**Abstract:** The emergence of antimicrobial-resistant pathogens has significantly affected treatment outcomes for malasseziosis and pyoderma in dogs. Here, we determined the antimicrobial activity of plant-derived polyphenols against *Malassezia pachydermatis* and *S. intermedius*, the causative agents of malasseziosis and SIG infection, respectively. The polyphenols tested were castalagin, (+)-catechin, (−)-epigallocatechin, (−)-epicatechin gallate, (−)-epigallocatechin-3-O-gallate, myricitrin, prodelphinidin, procyanidin, resveratrol, rutin, theaflavin, and thearubigin. Minimum inhibitory concentration (MIC) values of these polyphenols against two yeast species, *M. pachydermatis* and *Candida albicans*, and two bacterial species, *S. intermedius* and *Achromobacter xylosoxidans*, were determined using an agar plate assay. Castalagin had the lowest MIC values against *M. pachydermatis* (100 μg/ml) and *S. intermedius* (50 μg/ml), suggesting its therapeutic potential for skin diseases caused by these microbes in dogs.

**Key words:** *malassezia pachydermatis*, polyphenols, *staphylococcus intermedius*
Malasseziosis, a common skin disease in dogs, is caused by *Malassezia* spp., which are part of the skin and mucosal microbiota. The *Staphylococcus intermedius* group (SIG) of bacteria comprises opportunistic pathogens that cause superficial pyoderma in dogs. Long-term use of antimicrobials is often required for treating chronic skin diseases caused by *M. pachydermatis* or SIG in dogs. Multiple antimicrobials may also be used to treat diseases caused by a combination of these microbes. Excessive use of antimicrobials may lead to the emergence of antimicrobial-resistant pathogens and alterations in the cutaneous or intestinal flora, that may preclude the use of appropriate antimicrobial therapies. The emergence of antimicrobial-resistant pathogens also significantly affects treatment outcomes, leading to the need for alternative treatment strategies.

Polyphenols are a subset of phenols bearing multiple hydroxyl groups on their aromatic components. Various polyphenol-containing veterinary dietary supplements are commercially available. These include plant-derived licorice glabra polyphenol (Glavonoid™, Kyoritsu Seiyaku, Tokyo, Japan) and lychee polyphenol (Oligonol®, Meiji Seika Pharma, Tokyo, Japan) which are mainly used as antioxidants. Polyphenols are also known to have antimicrobial activity against various bacterial species.

For the present study, it was hypothesized that plant-derived polyphenols would have antimicrobial activity.
against *M. pachydermatis* and *S. intermedius*. The aim of this study was to test this hypothesis by measuring the minimum inhibitory concentration (MIC) values.

Twelve kinds of polyphenols were used in this study (Fig. 1). These polyphenols were kindly provided by the Nagasaki University Graduate School of Biomedical Sciences (Table 1). The polyphenols were extracted from plants using the HPLC-based technique reported by Taguri et al.\(^8,9\). They were tested on two yeast species, *M. pachydermatis* and *Candida albicans*, and two bacterial species, *S. intermedius* and *Achromobacter xylosoxidans*. The yeasts and bacteria were obtained from the National Institute of Technology and Evaluation and the RIKEN BioResource Research Center (Table 2). Hinokiol, an essential oil derived from *Fallopia japonica* was used as a control.

Each polyphenol’s MIC value was determined using agar plate assays.\(^5\) Agar plates were prepared with polyphenol concentrations of 50–3,200 μg/ml in 60-mm sterile dishes. YM agar (formulated with 1% glucose, 0.5% peptone, 0.3% yeast extract, 0.3% malt extract, 1.5% agar, and pure water) and Mueller-Hinton agar (formulated with 30.0% peptone, 1.75% casein, 0.15% starch, 1.7% agar, and pure water) were used for the yeast and bacterial cultures, respectively. Each inoculum was prepared at a concentration of 1.0 × 10⁶ CFU/ml and streaked in a 20-mm line on the agar plates. The cultures were incubated for 48 h at 28°C for yeast or 37°C for bacteria. The MIC of a polyphenol was defined as the minimum concentration at which microbial

EGC: (−)-epigallocatechin; ECg: (−)-epicatechin gallate; EGCg: (−)-epigallocatechin-3-O-gallate. Minimum inhibitory concentration: μg/ml.
growth was inhibited. Growth inhibition was confirmed at the end of the 48-h culture period. Two experiments were performed for each microbial species and the lower MIC value (indicating stronger activity) was selected as the representative value. The polyphenol with the lowest MIC value among the 12 tested was then used to determine the MIC values for different inoculum sizes.

Of all the polyphenols used in this study, seven showed MIC values of <3,200 μg/ml against *M. pachydermatis*. Of these, castalagin, a polyphenol derived mainly from *Castanea crenata* and *Quercus acutissima*, had the lowest MIC value, 100 μg/ml. When tested against *C. albicans*, only theaflavin (1,600 μg/ml) showed a real-number MIC value (Table 3). These results suggest that castalagin may be effective against skin diseases caused by infection with *M. pachydermatis*, even if used as a monotherapy. Our results also show that (−)-epigallocatechin-3-O-gallate had a MIC value (50 μg/ml) comparable to that of castalagin against *S. intermedius*. All polyphenols had MIC values between 100 and 3,200 μg/ml against this bacterium except for (+)catechin and rutin, whose MIC values were >3,200 μg/ml. Castalagin had a low MIC value of 50 μg/ml against *A. xylosoxidans*, a non-glucose fermenting gram-negative bacterium. Except (+)catechin and rutin, the other polyphenols had values between 100 and 3,200 μg/ml against *A. xylosoxidans* and *S. intermedius* (Table 4). This suggests a wide antimicrobial activity spectrum of polyphenols against bacteria. The MIC values of castalagin against yeast and bacterial species of different inoculum sizes are shown in Table 5. The MIC value was 200 μg/ml against $1 \times 10^4$ CFU/ml of *M. pachydermatis* and 50 μg/ml against $8.8 \times 10^3$ CFU/ml of *S. intermedius* (Table 5). These results suggest that 200 μg/ml of castalagin may be effective against different types of pathogens.

This study had some limitations. One of these was that the only type of bacteria tested among the SIG was *S. intermedius*. Therefore, it will be necessary to determine the MIC values of the tested polyphenols against *S. delphini* and *S. pseudintermedius*. Also, the method of testing used for the yeast species in this study has not yet been formally accepted. Furthermore, while the aim of this study was to assess *Malassezia* spp., only one strain of one species of this pathogen was actually tested. Therefore, further investigations will need to be conducted using more strains.

In conclusion, among the 12 polyphenols tested in this study, castalagin appeared to exert the highest antimicrobial activity, suggesting it could be used in the treatment of canine chronic skin diseases associated with infections with *M. pachydermatis* and SIG. The potential use of castalagin for these purpose should be investigated further.

### Conflict of interest

None of the authors has any conflict of interest to declare.

### Acknowledgment

We would like to express our deepest gratitude to Prof. Takashi Tanaka of the Nagasaki University Graduate School of Biomedical Sciences for his kind provision of the polyphenols used in this study.
