) and
water (50 cm³). The phases were shaken well and separated. The aqueous phase was extracted with EtOAc (3 × 40 cm³). The combined organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product was purified by column chromatography on neutral aluminium oxide using 1:30 EtOH/toluene mixture as an eluent to gain 1 (11 mg, 11%), which was identical in every aspect to that prepared by the previous procedure (A).

### 3.3.2 (6R,16R)-6,16-Dimethyl-23-phenyl-6,7,9,10,12,13,15,16-octahydro-1,21-methenodibenzo[9,10]pentaazaacyclopentadecine [(R,R)-2, C₇₉H₇₉NO₂]

A mixture of 9-phenylacridine-4,5-diol (6, 130 mg, 0.45 mmol), ditosylate (S,S)-8 [27] (265 mg, 0.5 mmol), and finely powdered anhydrous K₂CO₃ (520 mg, 3.76 mmol) was stirred in dry and pure DMF (40 cm³) overnight vigorously under Ar at rt for 10 min and then at 50°C for six days. The solvent was removed and the residue was taken up in a mixture of water (70 cm³) and CH₂Cl₂ (70 cm³). The phases were shaken well and separated. The aqueous phase was extracted with CH₂Cl₂ (3 × 30 cm³). The combined organic phase was shaken with water (60 cm³), dried over MgSO₄, filtered, and the solvent was removed. The crude product was purified by PLC on neutral aluminium oxide using 1:40 EtOH/toluene as an eluent to gain [(R,R)-2, C₇₉H₇₉NO₂] (47 mg, 10%) as pale yellow crystals. Rf = 0.5 (alumina TLC, 1:20 EtOH–toluene); M.p.: 243–246°C; IR (KBr) νmax = 3075, 3052, 2923, 2875, 1624, 1567, 1467, 1411, 1377, 1340, 1274, 1259, 1231, 1097, 999, 935, 867, 831, 802, 757, 743, 708, 663 cm⁻¹; [α]D²⁵ = -15.1° c = 0.27 in MeOH; 1H NMR (300 MHz, CDCl₃) δ = 1.52 (d, J = 6 Hz, 6H, CH₃), 3.62–3.70 (m, 2H, OCH₂), 7.12 (d, J = 8 Hz, 2H, Ar-H), 7.18–7.34 (m, 4H, Ar-H), 7.37–7.45 (m, 2H, Ar-H), 7.43–7.48 (m, 2H, Ar-H), 7.59–7.66 (m, 3H, Ar-H) ppm; 13C NMR (75 MHz, CDCl₃) δ = 110.16, 117.72, 126.13, 127.03, 128.50, 128.73, 130.18, 135.60, 137.42, 137.44, 150.79 ppm; HRMS m/z = 288.10187 (M+H)⁺ (calcd for C₁₉H₁₅NO₂, 287.09463).

### 3.3.3 9-Phenylacridine-4,5-diol (6, C₇₉H₇₉NO₂)

#### 3.3.3.1 Procedure A

To a vigorously stirred suspension of anhydrous AlCl₃ (3.5 g, 26 mmol) in dry and pure chlorobenzene (40 cm³) was added 4,5-dimethoxy-9-phenylacridine (9, 85 mg, 0.27 mmol) at rt under Ar. The temperature of the reaction mixture was raised to 70°C and kept at this temperature for 3 h. The reaction mixture was cooled down to rt and it was poured into a vigorously stirred mixture of 37% aqueous HCl (3 cm³) and ice-water (100 cm³). The aqueous solution was extracted with CH₂Cl₂ (3 × 50 cm³). The combined organic phase was dried over MgSO₄, filtered and the solvent was removed. The crude product was purified by column chromatography on silica gel using 1:10 MeOH/CH₂Cl₂ mixture as an eluent to give 6 (63 mg, 81%) as orange crystals. Rf = 0.3 (silica gel TLC, 1:10 MeOH/CH₂Cl₂); M.p.: 200–204°C; IR (KBr) νmax = 3389, 3338, 3082, 3053, 2953, 2929, 2869, 1665, 1573, 1537, 1468, 1374, 1347, 1255, 1201, 1093, 855, 830, 749, 702, 669, 496 cm⁻¹; 1H NMR (300 MHz, CDCl₃) δ = 7.22–7.27 (m, 2H, Ar-H), 7.31–7.36 (m, 2H, Ar-H), 7.37–7.42 (m, 2H, Ar-H), 7.43–7.48 (m, 2H, Ar-H), 7.59–7.66 (m, 3H, Ar-H) ppm; 13C NMR (75 MHz, CDCl₃) δ = 110.16, 117.72, 126.13, 127.03, 128.50, 128.73, 130.18, 135.60, 137.42, 137.44, 150.79 ppm; HRMS m/z = 288.10187 (M+H)⁺ (calcd for C₁₉H₁₅NO₂, 287.09463).

### 3.3.3.2 (6R,16R)-6,16-Dimethyl-23-phenyl-6,7,9,10,12,13,15,16-octahydro-1,21-methenodibenzo[9,10]pentaazaacyclopentadecine [(R,R)-2, C₇₉H₇₉NO₂]

#### 3.3.3.2 Procedure B

4,5-Dimethoxy-9-phenylacridine 9 (220 mg, 0.7 mmol) and pyridinium chloride (4.8 g, 41 mmol) was stirred at 180°C for 2h. After the reaction was completed, the mixture was cooled down to rt and it was mixed with water (100 cm³). The aqueous solution was extracted with CH₂Cl₂ (3 × 100 cm³). The combined organic phase was dried over MgSO₄, filtered and the solvent was removed. The crude product was purified by column chromatography on silica gel using 1:10 MeOH/CH₂Cl₂ mixture as an eluent to give 6 (180 mg, 90%), which had the same physical properties and spectroscopic data as the one prepared with the above described (A) procedure.

### 3.3.4 4,5-Dimethoxy-9-phenylacridine (9, C₇₉H₇₉NO₂)

#### 3.3.4.1 Procedure A

A suspension of 9-chloro-4,5-dimethoxyacridine (10, 400 mg, 1.46 mmol), Pd(PPh₃)₄ (15 mg, 0.013 mmol), dillithium tetrachlorocuprate (0.1 M in THF, 0.2 cm³, 0.02 mmol) in dry and pure toluene (100 cm³) and dry and pure THF (50 cm³) was added dropwise to a stirred solution of phenylmagnesium bromide (3 M in THF, 3 cm³, 9.0 mmol) at rt under Ar. The reaction mixture was stirred for 4 h, then the solvent was removed. The residue was taken up in EtOAc (150 cm³) and water (150 cm³). The phases were shaken well and separated. The aqueous phase was extracted with EtOAc (3 × 100 cm³). The combined organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product was purified by column chromatography on silica gel using EtOAc as an eluent to give 9 (47 mg, 10%) as pale yellow crystals. Rf = 0.3 (silica gel TLC, EtOAc); M.p.: 243–246°C; IR (KBr) νmax = 3081, 3057, 3027, 2959, 2927, 2892, 2833, 1624, 1564, 1500, 1471, 1458, 1410, 1356, 1271, 1233, 1111, 1086, 1070, 977, 827, 748, 740, 697, 663, 629, 513 cm⁻¹; 1H NMR (300 MHz, CDCl₃) δ = 4.13 (s, 6H, OCH₂), 6.98 (d, J = 8 Hz, 2H, Ar-H), 7.20 (d, J = 8 Hz, 2H, Ar-H), 7.27–7.36 (m, 2H, Ar-H), 7.40–7.47 (m, 2H, Ar-H), 7.52–7.62 (m, 3H, Ar-H) ppm; 13C NMR (75 MHz, CDCl₃) δ = 56.08, 105.75, 118.26, 126.04, 126.47, 128.28, 128.45, 130.49, 136.71, 140.82, 146.52, 155.66 ppm; HRMS m/z = 316.13305 (M+H)⁺ (calcd for C₂₉H₂₂NO₂, 315.12593).
3.3.4.2 Procedure B)

A modification of the above described (A) procedure gave a better yield. A solution of 10 (750 mg, 2.74 mmol) and dry and pure toluene (200 cm$^3$) was added dropwise to a stirred suspension of phenylmagnesium bromide (3M in THF, 5.5 cm$^3$, 16.5 mmol), Pd(PPh$_3$)$_2$ (30 mg, 0.025 mmol), dilithium tetrachloro cuprate (0.1M in THF, 0.3 cm$^3$, 0.03 mmol) and dry and pure toluene (40 cm$^3$) at rt under Ar. The reaction mixture was stirred for 5 h at rt, then the solvent was removed. The residue was taken up in EtOAc (200 cm$^3$) and water (200 cm$^3$). The phases were shaken well and separated. The aqueous phase was filtered and the solvent was evaporated. The crude product was purified by column chromatography on silica gel using EtOAc as an eluent to give 9 (260 mg, 30%). This product (9) had the same physical properties and spectroscopic data as the one prepared by the above described (A) procedure.

3.3.4.3 Procedure C)

The highest yield was achieved by using Pd(OAc)$_2$ instead of Pd(PPh$_3$)$_2$. A solution of 10 (750 mg, 2.74 mmol) and in dry and pure toluene (200 cm$^3$) was added dropwise to a stirred suspension of phenylmagnesium bromide (3M in THF, 5.5 cm$^3$, 16.5 mmol), Pd(OAc)$_2$ (15 mg, 0.066 mmol), dilithium tetrachloro cuprate (0.1M in THF, 0.3 cm$^3$, 0.03 mmol) and dry and pure toluene (40 cm$^3$) at rt under Ar. The reaction mixture was stirred for 5 h at rt, then the solvent was removed. The residue was taken up in EtOAc (200 cm$^3$) and water (200 cm$^3$). The phases were shaken well and separated. The aqueous phase was filtered and EtOAc as an eluent to give 9 (400 mg, 46%), which had the same physical properties and spectroscopic data as the one prepared by the above described (A) procedure.

3.3.5 9-Chloro-4,5-dimethoxyacridine (10, C$_{15}$H$_{12}$ClNO$_2$)

A mixture of 4,5-dimethoxy-9(10H)-acridinone [28] (11, 3 g, 11.8 mmol) and phosphoryl chloride (45 cm$^3$) was vigorously stirred under Ar at 80°C for 3 hours. The reaction mixture was cooled to rt and the volatile components were removed. The residue was dissolved in CH$_2$Cl$_2$ (150 cm$^3$) and the cooled solution was treated with cold 25% aqueous trimethylamine solution (100 cm$^3$). The phases were shaken well and separated. The aqueous phase was extracted with CH$_2$Cl$_2$ (3 × 150 cm$^3$). The combined organic phase was shaken with saturated brine (100 cm$^3$), dried over MgSO$_4$, filtered and the solvent was evaporated. The crude product was triturated with hexane to give pure 10 (2.6 g, 81%) as brown crystals.

$R_f = 0.8$ (silica gel TLC, 1,4-dioxane); M.p.: 220–225°C (decomposition); IR (KBr) $\nu_{max} = 3438$, 3343, 3084, 3067, 3036, 3004, 2968, 2838, 1626, 1567, 1595, 1534, 1487, 1456, 1448, 1410, 1331, 1270, 1224, 1077, 971, 810, 746, 575 cm$^{-1}$; $^1$H NMR (300 MHz, CDCl$_3$) $\delta = 4.14$ (s, 6H, OCH$_3$), 7.06 (d, J = 8 Hz, 2H, Ar-H), 7.58 (t, J = 8 Hz, 2H, Ar-H), 7.99 (d, J = 8 Hz, 2H, Ar-H) ppm; $^{13}$C NMR (75 Hz, CDCl$_3$) $\delta = 56.42$, 106.84, 116.16, 125.86, 127.83, 140.67, 140.69, 155.66 ppm; HRMS m/z = 274.06292 (M+H)$^+$ (calcd for C$_{15}$H$_{12}$ClNO$_2$, 273.05566).

4 Conclusion

The synthesis and characterization of two new 9-phenylacridino-18-crown-6 ether type sensors [1 and (R,R)-2] was accomplished. The cation recognition ability towards various ions of the achiral sensor compound 1 was studied in acetonitrile by UV-vis and fluorescence spectroscopies. Our studies revealed the binding of Ag$^{+}$, Cd$^{2+}$, Ni$^{2+}$, Pb$^{2+}$, Zn$^{2+}$ and NH$_4^+$ ions by this sensor compound. We examined the enantiomeric recognition properties of the dimethyl-substituted ligand (R,R)-2 toward the enantiomers of protonated primary amines (PEA, 1-NEA) and amino acid derivatives (PGME, PAME) using fluorescence spectroscopy.

Experiments are in progress to prepare derivatives of sensor 1, which contain lipophilic side chains in order to prepare ion-selective electrodes. Thus, apart from the detection of ions, the measurement of their quantity may also be possible.

Also our further aim is to synthesize an analogue of (R,R)-2, which contains a carboxylic group at position 4 of the phenyl group. This functional group is suitable for a condensation reaction with 3-aminopropyltriethoxysilane, which gives the crown ether containing a triethoxysilane end group. The latter macrocycles can easily be attached to silica gel with covalent bonds to produce a new CSP.

Acknowledgement

Financial supports of the National Research, Development and Innovation Office, NKFIH (earlier OTKA) (NKFIH/OTKA K112289), of the New Széchenyi Development Plan (TÁMOP-4.2.1/B-09/1-KMR-2010-0002) are gratefully acknowledged.

The research has also been supported by the ÚNKP-16-3-III. New National Excellence Program of the Ministry of Human Capacities.
