Dislocation After Bipolar Hemiarthroplasty in Elderly Patient: A Case Report

Cokorda Gde Oka Dharmayuda, and Febyan

ABSTRACT

Total hip arthroplasty and hemiarthroplasty are two primary treatment choices for elderly patients with fractures or dislocations of the pelvic bone, as well as in fractures of the femoral neck. Dislocation of bipolar hemiarthroplasty is a rare postsurgical complication, but it can be a problem that requires acute management and is quite challenging to revise. We presented a case of an elderly patient with dislocation of hip bipolar hemiarthroplasty on the right side. The patient underwent a revision of total hip arthroplasty and had a satisfactory outcome. Mobilization began within two days after surgery. One-year follow-up revealed no occurrence of long-term complications.

Keywords: Bipolar hemiarthroplasty, dislocation, elderly patient, total hip arthroplasty.

I. INTRODUCTION

Bipolar hemiarthroplasty (BHA) is one of the surgical treatment choices for unstable fractures of the femoral neck in elderly patients, or as a secondary procedure after a failed attempt of internal fixation [1]. This procedure is advantageous because it provides an immediate full weight-bearing and a decreased reoperation rate, which subsequently reduces postoperative morbidity rates [2]. Hip dislocation after BHA prosthesis is rare but is a serious complication requiring an urgent open reduction and revision. The incidence of dislocation is not significantly different between unipolar and bipolar hemiarthroplasty [3]. Our study reported a case of the dislocated hip following the BHA surgery. Informed consent was obtained from the patient for publication of this case report and images for medical education purposes.

II. PRESENTATION OF CASE

A 70-year-old female patient presented to the emergency department with a chief complaint of right hip pain and a history of fall that occurred four months ago. Six months prior to the current visit, the patient had a history of right-sided femoral neck fracture and had undergone bipolar hemiarthroplasty surgery. Physical examination revealed shortening and external rotation on the affected limb, indicating hip dislocation. The patient also suffered pain on palpation and presented with a limited range of motion (active and passive movement). Laboratory tests revealed no abnormal findings. A plain radiograph was taken and demonstrated findings consistent with dislocation of the femoral head (Fig. 1). We informed the patient to be surgically treated by an open reduction followed by total hip arthroplasty (THA) and gained consent to perform the surgery. Revisional surgery was performed through the posterior approach. The femur was gathered anteriorly, followed by removing the existing bipolar hip arthroplasty implant. Ensure that the fibrous tissue had been removed thoroughly so that the acetabulum could be identified. Using an acetabular reamer, gently ream onto the remaining acetabular bone and place the implant within the acetabulum. The implant was later cemented onto proper positioning. Place the cerclage wire for the femoral bone and ream. Insert the long cemented femoral stem, and then the surgery was completed by reducing the hip. Subsequently, the patient was alert and presented with no further complication on postoperative radiograph follow-up (Fig. 2). Mobilization began within two days after surgery. We also recommended the patient undergo rehabilitation protocol. At one year of follow-up, the patient had no complaints and was able to carry out normal daily activities without any pain.
femoral offset [8]. Our patient also had a history of falling after surgery; thus, it became a traumatic factor that causes a direct force to the hip HA site.

The challenge of our case was the presence of fibrosis formation at the acetabulum surface, which occurred within four months throughout the dislocation. We cleared out the fibrosis formation and replaced the natural acetabulum with metal. Moriatity et al. [9] stated that the dislocated hip HA should be managed by open reduction and be converted to cemented THA. This study was supported by Fan et al., who performed revision surgery of BHA to THA with dual mobility cups, which showed an excellent postoperative result [10].

A comprehensive inspection of the acetabulum and adjacent structures for any defects or fractures should be performed, followed by examining the femoral stem for loosening and correct version. In our case, the patient had a well-fixed femoral stem with good alignment. We only prepared the Hastings femoral head component for the complete revision of the hemiarthroplasty components to prevent further dislocations.

IV. CONCLUSION

Surgical hip hemiarthroplasty in active elderly patients, especially those with a shallow acetabulum, is vulnerable to complications of hemiarthroplasty dislocation. The total hip arthroplasty should be considered to gain an excellent long-term surgical outcome and prevent further complications, including recurrence of dislocation.
