doi: 10.3389/fgene.2012.00236

**ABCB1** gene encodes P-glycoprotein, an ATP-dependent drug efflux pump, which is responsible for drug transport across extra- and intra-cellular membranes. The variability in the expression of **ABCB1** may contribute to variable plasma efavirenz concentration which results in variability in the levels of suppression of the human immunodeficiency syndrome virus (HIV). The aim of the study was to evaluate the role of polymorphisms in **ABCB1** gene on plasma efavirenz levels and treatment response in the form of change in viral load and CD-4 cell count in HIV/AIDS patients receiving efavirenz-containing highly active antiretroviral treatment regimens. Two hundred and eighty-two HIV-infected patients were recruited from Thembela Lethu Clinic in Johannesburg and plasma efavirenz drug concentration levels were measured using LC-MS/MS. SNaPshot was used to genotype five known **ABCB1** single nucleotide polymorphisms (SNPs). Genotype-phenotype correlations were computed. The **ABCB1** 4036A/G and 4036G/G genotypes were significantly associated with low plasma efavirenz concentrations (P = 0.0236), while the **ABCB1** 1236C/T and 1236T/T genotypes were associated with high efavirenz concentrations (P = 0.0282). A haplotype **ABCB1** T-G-T-A is reported that is associated with significantly increased plasma efavirenz levels. This is the first report on 61A>G, 2677G>T/A, and 4036A>G SNPs in the South African population. **ABCB1** plays a role in determining the plasma concentrations of efavirenz and should be taken into account in future design of assays for genotype-based dosing of efavirenz-containing regimens.

**INTRODUCTION**

Efavirenz provides the backbone to first-line highly active antiretroviral treatment (HAART) in South Africa. HAART effectively prevents replication in the majority of patients (Mocroft et al., 2003). Thus, many HIV-infected patients are now living longer compared to the pre-HAART period. However, long term antiretroviral (ARV) treatment has its own challenges such as drug–drug interactions and the development of adverse drug reactions (ADRs). Drug–drug interactions are a major problem in HIV/AIDS patients due to co-morbidities such as TB and malaria.

FDA-approved ARV drugs, including efavirenz, indinavir, nelfinavir, and ritonavir are affected by the activities of the multidrug transporter P-glycoprotein (P-gp), coded by the **ABCB1** gene. **ABCB1** forms part of the ATP-binding cassette family with about 50 members and is located on chromosome 7q21.12, spanning 209.6 kb, and containing 29 exons (Bodor et al., 2005). Genetic variation in the **ABCB1** gene is known to alter mRNA stability or splicing activity (Fung and Gottesman, 2009). The three most common single nucleotide polymorphisms (SNPs) in the protein coding region of **ABCB1** are 1236C>T (rs1128503), 3435C>T (rs1045642), and 2677G>T/A (rs2032582), where multiple alleles have been reported. The 1236C>T SNP occurring in exon 13, does not result in an amino acid change, but may affect **ABCB1** expression through codon usage (Gu et al., 2004). The allele frequency of 1236T variant ranges from 10% among South Africans (Dandara et al., 2011) to 90% among Asians (Ambukkar et al., 1999). The 2677G>T/A SNP results in a change from serine to alanine or threonine at residue 893, but the effect of the changes on protein function is uncertain. The 3435T allele has been associated with reduced expression of P-gp, although it is synonymous (Meissner et al., 2004). Large inter-ethnic variability has been reported for the 3435C>T SNP with the **ABCB1** 3435C variant being the most frequent at 83, 58, 57, and 11% among Africans (Kenyans and Ghanaians), Asians (Chinese), Caucasians, and Yoruba individuals, respectively (Ameyaw et al., 2001). The **ABCB1** 3435T variant has been linked with good immune recovery in HIV/AIDS individuals, while the presence of the **ABCB1** 2677T variant has been strongly associated with virological failure (Motsinger et al., 2006). A few studies have suggested associations between **ABCB1** gene polymorphisms and variability in plasma efavirenz concentrations (Fellay et al., 2002; Mukonzo et al., 2009), but all the studies lack adequate sample size. There are conflicting reports on the effects of these SNPs on efavirenz treatment response (Cascorbi et al., 2001; Fellay et al., 2002; Cascorbi, 2006). Replication studies are thus necessary to understand the contribution of **ABCB1** gene variants to plasma efavirenz levels. Dandara et al. (2011) showed that genetic variants in **ABCB1** are frequent in the South African population, and this study is a continuation further evaluating the clinical significance of these SNPs. Therefore,
the aim of this study was to investigate the role of genetic polymorphisms in ABCB1 on plasma efavirenz levels in HIV/AIDS patients in the South African population.

RESULTS

The mean age of the HIV/AIDS patients was 41.3 years, and more than 75% (n = 227) were female. Of the patients, 7% and 10% smoked and consumed alcohol. The clinical characteristic of the patients included viral load and CD-4 cell count (Table 1).

COMPARISON OF ALLELE FREQUENCIES AMONG WORLD POPULATIONS

The genotypes for all the SNPs were observed in the HIV/AIDS patients, except the ABCB1 61G/G (rs9282564) genotype. All ABCB1 SNPs were in Hardy–Weinberg Equilibrium (HWE). The ABCB1 61A/G (rs9282564), 3435T/T (rs1045642), 4036G/G (rs3842), 1236T/T (rs1128503), 2677T/A, and 2677G/A (rs2032582) genotypes were present at frequencies of 0.006, 0.024, 0.036, 0.015, 0.004, and 0.004, respectively, among the South Africans. No individuals with an ABCB1 3435A/T allele was observed in the South African cohort (Table 2), and this is similar to what was reported by Dandara et al. (2011). The allele frequencies of SNPs in the South Africans were compared to the allele frequencies reported previously in other populations (Table 2), available from previous studies or the HapMap project (http://hapmap.ncbi.nlm.nih.gov/).

CORRELATION OF GENETIC VARIATION WITH PLASMA EFAVIRENZ CONCENTRATION

The ABCB1 4036A/G and 4036G/G genotypes were associated with significantly decreased efavirenz levels (P = 0.0236), compared to the 4036A/A genotype (Figure 1A). Fewer individuals with the ABCB1 4036G/G genotype changed treatment compared to the individuals with the 4036A/A genotype (Table 3). The ABCB1 1236C/T and 1236T/T genotypes were associated with significantly higher plasma efavirenz concentrations, compared to the 1236C/C genotype (P = 0.0282; Figure 1C). Compared to the ABCB1 1236C/C genotype, more individuals with the 1236T/T genotype changed antiretroviral regimens 1 year post treatment initiation (Table 3). No difference was observed when comparing individuals with efavirenz concentration above 4 μg/mL to those with concentrations below 4 μg/mL, with respect to change in treatment regimens (P = 0.571). No significant differences were observed in efavirenz concentrations between the ABCB1 2677G>T/A and ABCB1 3435C>T genotypes (Figures 1B,D).

HAPLOTYPE ANALYSIS

Haplotypes at the ABCB1 1236 and 2677 loci in all patients are presented in supplementary Table A1. The haplotypes with respect to 1236C>T, 2677G>T/A, 3435C>T, and 4036A>G SNPs C-G-C-A, C-G-C-G, C-G-T-G, T-G-C-A, T-G-T-A, T-G-T-G, T-T-T-G, and T-T-T-A had the highest mean plasma efavirenz concentrations (0.90 ± SD (μg/mL)) compared to 0.49 and 0.65 μg/mL among patients with the T-G-C-A or T-G-T-G haplotypes, respectively (Figure 2). The efavirenz concentrations differed significantly between individuals with the ABCB1 C-G-C-G and T-G-T-A haplotypes (P = 0.007) and were still significant after Bonferroni’s correction for multiple testing (cut-off significant P < 0.01).

UNIVARIATE AND MULTIVARIATE REGRESSION ANALYSIS OF EFAVIRENZ CONCENTRATION

Univariate regression analysis was performed to determine the effect of age, gender, tobacco smoking, alcohol use, BMI at baseline, CD-4 cell count, log10 HIV-RNA levels, ABCB1 haplotypes, ABCB1 1236C>T, 4036A>G, 3435C>T, and 2677G>T/A genotypes on plasma efavirenz concentrations (Table 4). The genotypes of the four SNPs 1236C>T, 2677G>T/A, 3435C>T, and 4036A>G significantly predicted efavirenz concentration individually and were, thus, included in the multivariate analysis together with age, gender, tobacco smoking, alcohol use and BMI at baseline. Stepwise backward regression analysis was then performed to identify the minimum set of independent variables that are predictive of plasma efavirenz levels and to determine the relative contribution of each variable to efavirenz concentration variability. Only three independent variables remained in the final model with P < 0.05, including ABCB1 1236C>T (standardized regression coefficient = 0.24; P = 0.004), ABCB1 4036A>G (standardized regression coefficient = 0.17; P = 0.009), and ABCB1 2677G>T/A (standardized regression coefficient = 0.36; P = 0.047). The adjusted coefficient of determination (R2) for the regression was 0.16, indicating that 16% of the total variance in efavirenz concentrations was explained by the model. ABCB1 1236C>T, 4036A>G, and 2677G>T/A genotypes accounted for 29, 23, and 17% (respectively) of the total variance in plasma efavirenz concentrations. When repeating the multivariate analysis among female patients only, the adjusted coefficient of determination (R2) for the regression was 0.18, indicating that 18% of the total variance in efavirenz concentrations was explained by the model.

FIGURE 1 | (A–D) ABCB1 4036A/G and G/G genotypes (P = 0.0236) are associated with reduced efavirenz levels, while 1236C/T and T/T genotypes (P = 0.0282) are associated with increased efavirenz levels in South African HIV/AIDS patients. Only significant P-values (without Bonferroni correction), using the dominant genetic model, are shown.

compared to the 16% explained when males and females were combined. However, the majority of HIV/AIDS patients in our study were female. Further statistical analysis comparing only the genetic- and non-genetic factors in the multivariate analysis, showed that the genetic factors alone explained 11% of variance in efavirenz levels, while the non-genetic factors only explained 3% compared to the 16% explained by the combined multivariate analysis.

*Only 282 patients had information on treatment regimens. ABCB1 61A>G was excluded based on being monomorphic.

DISCUSSION

HETEROGENEITY OF AFRICAN POPULATIONS IN TERMS OF GENETICS

To our knowledge, the present study is the first to report on the allele and genotype frequencies of the ABCB1 61A>G, 2677G>T/A, and 4036A>G polymorphisms in the South African population. However, the other SNPs have been previously reported by Dandara et al. (2011). This data contributes to the accumulation of information on genetic variants of pharmacogenetics relevance among Africans. The allele frequencies of the genetic polymorphisms in South Africans were also compared to the frequencies among other African, African-American, Asian, and Caucasian populations (Table 2). As expected there are significant differences in the allele frequencies between African populations and Caucasians, for example, the allele frequency of the ABCB1 3435T allele in African populations ranges from 0.07 to 0.12, but is present at a frequency of almost 0.6 in Caucasian individuals. Differences in allele frequencies between the African and Caucasian populations were also observed. The allele frequencies of the ABCB1 4036G, 2677T, and 2677A alleles were different to the frequencies reported in the Yoruba individuals (P < 0.0001). The differences in allele frequencies between the African and Caucasian individuals show that therapeutic drugs, including efavirenz, may not have...

*Only significant covariates in the multivariate regression analysis are shown.

We observed lower plasma efavirenz concentrations among individuals with the ABCB1 4036A/G and 4036G/G genotypes and this could perhaps be a result of the disruption of a miRNA binding site in the 3′UTR of ABCB1. Five poorly conserved miRNAs namely; miR-129, miR-491, miR-4795, miR-561, and miR-4717 have been predicted to target the 3′UTR region surrounding the ABCB1 4036A>G SNP using the TargetScanHuman 6.1 miRNA target prediction software. Disruption of these sites could potentially cause reduced transport of efavirenz by ABCB1 resulting in lower plasma efavirenz levels. In a different study among Ugandans, the ABCB1 4036A/G and 4036G/G genotypes were associated with higher efavirenz bioavailability (Mukonzo et al., 2009). In the current study, ABCB1 1236C/T and 1236T/T genotypes were associated with high plasma efavirenz concentrations, but there are conflicting reports on the effect of ABCB1 1236C>T genotypes in tacrolimus, cyclosporine, and sirolimus drug responses (Kuzuya et al., 2003; Anglicheau et al., 2004; Haufoir et al., 2004), making it difficult to draw conclusions. There are conflicting reports as well for the role or effects of ABCB1 2677G>T/A and 3435C>T polymorphisms (Schwab et al., 2003; Leschziner et al., 2007). Haas et al. (2005) reported an association between the ABCB1 3435T/T genotype and a decreased likelihood of virologic failure and decreased resistance to efavirenz, but not with plasma efavirenz exposure.

Clinical parameters such as CD-4 cell count, viral load, disease stage, hemoglobin, AST, and ALT levels were used as indicators of ARV treatment efficacy, underlying liver disease and disease progression in the HIV/AIDS patients. As expected, efavirenz-containing HAART led to a general (48%) increase in CD-4 cell count (cells/μL) and a 94% decrease in viral load (copies/mL) when baseline levels where compared to levels at 6 months post-initiation of treatment. Failure of reduction in viral load and emergence of opportunistic infections after 6 months led to ARV switching. Sustained viral load after 6 months and the presence of opportunistic infections are indications of possible treatment failure or non-adherence. On the other hand, other studies have shown that high plasma efavirenz concentrations are associated with development of adverse drug events leading to drug discontinuation (Marzolini et al., 2001; Lubomirov et al., 2011; Wyen et al., 2011).

**CONCLUSION**

The current study showed that the drug transporter ABCB1 contributes in predicting response to efavirenz treatment in the South African HIV/AIDS population. The ABCB1 4036A>G and 1236C>T polymorphisms were significantly correlated with low and high plasma efavirenz concentration levels, respectively. However, this data should be taken together with the variation in CYP2B6 which has a profound effect on efavirenz metabolism. The CYP2B6 516G>T SNP is known to be associated with high plasma efavirenz levels and the combined effect of CYP2B6 together with ABCB1 SNPs will be more informative in predicting response to efavirenz treatment. This strongly supports the development of a pharmacogenetic suite of gene variants to assist in deciding the HAART regimen for HIV/AIDS treatment in a clinical setting as well as the starting ARV dosage.

**MATERIALS AND METHODS**

**RESEARCH PARTICIPANTS**

All participants provided written informed consent and study approval was obtained from the University of Cape Town Health Science Faculty Research Ethics Committee, Cape Town, South Africa and the University of Witwatersrand Human Research Ethics Committee, Gauteng, South Africa. The research was performed in accordance with the guidelines of the Helsinki Declaration of 2008. Two hundred and eighty-two (n = 282) South African HIV/AIDS patients receiving efavirenz-based treatment for at least 6 months, were recruited to participate in this study. All subjects were of Bantu origin and comprised of Sotho/Tswana from Gauteng and Xhosa subjects from the Western Cape Province, South Africa. All subjects gave information on their ethnicity, age, health status (including self-reported adherence to treatment or pill counts), dietary, and smoking habits.
A 5 mL whole blood sample was obtained from each subject, and used for plasma sample collection as well as DNA extraction. DNA was isolated using a salting-out method adapted from Gustafson et al. (1987) or the GenElute™ Blood Genomic DNA Kit (Sigma-Aldrich, St. Louis, MO, USA). Steady-state plasma samples were available for 137 HIV/AIDS patients 12–16 h post dose with efavirenz. Plasma efavirenz concentrations were determined by LC/MS/MS (API 4000 triple quadrupole MS/MS Applied Biosystems, South Africa) according to the method by Chi et al. (2002). For the selection of SNPs and genotyping methods used, five previously reported SNPs in ABCK1 [GenBank accession: NM_000927.4], namely 61A>G, 1236C>T, 2677G>T/A, 3435C>T, and 4036A>G were selected for investigation based on having minor allele frequencies above 10% in the African-Americans, South African, or other African populations and were genotyped using SNaPshot mini-sequencing (Table 5).

Each PCR reaction contained, 50 ng of genomic DNA, 1X Green GoTaq Flexi Reaction Buffer (Promega Corporation, Madison, WI, USA), 0.2 mM of each of the deoxynucleotide triphosphates (dNTPs; Bioline, London, UK); 1.5 mM MgCl₂ (Promega Corporation, Madison, WI, USA); 40 pmol of the forward and reverse primers (Integrated DNA Technologies, Inc., Coralville, IA, USA); 1 U of GoTaq Flexi DNA Polymerase (Promega Corporation, Madison, WI, USA). The PCR reactions were carried out using a "MyCycler Thermal cycler" from Bio-Rad. PCR conditions were as follows: 3 min at 94°C; 40 cycles of 94°C for 30 s, the annealing temperature specific to each SNP for 30 s, 72°C for 50 s; and 10 min at 72°C for final extension.

Five microliters of each PCR product was pooled and 10 µL of the combined PCR products were cleaned using 1.5 U shrimp alkaline phosphatase (Fermentas Life Sciences, Burlington, Canada) and 2 U ExoI (Fermentas Life Sciences, Burlington, Canada) in a total reaction volume of 20 µL. The shrimp alkaline phosphatase and ExoI reaction was incubated at 37°C for 1 h and the enzymes were inactivated at 75°C for 15 min. SNaPshot single base extension of the genetic polymorphisms was performed on the “GeneAmp® PCR System 9700 version 3.08” (Applied Biosystems, Carlsbad, CA, USA) using the SNaPshot cycling programme as 96°C for 10 s, and then repeated for 25 cycles at 50°C for 5 s and 60°C for 30 s. The SNaPshot reaction (10 µL) contained 1 µL ABI Prism® SNaPshot™ Multiplex Kit (Applied Biosystems, CA, USA) and the pooled internal SNaPshot primers (Integrated DNA Technologies, Inc., Coralville, IA, USA). Following the SNaPshot reaction, the clean-up reaction was repeated using 1 U shrimp alkaline phosphatase using cycling conditions as mentioned before, and capillary electrophoresis was performed using a ABI 3130xl Genetic Analyzer (Applied Biosystems, Carlsbad, CA, USA). SNaPshot results were analyzed on the GeneMapper © Software version 4.1 (Applied Biosystems, Carlsbad, CA, USA).

**STATISTICAL ANALYSIS**

Statistical analysis was performed using the Graphpad Prism (Version 5, GraphPad Software Inc., San Diego, CA) and STATA (Version 11, StatSoft, USA) statistical programs. *ABCB1* haplotypes were inferred using Phase v2.1 (Stephens et al., 2001; Stephens and Donnelly, 2003; Stephens and Scheet, 2005). Pearson’s χ²-test and Fisher’s exact test were used to compare the allele frequencies to results previously published in populations of different ethnicity. Fisher’s exact test was also used to compare change in treatment regimen between the *ABCB1* genotypes. One-way analysis of variance, followed by Bonferroni’s multiple comparison tests, was used to determine the effect of *ABCB1* haplotypes on plasma log₁₀ efavirenz levels. Genotypes were dichotomized according to the dominant genetic model (wild-type = 0 and heterozygote/homozygote variants = 1). Univariate regression analysis was applied to log₁₀ efavirenz concentrations as dependent variable and the percentage change in efavirenz levels, with the 95% CI, was calculated as 100 × regression coefficient. Multivariate regression analysis was performed by including covariates from the univariate analysis, followed by stepwise backward removal. TargetScanHuman 6.1 miRNA target prediction software were used to predict miRNA binding to the *ABCB1* 3’UTR. The following equation was used to calculate the sample size required to achieve a 99% confidence-interval:

\[ N = \frac{[DEFF \times Np(1-\alpha)]/[(d2/Z\alpha/2 \times (N-1) + p \times (1-p))]}{\alpha} \]

DEFF is defined as the design effect, Z is the value for 99% confidence, \( \alpha \) is the frequency of the variant allele. A DEFF-value of 1 was used for random sampling, a Z-value of 1.96 and allele frequency of 0.1 was used to calculate the sample size of \( N = 239 \) samples. All statistical tests were performed two tailed, and statistical significance was defined as \( P < 0.05 \).

**AUTHORS’ CONTRIBUTIONS**

Marelize Swart carried out all of the molecular genetic studies and drafted the manuscript. Yuan Ren and Peter Smith both carried out the LC/MS/MS analysis of plasma efavirenz concentration. Collet Dandara conceived of the study, designed, coordinated the study, collected all the samples, assisted with statistical data analysis, helped to draft the manuscript and approved the final version. All authors read and approved the final manuscript.

**ACKNOWLEDGMENTS**

We thank Professor Patrick McPhail for facilitating sample collection from the Clinical HIV Research Unit at Thembu Lethu Clinic, Helen Joseph Hospital, Johannesburg, South Africa. Special thanks to the South African Medical Research Council (MRC), the National Research Foundation of South Africa (NRF), and the University of Cape Town for funding.
