2505. A Novel Mobile Phone Application for Remote Research Data Collection is Effective in Monitoring Chronic Sequelae After Acute Viral Infections

Yu Em Teh, MBBS, MRCP; Shirin Kaimuldin, MBBS, MRCP, MPH; Sze Chern Ang, BSc(Hons)1; Natalie Mei Ying Lee, BSc(Hons)2; Eng Eong Ooi, PhD1; Jenny Low, MBBS, MMed (Internal Medicine), MRCP (Internal Med), MPH3; Ram Saissekharam, B.S, M.S, PhD1; Shay Paintal, BS1 and Thomas Clark, B.S2; Infectious Diseases, Singapore General Hospital, Singapore, Singapore; Singapore General Hospital, Singapore, Singapore; 7Program in Emerging Infectious Diseases, Duke-NUS Graduate Medical School, Singapore, Singapore; Singapore-MIT Alliance for Research and Technology, Singapore, Singapore

Session: 255. Virology Potpourri Saturday, October 6, 2018: 12:30 PM

Background. Although much is known about the presentation of acute viral infections such as dengue fever, the long-term sequelae has not been systematically studied. Anecdotal evidence suggests that many viral infections, particularly flavivirus infections, may have long-term sequelae. Prospective longitudinal studies to evaluate such chronic health outcomes, however, require subjects to comply with multiple follow-up clinic visits, making them costly to run and vulnerable to high dropout rates. Using a mobile and other telehealth illnesses (OFI) as test cases, we aimed to explore the utility of a mobile phone application to evaluate the long-term sequelae and self-reported health outcomes in a cohort of patients up to one year post infection.

Methods. We designed a mobile phone Application for Information extraction in Dengue (MAIDEN) to study the long-term health outcomes of acute dengue compared with OFI. Demographic and clinical information was collected from the study participants at enrollment. Participants were sent a link via e-mail to download MAIDEN onto their mobile phone. For the day 1 visit, participants were not required to attend the study site in-person, but instead used MAIDEN to remotely enter information on their mobile phone. Except for the day 1 visit, participants were not required to attend the study site in-person, but instead used MAIDEN to remotely enter information on their mobile phone. Participants were sent a link via e-mail to download MAIDEN onto their mobile phone. Except for the day 1 visit, participants were not required to attend the study site in-person, but instead used MAIDEN to remotely enter information on their mobile phone.

Results. A total of 44 patients have been recruited to date. 4 participants had acute dengue infection and 40 had OFI. The overall study follow-up compliance rate was 89.2%. 23/44 patients have completed visits up till day 21. Of these 23 patients, 43% reported symptoms at day 7 and 39% at day 21. The table below shows the number of individual symptoms experienced by these participants.

| Symptom       | Dengue (n = 4) | OFI (n = 19) |
|---------------|---------------|-------------|
|               | Day 7 | Day 21 | Day 7 | Day 21 |
| Lack of energy| 1     | 1      | 8     | 4      |
| Inability to concentrate | 1     | 0      | 4     | 3      |
| Memory impairment | 1     | 0      | 2     | 1      |
| Headache      | 1     | 0      | 3     | 3      |
| Myalgia       | 1     | 1      | 1     | 3      |
| Arthralgia    | 1     | 0      | 2     | 1      |
| Anorexia      | 1     | 0      | 1     | 2      |

Disclosures. All authors: No reported disclosures.

Conclusion. Chronic symptoms continue to persist in a significant proportion of patients with acute viral illnesses. Mobile applications such as MAIDEN can serve as useful tools to support remote research data collection, making longitudinal follow-up of such patients feasible.

2506. Reactivation of Latent Cytomegalovirus Infection Following Major Surgery: Risk Factors and Outcomes

Katherine Herrick, BA1, Bradley Gardner, MBBS, FRACP, MS2; Rosemary Bailey, BS1; Jennifer Chow, MD, MS1 and David Snydman, MD, FIDSA3; Tufts University School of Medicine, Boston, Massachusetts; 4Department of Infectious Disease, Alfred Health & Monash University, Melbourne, Australia; 5Division of Geographic Medicine and Infectious Disease, Tufts Medical Center, Boston, Massachusetts

Session: 255. Virology Potpourri Saturday, October 6, 2018: 12:30 PM

Background. Reactivation of latent cytomegalovirus infection can occur in nonimmunocompromised individuals during critical illness and may be associated with increased morbidity and mortality. However, few studies have focused on patients undergoing major surgery. Our aim was to explore risk factors for and outcomes following reactivation in nonimmunocompromised post-operative patients.

Methods. We performed a retrospective case-control study of nonimmunocompromised patients with CMV reactivation following major surgery from 2004 to 2016. Cases included patients testing positive for CMV by viral load, viral culture or histopathology. Controls were matched to cases 2:1 by age, sex, type and year of surgery. Groups were compared using conditional logistic regression.

Results. 16 patients with CMV were matched to 32 controls. Median age was 65 (range 34–84) and 50% were male. The most common surgeries were abdominal (48%) and cardiac (25%). Median time from surgery to CMV diagnosis was 32 days (range 17–93). Patients had a range of clinical symptoms including fever (94%), hepatitis (75%), bone marrow suppression (56%) and gastrointestinal symptoms (56%). All except one were treated with anti-viral therapy. Despite having similar baseline Charlson comorbidity scores, cases were more likely to return to surgery within 3 months (odds ratio, OR 6.31; 95% CI, 1.29–30.74), require renal replacement therapy (OR 18.54, 2.36–145.6), total parenteral nutrition (OR 33.0, 6.60–262.37) and corticosteroids (OR 18.78, 4.5–103.9). Length of stay was increased (median 51 vs. 8 days, P = 0.005), confinements were more common (OR 15.10, 1.89–120.8), and in-hospital mortality was significantly higher (38% vs. 0%, P < 0.001).

Conclusion. Reactivation of CMV occurs in nonimmunocompromised patients post-operatively and is associated with poor outcomes including other infections and mortality. Potential risk factors include prolonged length of stay, development of surgical complications, and prolonged use of corticosteroids. It is not clear from our study if CMV reactivation is a surrogate marker of severe illness and postoperative complications, or if CMV reactivation plays a causative role in the development of these adverse outcomes.

2507. Active Norovirus Surveillance in Children Under 5 Years With Diarrhea Following Rotavirus Vaccine Introduction in Argentina

Angela Gentile, MD1; Juan Andrés Stupka, Bioch. MSc2; Juana Ignacio Degiuseppe, Bioch. MPH1; Maria Del Valle Juarez, MD2; Maria Florencia Lucion, MD2; Maria Turoc, PhD1; Liliana Sabaj MD3; Solana Rapaport, MD3 and Maria Soledad Areso, MD1; Epidemiology, Hospital de Niños “Ricardo Güiterrez”, Buenos Aires, Argentina, 1Viral Gastroenteritis Laboratory, INEI–ANLIS “Dr. Carlos G. Malbran”, Buenos Aires, Argentina, 2Bacteriology Laboratory, Hospital de Niños “Ricardo Güiterrez”, Buenos Aires, Argentina

Session: 255. Virology Potpourri Saturday, October 6, 2018: 12:30 PM

Background. Acute diarrhea is one of the main causes of infant mortality. Argentina introduced massive rotavirus vaccination in 2015. This introduction in several countries has been linked to a decrease in the rotavirus prevalence at the expense of an increase in norovirus (NoV) activity. NoV is reported to be emerging as one of the main agents producing acute diarrheal events in children under 5 years of age.

Methods. We performed a retrospective case–control study of nonimmunocompromised children with acute diarrhea in the city of Buenos Aires, Argentina, <5 years of age from January 2015 to December 2016. Controls were matched to cases 2:1 by age, sex and year of surgery. Cases included patients testing positive for NoV by viral load, viral culture or histopathology.

Results. A total of 136 patients were included and 125 stools were processed. The median of age was 20 months (IQR: 12–31) and 59% were male. The most common symptom was fever and vomiting in 70% and 55%, respectively. A 55% had watery diarrhea and 36% had abdominal pain. A 55% had episodes of vomiting and in 50% the duration of diarrhea was >3 days. NoV was detected in 30 of the 125 stools (24%), significantly more common in children <12 months old (P < 0.01).

Conclusion. In Argentina, there are few experiences estimating its prevalence in cases of acute diarrhea in children. The aim of this study was to analyze the role of NoV in outpatient children <5 years of age with acute diarrhea and their epidemiological pattern.

Disclosures. This work was supported by the Instituto de Salud Global de Buenos Aires (Argentina).
