Determinants of knowledge of critical danger signs, safe childbirth and immediate newborn care practices among auxiliary midwives: a cross sectional survey in Myanmar

Kyu Kyu Than,1,2 Alison Morgan,3 Minh Duc Pham,1,4 James G Beeson,1,2 Stanley Luchters1,4,5

ABSTRACT

Objectives  The re-emergence of community-based health workers such as the auxiliary midwives (AMWs) in Myanmar, who are local female volunteers, has been an important strategy to address global health workforce shortages. The Myanmar government recommends one AMW for every village. The aim of this study is to investigate the current knowledge of critical danger signs and practices for safe childbirth and immediate newborn care of AMWs to inform potential task shifting of additional healthcare responsibilities.

Methods  A cross-sectional survey was conducted from July 2015 to June 2016 in three hard-to-reach areas in Myanmar. Face-to-face interviews were conducted using a pretested questionnaire.

Results  Among 262 AMWs participating in the study, only 8% of AMWs were able to identify at least 80% of 20 critical danger signs. Factors associated with greater knowledge of critical danger signs included older age over 35 years (adjusted OR (AOR) 2.19, 95% CI 0.99 to 4.83), having received refresher training within the last year (AOR 2.20, 95% CI 1.21 to 4.01) and receiving adequate supervision (AOR 5.04, 95% CI 2.74 to 9.29). Those who employed all six safe childbirth and immediate newborn care practices were more likely to report greater knowledge of danger signs (AOR 2.81, 95% CI 1.50 to 5.26), adequate work supervision (AOR 3.18 95% CI 1.62 to 6.24) and less education (AOR 0.44, 95% CI 0.23 to 0.88).

Conclusion  The low level of knowledge of critical danger signs and reported practices for safe childbirth identified suggest that an evaluation of the current AMW training and supervision programme needs to be revisited to ensure that existing practices, including recognition of danger signs, meet quality care standards before new interventions are introduced or new responsibilities given to AMWs.

INTRODUCTION

The re-emergence of the role of community health workers (CHWs) in healthcare provision has been an asset to the global health workforce.1 Around the world, different types of CHWs have emerged that are adapted to the need of individual healthcare systems and country contexts.2 CHWs are defined as ‘community members who work almost exclusively in community settings and who serve as connectors between healthcare consumers and providers to promote health among groups that have traditionally lacked access to adequate care’.3 Most CHWs working in maternal and child health are women.

Auxiliary midwives (AMWs) are one of the largest voluntary health cadres in the country and have been trained by the government of Myanmar since 1978.4 They are local women with secondary level education who are willing to serve their own community with maternal and child healthcare service and who work without financial incentives. The aim of producing AMWs in the early years of the programme was twofold: to fill the gap in
the availability of skilled birth attendants (midwives) who were not accessible in remote rural villages of the country and to phase out traditional birth attendants as care providers. AMWs provide education and counselling to pregnant women on antenatal care, immunisation, nutrition, birth preparedness, breastfeeding, and postnatal care. They are also equipped with skills to conduct normal deliveries, identify pregnant women with greater risks of complication and facilitate early and timely referral.4,5

Myanmar has a critical shortage in human resources for health; there are only 14 health providers with midwifery skills (doctors, nurses, and midwives) per 10,000 persons. This is significantly less than 23 per 10,000 persons recommended by the WHO to achieve the 80% skilled coverage for maternal and child health.6 Although the Myanmar government recognises the need to increase the number of skilled birth attendants and the distribution of midwives, health system resources are lacking and policies to fill and sustain the human resource gap are not currently in place.7 Task shifting is one possible option to address human resource shortages, and the Ministry of Health has revitalised the AMW programme to help extend services to ‘hard-to-reach’ areas.8 The national target set by the Ministry is to have at least one trained AMW in every village by 2016.9 The Ministry also recommends task shifting evidence-based essential interventions to AMWs to improve the health of mothers and the newborns.9

Currently, AMWs’ training lasts for 6 months, including 3 months of theoretical learning and 3 months of practical skills provided by township health departments. The trainings are conducted under the guidance of the Ministry of Health.7 Within the current ‘Three Millennium Development Goals Fund’ (3MDG) for Magwe region, new and refresher trainings have been undertaken in Gangaw, Ngape and Seitphyu townships. Refresher trainings are provided by the township-level team, which consists of the township medical officer, township health nurse and other health staff within each township and entails 3–5 days covering the critical topics relevant to AMW practice. AMWs are supervised by the midwives in their township.10 Typically, a midwife is responsible for overseeing four to six AMWs and would visit each AMW every month to monitor performance. In practice, it is reported that many midwives are not able to regularly follow-up the AMWs for whom they are responsible.11

Although the number of AMWs has increased, there are few studies on AMW service provision and performance in Myanmar. Two studies conducted by the Department of Health in 2005 and 2011 reported that knowledge was low and that AMW skills were below satisfactory level. The first study included 211 AMWs from 12 townships and the second study included 287 AMWs from four townships.12,13 These studies assessed AMWs’ general maternal and child health knowledge and skills but did not focus on the critical danger signs.

Our study aimed to investigate the level of knowledge and practices specific to life-saving care for pregnant women and their newborns: recognition of critical danger signs during pregnancy and labour, clean and safe childbirth practices and immediate newborn care practices. In addition, we examined the determinants of knowledge level to inform future interventions needed to improve the care given by AMWs in Myanmar.

**METHODS**

**Study setting**

Myanmar is a country with geographically, culturally and socially diverse communities. Magwe region in central Myanmar and with a population of 3.9 million was purposively selected based on its high reported maternal mortality ratio (344 per 100,000 live births) and infant mortality rate (84 per 1000 live births).14,15 The region contains various hard-to-reach populations and in rural remote areas most of the birth takes place at home (nationally reported to be 72%).16 Within each township, villages were identified as hard-to-reach and non-hard-to-reach according to the 3MDG fund criteria (a score of 0–12 is accorded based on travelling time to the nearest facility, mode of travel, transport charges and roads affected by seasonal variation).17 Three townships in Magwe region (Gangaw, Ngape and Seitphyu) were purposively selected to represent the geographical diversity of the region and because they have high maternal and infant mortality.

**Study design and participants**

A cross-sectional survey using interviewer administered pretested questionnaire was conducted between July 2015 and June 2016. A list of practising AMWs was obtained from the township health departments and checked through discussions with the township medical officer. All practising AMWs in the three townships were recruited for interviews. AMWs who were not in the township and those who could not come to the rural health centre (RHC) due to bad weather or having a very young child at the time of the survey were not able to participate. A total of 262 AMWs participated in the study out of 308 invited to participate (85%).

**Data collection methods**

Data were collected using a pretested semistructured questionnaire in Myanmar language. Five trained interviewers conducted face-to-face interviews with AMWs after obtaining written, informed consent. Interviewers were not employed by or associated with the health system. Completing the questionnaire took approximately 30–45 min per interview. The questionnaire consisted of five main sections including socioeconomic and demographic characteristics, training and supervision of maternal and child health services, knowledge of risk and danger signs, practice of antenatal, birth, postnatal and newborn care and barriers and facilitators for provision of services. In order to reduce the recall bias, all the knowledge and practice questions were based on 6 months period before the data collection. Interviews were conducted in the closest Maternal and Child Health
Centre or RHC to each AMWs’ place of residence. All the participants were reimbursed with the actual cost of travel to the place of interview plus a daily allowance to cover meal costs (3000 kyats, equivalent to US$2.5).

**Data management and analysis**

Data were coded on the day of the interview by a different member of the research team to check for completeness and inconsistency. There were no missing data. Coded data were double entered into the software EpiData V.3.1 by two research assistants separately. Double data entry was then checked for consistency by the principal investigator and any discrepancies addressed through discussion with the research team. The principal investigator analysed the data using STATA V.13.1.

Binary and categorical variables were summarised by proportions and tabulations. Continuous variables were summarised using mean, SD and range. Differences between groups were assessed using a χ² test or univariable logistic regression with 95% CI. The effect of each of the independent variables was adjusted for all other independent variables in a multivariable logistic regression model. Variables were included in the model if they were known, or hypothesised, determinants of our outcomes of interest.

**Study measures**

Responses to the question ‘when was the last refresher training received’ was coded as ‘less than a year’ if the participant indicated training had been received more recently than 2014 and as ‘no training or more than 1 year’ if refresher training had not been received or received prior to 2014. The number of supervision visits in the last 6 months and the question on satisfaction of supervision were taken to create the adequate supervision variable as reported by AMWs in the study. The question on ‘how many times were you supervised in the last 6 months’ was categorised as ‘less than six times or no supervision received’ and ‘six times and more’. Another question explored their satisfaction with the received supervision and was asked as: ‘Are you satisfied with your supervision?’ Responses were re-categorised into a binary variable as ‘satisfied’ for responses ‘very satisfied’, ‘satisfied’ and ‘just satisfied’ and into ‘not satisfied’ when responses included ‘not very satisfied’ and ‘not satisfied at all’. A composite variable was constructed to describe the adequacy of supervision. If the number of supervision visits was six times and more in the last 6 months and the satisfaction question was categorised as satisfied, it was considered as ‘adequate supervision’ and if either the number of supervision was no or less than six times or the satisfaction question was categorised as not satisfied than it was considered as ‘not adequate’.

According to the latest AMW manual published in 2015, there are 20 critical danger signs: six in pregnancy, eight in childbirth and postpartum and six related to newborn care. Knowing critical danger signs is important to enable AMWs to refer mothers and newborns for timely and effective management of complications. Participants were coded as ‘high knowledge’ if they reported at least three pregnancy critical danger signs (out of six), four childbirth and postpartum critical danger signs (out of eight) and three newborn critical danger signs (out of six). All others participants were coded as ‘low knowledge’.

A safe childbirth practice variable was constructed using responses to questions on usage of a clean birth kit and postpartum haemorrhage prevention practices. The question ‘Do you normally use a clean birth kit’ was coded as ‘1’ for yes and ‘0’ for no. Frequency of Active Management of Third Stage of Labour (AMTSL) practices were coded into a binary variable grouping those who responded ‘always’, ‘mostly’ or ‘about half the time’ as ‘1’ and those who responded ‘sometimes’ or ‘rarely’ as ‘0’. A composite ‘safe childbirth practice’ score was then constructed by adding the value of these two variables (using a clean birth kit and practising AMTSL). A score of ‘2’ was considered ‘safe childbirth practice’ and scores of ‘0’ or ‘1’ was considered ‘not safe childbirth practice’.

AMWs were also asked about the use of misoprostol, an intervention introduced to AMW practice in the study townships in 2015 by the Ministry of Health.

Four immediate newborn care practice questions were given a score of 1 for ‘yes’ responses and 0 for ‘no’ responses. Practices assessed were wrapping the baby for warmth, immediate breast feeding after birth, clean cord care and wiping the newborns nose and mouth with a clean cloth or gauze. AMWs who reported all four immediate newborn care practices were categorised as providing ‘satisfactory newborn practices’, while all others were categorised as ‘not satisfactory’. AMWs were also asked about the use of misoprostol, an intervention introduced to AMW practice in the study townships in 2015 by the Ministry of Health.

Ethical considerations

Ethical approval for the study was obtained from the Ethics Review Committee of Department of Medical Research, Ministry of Health Myanmar (approval number 42A/ethics/DMR/2015). Ethical approval was also obtained from The Alfred Hospital Human Research Ethics Committee in Australia (approval number Project 150/15). Written information was provided in Burmese and written inform consent was obtained. Consent forms were stored in a secure location. All activities and procedures including those for data collection, data storage and data analysis were performed in accordance with the guidelines and regulations as stated in the study protocol.

**RESULTS**

**Characteristics of participants**

A total of 214 AMWs from the non-hard-to-reach villages and 48 AMWs from hard-to-reach villages participated in the survey (table 1). The majority (82%) of AMWs lived in the villages where they were born (native village) and
49% had worked as AMWs for 10 years or more. The mean age of AMWs was 32 years, and 42% had secondary and below education and 16% had university level of education. Forty-five per cent of AMWs in the study worked in other jobs in addition to being an AMW.

**Supervision and training**

All AMWs in the study were trained for 6 months within their respective townships. More than half (57%) had been trained before 2010 and 64% of the AMWs reported receiving some refresher training (table 2). Among those who had received refresher training, 80% received the refresher training only in 2015. Seventy per cent reported receiving supervision from a midwife six or more times within the last 6 months and 60% of these AMWs reported that this supervision was satisfactory.

**Knowledge of critical danger signs**

Nearly all AMWs (91%) knew the recommendation of four antenatal visits with a skilled attendant during pregnancy and 96% knew the recommendation of three postnatal visits within 14 days of birth. Regarding critical danger signs, AMWs were more knowledgeable about newborn (77%) compared with antenatal (58%) and birth and postnatal critical danger signs (54%) (table 3). During the antenatal period, vaginal bleeding, convulsions/fits and severe headache with blurred vision were the most frequently reported critical danger signs. During childbirth and postpartum, the most commonly reported danger signs were bleeding, placenta not expelled 1 hour after birth of the baby and convulsions/fits. Severe abdominal pain, fast and difficult breathing, fever and too weak to get out of bed were the least reported. Although knowing all 20 critical danger signs is an expected AMW competency, only 8% of participants knew 80% or more of these danger signs and only 34% of participants knew at least half of the critical danger signs in each category.

**Table 2** Training and supervision received by participating auxiliary midwives (AMWs)

| Variables                              | n (n=262) | Per cent |
|----------------------------------------|-----------|----------|
| **Year of first AMW training received**|           |          |
| 1978–1999                              | 75        | 28.6     |
| 2000–2009                              | 75        | 28.6     |
| 2010–2015                              | 112       | 42.8     |
| **Ever received refresher training**   |           |          |
| Yes                                    | 169       | 64.5     |
| No                                     | 93        | 35.5     |
| **Refresher training within 1 year**   |           |          |
| No refresher training                  | 93        | 35.5     |
| One year and more                      | 32        | 12.2     |
| Less than 1 year                       | 137       | 52.3     |
| **Number of supervision received within 6 months**| | |
| Less than six times                    | 77        | 29.4     |
| Six times and more                     | 185       | 70.6     |
| **Reported satisfaction of supervision**|          |          |
| Not satisfied                          | 74        | 28.2     |
| Satisfied                              | 188       | 71.8     |
| **Adequate supervision**               |           |          |
| Not adequate                           | 124       | 47.3     |
| Adequate                               | 138       | 52.7     |

---

*Adequate supervision was defined as receiving supervision six times or more within the last 6 months and was satisfied with the supervision received.*
Table 3  Knowledge of critical danger signs* for pregnancy, birth, postpartum and newborn care among participating auxiliary midwives (AMWs)

| Knowledge of critical danger signs                                      | n (n=262) | Per cent |
|-------------------------------------------------------------------------|-----------|----------|
| **Pregnancy (six items)**                                               |           |          |
| Vaginal bleeding                                                        | 214       | 81.6     |
| Convulsion/fits                                                         | 152       | 58.0     |
| Severe headache with blurred vision                                     | 152       | 58.0     |
| Fever and too weak to get out of bed                                    | 134       | 51.2     |
| Severe abdominal pain                                                   | 62        | 23.7     |
| Fast and difficult breathing                                            | 63        | 24.1     |
| Knowing three or more critical danger signs during pregnancy            | 151       | 57.6     |
| **Childbirth and postpartum (eight items)**                            |           |          |
| Not in labour within 6 hours of water breaking                          | 141       | 53.8     |
| Labour pain (contractions) continue for more than 12 hours              | 105       | 40.1     |
| Heavy bleeding after childbirth (pad/cloth soaked in less than 5 min)   | 116       | 44.3     |
| Bleeding increases                                                      | 189       | 72.1     |
| Placenta not expelled 1 hour after the birth of the baby (retained placenta) | 152     | 58.0     |
| Convulsion/fits                                                         | 156       | 59.5     |
| Fast and difficulty breathing                                           | 51        | 19.5     |
| Fever and too weak to get out of bed                                    | 52        | 19.9     |
| Knowing four or more critical danger signs during birth and postpartum  | 142       | 54.2     |
| **Newborn (six items)**                                                 |           |          |

*As defined in the 2015 Myanmar AMW manual.

Safe childbirth and immediate newborn care practices

The main tasks of AMWs are to perform normal deliveries and to identify and refer high-risk pregnancies and women and newborn showing danger signs to the nearest health facility. On average, AMWs in this study provided antenatal services to four pregnant women, childbirth services to two women and postnatal services to four women in the past 6 months. Although labour monitoring using partograph was included in the AMW manual and is widely recommended as an important tool for the management of labour, only one respondent answered ‘yes’ to ever using a partograph. In this study, 84% of AMWs reported normally using a clean birth kit (table 4). Eighty two per cent of AMWs self-reported of conducting AMTSL. However, only 41% of AMWs reported providing misoprostol after birth to prevent postpartum haemorrhage. Among those who used misoprostol, 75% used two tablets and 25% used only one tablet (compared with the recommended three tablet dosage). Only 31% of AMWs followed all four immediate newborn care practices for a normal birth. All six practices of safe childbirth and immediate newborn care were conducted by only 74 (28%) of AMWs in the study (table 4).

Determinants of high knowledge of critical danger signs

Using multiple logistic regression analysis and after adjusting for confounders, variables that were strongly associated with high knowledge of critical danger signs were age 35 years and over, receiving refresher training within 1 year and adequate supervision. AMWs that are older (35 years and over) were 2.19 times more likely to have higher knowledge of critical danger signs compared with AMWs aged less than 35 years (p=0.054). AMWs who had received refresher training within 1 year were 2.19 times more likely to have higher knowledge of the critical danger signs than those who...
Proportion of auxiliary midwives (AMWs) reporting specified childbirth and newborn care practices

| Reported practices | n   | Percentage |
|--------------------|-----|------------|
| **Childbirth practices (two items)** |     |            |
| Use a clean birth kit | 219 | 83.6       |
| Perform Active Management of Third Stage of Labour | 216 | 82.4       |
| Performing both practices for clean and safe childbirth | 209 | 79.8       |
| **Immediate newborn care practices (four items)** |     |            |
| Warming (wrapping the baby to keep warm) | 222 | 84.7       |
| Breast feeding at once (immediately) | 181 | 69.1       |
| Clean cord care | 152 | 58.0       |
| Wipe nose, mouth of newborn with clean cloth or gauze | 191 | 72.8       |
| Performing all the immediate newborn care practices | 81 | 30.9       |
| AMWs who reported practising six safe and clean childbirth and immediate newborn care practices | 74 | 28.2       |

Determinants of safe childbirth and immediate newborn care practices

Multiple logistic regression reveals that having high knowledge of critical danger signs and reported adequate supervision were positively associated with practicing clean and safe childbirth and immediate newborn care (table 6). AMWs with high knowledge of the critical danger signs were 2.81 times more likely to practice clean childbirth and immediate newborn care compared with those who had low knowledge (p=0.001). AMWs who reported that they had adequate supervision were 3.18 times more likely to practice safe childbirth and immediate newborn care compared with those who reported that they had no adequate supervision (p=0.001). AMWs with above secondary level of education were less likely to report safe childbirth and immediate newborn care practices than those with lower education levels. This could be due to the fact that AMWs with better education are more likely to be involved in other jobs with better financial incentives compared with those AMWs who are less educated. Similar findings have been reported by a previous study on AMW performance in Myanmar, which showed that high education level was negatively associated with good performance. Training is a major determinant of knowledge and practice by community health workers globally. In the present study, receiving refresher training within 1 year was strongly associated with knowledge of critical danger signs. As some of the AMWs in the study area and the immediate newborn care period. Recognising critical danger signs is an essential prerequisite to timely referral of women and newborns to life-saving interventions. Our study revealed low knowledge of critical danger signs among AMWs in the study area. This finding is consistent with the findings of a previous study of AMWs’ general knowledge including danger signs in four townships of Kyaukse, Myanmar and is concerning.

In the present study, AMWs with higher age (≥35 years) were more than twice as likely to be knowledgeable about critical danger signs compared with the younger age group. However, age was not associated with practice of care. A similar study of female community health workers in rural Nepal also found that women who were older had better knowledge of maternal and child health services. Our findings suggest that knowledge comes with experience and that the training needs to be strengthened to ensure that those newly engaged in the AMW work are appropriately knowledgeable.

Level of formal education was not associated with AMW knowledge in our study, but was inversely associated with provision of practice of care. We found that AMWs with higher than secondary level of education were less likely to report safe childbirth and immediate newborn care practices than those with lower education levels. This could be due to the fact that AMWs with better education are more likely to be involved in other jobs with better financial incentives compared with those AMWs who are less educated. Similar findings have been reported by a previous study on AMW performance in Myanmar, which showed that high education level was negatively associated with good performance. Training is a major determinant of knowledge and practice by community health workers globally. In the present study, receiving refresher training within 1 year was strongly associated with knowledge of critical danger signs. As some of the AMWs in the study conduct deliveries rarely, and to maintain good knowledge refresher trainings are important. The apparent success of more recent training (which was based on the new AMW manual) suggests that refresher trainings need to be extended to all AMWs. However, the overall low level of knowledge, even among recently trained AMWs calls for improved AMW training and support relating to the identification of danger signs. In the current AMW manual, extensive information covering a wide range of health topics may result in insufficient emphasis being
Table 5  Determinants of consistent high knowledge of critical danger signs among 262 enrolled auxiliary midwives (AMWs)

| Adequate                         | 67/138 (48.6)                                                            | 4.38 (2.39 to 7.99) | 5.04 (2.74 to 9.29) |         |

Bold indicates statistical significance.

placed on the more important topics, such as danger signs. Information such as using a partograph to assess the progress of labour is included, despite only 1 out of 262 participants in our study reporting having ever used a partograph. In terms of the training, the right content and appropriate methodology that suits the trainees is an important factor to be taken into consideration. Therefore, curriculum for training AMWs needs to be revisited and revised to prioritise the most relevant and practical information needed by AMWs.

Supervision is recognised internationally and in Myanmar as important for maintaining or increasing the community health workers’ performance and quality of care. Previous studies illustrate that both the frequency of visits and the satisfaction of supervisee are important elements of effective supervision. Our study findings show that supervision is a consistent determinant of both knowledge and practice. AMWs who reported adequate supervision were five times more likely to have higher knowledge on critical danger signs and three times more likely to provide safe childbirth and immediate newborn care practices. To accelerate effective supervision, mechanisms for frequent, quality supervision need to be incorporated into AMW training packages. Although many studies note that supervision is essential, AMWs supervision in Myanmar is low.

A systematic review done by Hill et al in 2014 found that supportive supervision given by formal health workers motivates community health workers, while also building trust and confidence between the two workers. Similar opportunities to build trust and confidence exist in Myanmar as supervision of AMWs is largely conducted by midwives in the local rural health centre. Although our study was limited to supervision by the immediate supervising midwife, supervision by other level of healthcare workers and community members has been effective in other settings and should be explored in the Myanmar context.

The 2006 Lancet series on maternal survival emphasised that the effectiveness of lay health workers programmes depend on comprehensive training, considerable supervision and logistical input, along with good planning. It is also well evident that community level health worker programmes are not stand-alone initiatives, and all effort within the health system must be involved to strengthen the knowledge and skills of AMWs who are the frontline workers of the hard-to-reach rural areas with innovative and effective training and supervision packages.

There are a number of limitations to the present study. Practices of AMWs were based on self-reported practices rather than actual observed performance, and over-reporting can be a problem with this approach. Our finding of low knowledge and poor practices may therefore still be an underestimate of the size of the problem. As a cross-sectional study, the study is not able to determine cause–effect relationships. Creating composite variables for analysis may impose misclassification bias and findings should be interpreted with caution. Despite these limitations, results revealed that adequate supervision and regular refresher trainings are strongly correlated with AMW knowledge and practice relating to safe childbirth practices and knowledge. These findings suggest that greater investment in training and supervision is warranted.

Myanmar, a country in transition, with a fragile and weak health system, has chosen the path of training...
AMWs in response to national shortages in human resources for health. This policy is in line with WHO's task-shifting recommendations that advocate for training and supporting lay health workers to perform specified tasks often performed by higher-level health cadres in order to improve access to care for hard-to-reach communities. However, our study finds that AMWs currently report low levels of knowledge regarding critical danger signs and poor practices relating to safe childbirth and immediate newborn care. Our findings underscore the need for comprehensive, skill-based training module with close supervision and support mechanism in order to improve the knowledge and skills of AMWs in Myanmar before future task shifting.

Acknowledgements
The authors would like to acknowledge the Department of Public Health, Ministry of Health, Myanmar for the collaboration and all the administrative support given by the Magwe Regional Health Department and all the health staff in the three study townships. We are also grateful to Burnet Institute Myanmar research team members (Thazin La, Kyaw Soe Thant, Tin Tin Wai and Thandar Aye) for kindly assisting in data collection. We would also like to thank all the AMWs who participated in the study without whom this study would not have been possible.

Contributors
KKT contributed to the study design, data collection, data analysis and led the first draft and finalisation of the manuscript. AM contributed to data analysis and development of the manuscript. MDF contributed to data analysis. JGB contributed to the study design and development of the manuscript. SL contributed to the study design, data analysis and led the revisions of the manuscript. All authors read and approved the final manuscript.

Funding
The Burnet Institute is supported by funding from the Victorian Operational Infrastructure Support Program and National Health and Medical Research Council (NHMRC) Independent Research Institute Infrastructure Support Scheme. James G Beeson (JGB) and Stanley Luchters (SL) were supported by NHMRC fellowships. Kky Kky Than (KKT) was supported by an Australian Award Scholarship of the Australian Government. Minh Duc Pham (MDF) was supported by an International Postgraduate Research Scholarship (IPRS) from the Commonwealth of Australia and a Victorian International Research Scholarship (VIRS) from State Government of Victoria, Australia.

Competing interests
None declared.

Patient consent
Detail has been removed from this case description/these case descriptions to ensure anonymity. The editors and reviewers have seen the detailed information available and are satisfied that the information back up the case the authors are making.

Ethics approval
Ethical approval for the study was obtained from the Ethics Review Committee of Department of Medical Research, Ministry of Health Myanmar (approval number 42A/ethics/DMR/2015). Ethical approval was also obtained from The Alfred Hospital Human Research Ethics Committee in Australia (approval number Project 150/15). Written information was provided in Burmese and written informed consent was obtained.

Provenance and peer review
Not commissioned; externally peer reviewed.

Data sharing statement
Data will be available on request as this is part of a larger study on “The role of auxiliary midwives in community-based maternal and child health care in Myanmar: an assessment of the feasibility of task shifting”.
