Contrast-enhanced Ultrasound (CEUS) vs contrast-enhanced computed tomography for multilocular cystic renal neoplasm of low malignant potential

A retrospective analysis for diagnostic performance study

Kun Shan, MSa, A BU DU LI AI ZE ZI HA LI FU, BSb, Ningning Liu, MSb, Qiliang Cai, MDb, Qingfeng Fu, MSb, Leyi Liu, Msb, Xiaoyu Sun, BSb, Zhihong Zhang, MDb,∗

Abstract

Multilocular cystic renal neoplasm of low malignant potential (MCRNLMP) might be benefited from nephron-sparing surgery. Contrast-enhanced computed tomography is used for the diagnosis of MCRNLMP but contrast-enhanced ultrasound has lack of nephrotoxicity and several advantages over contrast-enhanced computed tomography and contrast-enhanced magnetic resonance. The purpose of the study was to compare diagnostic parameters of preoperative contrast-enhanced ultrasound against contrast-enhanced computed tomography for the detection of MCRNLMP in patients who faced curative surgery for complex cystic renal mass.

Data regarding contrast-enhanced ultrasound, contrast-enhanced computed tomography, and clinicopathological results of 219 patients who underwent curative surgery for complex cystic renal mass (Bosniak classification III or IV) were retrospectively collected and analyzed. Bosniak classification for imaging modality and the 2016 WHO criteria for clinic pathology were used for detection of MCRNLMP.

Contrast-enhanced ultrasound, contrast-enhanced computed tomography, and clinicopathology were detected 68, 66, and 67 as a MCRNLMP respectively. Contrast-enhanced ultrasound and contrast-enhanced computed tomography had 30.37% and 29.27% sensitivities for the detection of MCRNLMP. While 60% and 50% specificities respectively. Bosniak classification III (P = .045) and lower mean Hounsfield unit (P = .049) were associated with the prevalence of MCRNLMP. Contrast-enhanced computed tomography was detected 6 and 7, while contrast-enhanced ultrasound detected 3 and 2 complex cystic renal mass as false positive and false negative MCRNLMP respectively. A contrast-enhanced ultrasound had 0.011 to 1.0 diagnostic confidence and contrast-enhanced computed tomography had 0.045 to 0.983 diagnostic confidence for decision making of nephron-sparing surgeries.

Contrast-enhanced ultrasound may have better visualization of MCRNLMP than contrast-enhanced computed tomography.

Level of Evidence: III.

Abbreviations: ANOVA = analysis of variance, q = Critical value, HU = hounsfield unit, MCRNLMP = multilocular cystic renal neoplasm of low malignant potential, TNM = tumor, nodes, and metastases, WHO = World Health Organization.

Keywords: Bosniak classification, contrast-enhanced computed tomography, contrast-enhanced ultrasound, hounsfield unit, multilocular cystic renal neoplasm of low malignant potential, nephron-sparing surgery

1. Introduction

Multilocular cystic renal neoplasm of low malignant potential (MCRNLMP) are accounted for only 2% to 4% of clear renal cell carcinoma [1] with an excellent prognosis.[2] The 2016 World Health Organization (WHO) defined it as a renal tumor that is composed entirely of numerous cysts, the septa of which consist of small groups of clear cells without extensive growth, and are morphologically inseparable from low-grade clear renal cell carcinoma.[3] In MCRNLMP, patients cannot be affected by large tumor size or advanced stage. Therefore, patients of MCRNLMP might be benefited from nephron-sparing surgery.[4]

Imaging methods like magnetic resonance imaging and computed tomography are used frequently for the diagnosis of MCRNLMP.[5] Contrast-enhanced ultrasound is a new technique for the diagnosis of renal cell carcinoma.[6] Unlike magnetic resonance imaging and computed tomography, contrast-enhanced ultrasound provides real-time images, zero-radiation, and cost-effective[7] with high accuracy even at bedside.[8] Contrast-enhanced ultrasound has lack of nephrotoxicity and has several advantages over contrast-enhanced computed tomography and contrast-enhanced magnetic resonance.[9] The Bosniak classification system is preoperatively used for the differentiation of MCRNLMP from the other cystic renal cell carcinoma.[4] A new proposal for the Bosniak classification was not developed for contrast-enhanced ultrasound.[10] Contrast-enhanced ultrasound grading of Bosniak classification can appropriately change clinical management of renal masses by changing the probability of malignancy compared to Bosniak classification for contrast-enhanced computed tomography and contrast-enhanced magnetic resonance.[9]

The objectives of a non-randomized retrospective analysis of the cross-sectional study were to compare the diagnostic parameters of preoperative contrast-enhanced ultrasound against those of contrast-enhanced computed tomography for the detection of MCRNLMP in patients who faced curative surgery for renal cell carcinoma (Bosniak classification III or IV) considering the clinicopathological results as the reference standard. Also, to determine the preoperative factors differentiating MCRNLMP from the other cystic renal cell carcinoma.

2. Materials and methods

2.1. Ethics approval and consent to participant

The designed protocol of the study (Reg. No. ZXMFSY00060, dated May 7, 2020) was approved by the Second Hospital of Tianjin Medical University review board. All enrolled patients have signed prior informed consent before enrollment in the study regarding diagnosis, radiology, surgery, and pathology, and publication of anonymized information of patients in the article form. Written approval was taken before collection of data from competing authority.

2.2. Study population

From January 12, 2018 to April 15, 2020, a total of 5469 patients underwent curative surgery for renal cell carcinoma at the Second Hospital of Tianjin Medical University, Tianjin, Hebei, China. Of these, on contrast-enhanced ultrasound and contrast-enhanced computed tomography evaluation basis, 287 patients had complex cystic renal mass (Bosniak classification III (suspicious for malignancy) or IV (malignant)). Of 287 patients, 61 patients had not performed contrast-enhanced ultrasonographic images, 5 patients had von Hippel-Lindau disease, and 2 patients had dialysis-related renal cell carcinoma. Therefore, data of these patients were excluded from the analysis. Data regarding contrast-enhanced ultrasound, contrast-enhanced computed tomography, and the clinicopathological results of 219 patients (18≥ years) who underwent curative surgery for renal cell carcinoma, and had complex cystic renal mass (Bosniak classification III or IV) were retrospectively collected and analyzed (Fig. 1).

2.3. Contrast-enhanced ultrasound

Patients were injected with 1.2 ml bolus microbubble (SonoVue; Bracco Imaging France, Léonard de Vinci, Massy, France) by a 20-G intravenous cannula (BD Venflon, BD, Franklin Lakes, NJ, USA), followed by a 10-ml normal saline flush (Baxter Pharmaceuticals, Deerfield, IL, USA). Both kidneys were examined under LOGIQ E10 (GE Healthcare, Chicago, IL, USA). After injection of contrast agent cine loops were acquired under continuous scanning and images were stored. Lesions were evaluated qualitatively (Fig. 2). Image analyses were performed as per the Bosniak classification.[11] Contrast ultrasound was performed and analyzed by ultrasound technologists of the institute. All have minimum of 3-years of experience in renal images.

2.4. Contrast-enhanced computed tomography

Corticomedullary-phase, nephrographic phase, and excretory-phase contrast-enhanced computed tomographic images were performed using a 64-channel single-source, dual-energy helical computed tomography scanner (SOMATOM Definition Edge, Siemens Healthineers Malvern, PA, USA), acquiring 128 slices/rotation through the double sampling of the detector rows, 0.384 mm spatial resolution, 100kw generator power at 100kv, and 384 reconstructing slices after intravenous administration of 1 mm/ml Gadovist (Bayer, Reading, Berkshire, United Kingdom). The region of interest was drawn outside of cystic renal mass and mean Hounsfield unit (HU) of each region of interest was measured (Fig. 3). Image analyses were performed as per the Bosniak classification.[10] Contrast-enhanced computed tomography was performed and analyzed by radiologists of the institute. All have minimum of 3-years of experience.

2.5. Clinic pathology

Pathology of surgically removed cystic renal mass was performed by pathologists of the institute. All have minimum of 3-years of experience in genitourinary pathology. The 2016 WHO criteria used to define MCRNLMP.[15] Gross and microscopic features of cystic renal mass were defined as per Fuhrman nuclear grade (Fuhrman grades 1 and 2: low grade, Fuhrman grades 3 and 4: high grade) and TNM (tumor, nodes, and metastases) staging.[12]

2.6. Diagnostic parameters

The diagnostic criteria for MCRNLMP and another cystic renal cell carcinoma on contrast-enhanced ultrasound and contrast-enhanced computed tomography was just the existence of
enhancement. The enhancement was judged by visual inspection. The ratio of true positive MCRNLMP detected by imaging modality to total true characterization of complex cystic renal mass by that imaging modality was considered as sensitivity and the ratio of false-positive MCRNLMP detected by imaging modality to the total false characterization of complex cystic renal mass by that imaging modality was considered as specificity.

2.7. Beneficial score analysis
Beneficial score analysis for each imaging method was calculated as per Eq. (1) [13]:

\[
\text{Beneficial score} = \frac{\text{True positive MCRNLMP detected}}{\text{Data of cysts included in the analysis}} \times \left(1 - \frac{\text{False positive MCRNLMP detected}}{\text{Data of cysts included in the analysis}}\right)
\]

Level of diagnostic confidence above which decision of nephron-sparing surgery was made.

Figure 1. Flow diagram of retrospective analysis.
True positive MCRNLMP: Complex cystic renal mass was defined as a MCRNLMP by Bosniak classification\cite{10,11} and 2016 WHO criteria.\cite{3}

False-positive MCRNLMP: Complex cystic renal mass was defined as a MCRNLMP by Bosniak classification\cite{10,11} but failed in the definition of the 2016 WHO criteria.\cite{3}

2.8. Statistical analysis

SPSS V25.0 IBM Corporation, Chicago, IL, USA was used for statistical analysis purposes. Univariate following multivariate linear regression analysis was performed to determine the preoperative factors differentiating MCRNLMP from the other cystic renal cell carcinoma.\cite{4} One-way analysis of variance (ANOVA) or unpaired $t$-test was performed for continuous parameters. The Tukey test (considering critical value $(q) > 3.345$ as significant) was performed for post hoc analysis. The Fischer exact test or the Chi-Squared independence test was performed for constant parameters. All results considered significant if $P$ value was reported less than .05.

3. Results

3.1. Contrast-enhanced ultrasound

Contrast-enhanced ultrasound detected 68 cysts as a MCRNLMP and 151 cysts as the other cystic renal cell carcinoma. The results of contrast-enhanced ultrasound reported no difference for Bosniak classification ($P = .051$) and diameter ($P = .663$) between MCRNLMP and the other cystic renal cell carcinoma but MCRNLMP were more calcified ($P = .003$). The detailed contrast-enhanced ultrasonographic characteristics of complex renal cysts before curative surgery are reported in Table 1.

3.2. Contrast-enhanced computed tomography

Contrast-enhanced computed tomography was detected 66 cysts as a MCRNLMP and 153 cysts as the other cystic renal cell carcinoma. The results of contrast-enhanced computed tomography reported no difference for Bosniak classification ($P = .051$) and diameter ($P = .663$) between MCRNLMP and the other cystic renal cell carcinoma but MCRNLMP were more calcified ($P = .003$). The detailed contrast-enhanced ultrasonographic characteristics of complex renal cysts before curative surgery are reported in Table 2.

3.3. Clinic pathological characters

Clinic pathological study was characterized complex cystic renal mass as 64 benign cysts, 67 MCRNLMP, and 88 as the other cystic renal cell carcinoma. Age was higher in patients with
benign cyst. Hemorrhagic/necrotic nature of cysts was fewer reported in the MCRNLMP. The other clinic pathological characteristics are summarized in Table 3.

3.4. Diagnostic parameters

Contrast-enhanced computed tomography had significant numbers of false positive \((P = .039)\) and false negative \((P = .022)\) MCRNLMP detected as compared to clinic pathology results (Table 4).

Contrast-enhanced ultrasound and contrast-enhanced computed tomography had 30.37% and 29.27% sensitivities for the detection of MCRNLMP. While 60% and 50% accuracies respectively (Table 5).

3.5. Beneficial score analysis

A contrast-enhanced ultrasound had 0.011 to 1.0 diagnostic confidence and below 0.011 diagnostic confidence, it had a risk of overdiagnosis for detection of MCRNLMP. Contrast-enhanced computed tomography had 0.045 to 0.983 diagnostic confidence, below 0.045 it had the risk of over diagnosis, and above 0.983 it had the risk of under diagnosis for detection of MCRNLMP (Fig. 4).

3.6. MCRNLMP risk assessment

Univariate following multivariate analysis reported that Bosniak classification III (odd ratio 2.441; 95% confidence limit: 1.111–2.431; \(P = .045\)) and lower mean HU (odd ratio 1.345; 95% confidence limit: 1.012–1.41; \(P = .049\)) were associated with prevalence of a MCRNLMP.

4. Discussion

The study was reported \(1.23\% \) (67/5, 467) prevalence of MCRNLMP. The 2004 WHO criteria suggested the prevalence of a MCRNLMP in the range of \(1.0\% \) to \(1.5\%\).\[4\] The results of the current study were within the limit of the 2004 WHO criteria for complex cystic renal mass.

The study reported that contrast-enhanced ultrasound had the same sensitivity but high specificity than contrast-enhanced

### Table 1

| Characters | Multilocular cystic renal neoplasm of low malignant potential | The other cystic renal cell carcinoma | Comparisons between group |
|------------|-------------------------------------------------------------|-------------------------------------|---------------------------|
| Data of cysts included in the analysis | 66 | 151 | \(P\) value |
| Bosniak classification | 33 (49) | 51 (34) | .051 |
| IV | 35 (51) | 100 (66) | |
| Calcification | Yes | 20 (29) | 18 (12) | .003 |
| No | 48 (71) | 133 (88) | |
| Diameter (cm) | Minimum | 2.10 | 1.35 | .663 |
| Maximum | 10.10 | 9.89 | |
| Mean ± SD | 4.08 ± 1.24 | 4.17 ± 1.48 | |

*Significant difference.

Descriptive data are presented as number (frequency) and continuous data are presented as mean ± SD.

Fisher exact test for constant parameters and unpaired t-test for continuous parameters were used for statistical analysis.

A \(P < .05\) was considered significant.

\(HU = \) hounsfield unit.

Contrast-enhanced computed tomography was performed and analyzed by radiologists of the institute. All have minimum of 3-years of experience in renal images.

### Table 2

| Characters | Multilocular cystic renal neoplasm of low malignant potential | The other cystic renal cell carcinoma | Comparisons between group |
|------------|-------------------------------------------------------------|-------------------------------------|---------------------------|
| Data of cysts included in the analysis | 66 | 153 | \(P\) value |
| Bosniak classification | III | 39 (59) | 45 (29) | <.0001 |
| IV | 27 (41) | 108 (71) | |
| Calcification | Yes | 21 (32) | 17 (11) | .001 |
| No | 45 (68) | 136 (89) | |
| Diameter (cm) | Minimum | 2.11 | 1.33 | .851 |
| Maximum | 10.12 | 9.91 | |
| Mean ± SD | 4.11 ± 1.25 | 4.15 ± 1.52 | |
| Mean HU | During pre-contrast phase | 25.12 ± 6.15 | 27.81 ± 8.45 | .021 |
| During corticomedullary phase | 32.91 ± 7.16 | 48.18 ± 9.15 | <.0001 |
| During early excretory phase | 40.15 ± 6.45 | 52.11 ± 8.81 | <.0001 |

*Significant difference.

Descriptive data are presented as number (frequency) and continuous data are presented as mean ± SD.

Fisher exact test for constant parameters and unpaired t-test for continuous parameters were used for statistical analysis.

A \(P < .05\) was considered significant.

\(HU = \) hounsfield unit.

Contrast-enhanced computed tomography was performed and analyzed by ultrasound technologists of the institute. All have minimum of 3-years of experience in renal images.
## Table 3
Clinical conditions of patients who underwent curative surgery and pathological features of surgically removed complex cystic renal mass.

| Characters                          | Benign cyst | Multilocular cystic renal neoplasm of low malignant potential | The other cystic renal cell carcinoma | Comparisons between group | q-value |
|-------------------------------------|-------------|--------------------------------------------------------------|---------------------------------------|----------------------------|---------|

Multilocular cystic renal neoplasm of the low malignant potential detected by the 2016 WHO criteria.
Numerical data are demonstrated as frequency (percentage) and continuous data are demonstrated as mean±SD.
One-way ANOVA following Tukey post hoc test was used for statistical analysis.
N/A = not applicable.
A P<.05 and q>3.345 were considered significant.
Pathology of surgically removed cystic renal mass was performed by pathologists of the institute. All have minimum of 3-years of experience in genitourinary pathology.
Table 4
Results according to imaging methods and clinicopathology for complex cystic renal mass.

| Parameters | Clinicopathology | Contrast-enhanced ultrasonography | Contrast-enhanced computed tomography |
|------------|------------------|----------------------------------|---------------------------------------|
| Data of cysts included in analysis | 219 | 219 | 219 |
| True positive multicellular cystic renal neoplasm of low malignant potential detected | 67 (31) | 65 (30) | .917 | 60 (27) | .528 |
| True negative multicellular cystic renal neoplasm of low malignant potential detected | 152 (69) | 149 (68) | .837 | 145 (67) | .539 |
| False positive multicellular cystic renal neoplasm of low malignant potential detected | 0 (0) | 03 (1) | .247 | 06 (3) | .039 |
| False negative multicellular cystic renal neoplasm of low malignant potential detected | 0 (0) | 02 (1) | .479 | 07 (3) | .022 |

A Chi-Squared independence test was performed for statistical analysis.

1 With respect to clinicopathology.

A P< .05 was considered significant.

Significant difference with respect to clinicopathology.

Multicellular cystic renal neoplasm of low malignant potential by Boosniak classification for imaging modality and those were detected by the 2016 WHO criteria for clinicopathology.

Table 5
Diagnostic performance of imaging methods for multicellular cystic renal neoplasm of low malignant potential.

| Parameters | Contrast-enhanced ultrasonography | Contrast-enhanced computed tomography |
|------------|----------------------------------|---------------------------------------|
| Sensitivity | 30.37% | 29.27% |
| Specificity | 60.00% | 50.00% |
| Positive predictive value | 97.01% | 89.55% |
| Negative predictive value | 1.97% | 4.01% |
| Likelihood ratio | 75.93% | 58.04% |

computed tomography. For complex cystic renal mass contrast-enhanced, computed tomography is superior to contrast-enhanced ultrasound because contrast-enhanced ultrasound is defined as a type of kidney tumor only[14] but high sensitivity is required than high specificity in cases of a MCRNLMP for decision making of curative surgeries.[13] Contrast-enhanced ultrasound improved lesion detection rate and decreases the misdiagnosis rate for complex cystic renal mass.

Contrast-enhanced computed tomography had detected high false negative (7 vs 2) MCRNLMP than contrast-enhanced ultrasound. The computed tomography has difficulties in interpreting density values of complex cystic renal mass and sometimes it may detect convex protrusion as clear cell renal cell carcinoma,[14] detection of small cyst in the interpolar portion of the kidney is difficult (by both imaging methods), and computed tomography of obese patients are challenging,[16] leads to false-negative results. The study reported that contrast-enhanced computed tomography had detected high false positive (6 vs 3) MCRNLMP than contrast-enhanced ultrasound. In the current study, a benign cyst and the other cystic renal cell carcinoma mostly had hemorrhagic/necrotic cyst fluids nature (60%; 85 out of 152), which was detected as obtusely margined convex protrusion[4] by contrast-enhanced computed tomography leads to false-positive results. The results of the current study were agreed with the results of retrospective studies,[16,17] a prospective study,[14,18,19] and a diagnostic evaluation study of contrast-enhanced ultrasound against magnetic resonance imaging[20] for complex cystic renal masses. Contrast-enhanced ultrasound better visualized complex cystic renal mass than contrast-enhanced computed tomography.

Contrast-enhanced computed tomography had reported fewer numbers of MCRNLMP with Boosniak classification IV than contrast-enhanced ultrasound. The distribution of vascularization into intrahepatic septa and intracytic nodules plays an important role in the diagnosis of complex cystic renal mass by imaging modalities.[21] Ultrasound is very sensitive to blood flow to judge complex cystic renal mass. The effect of separating blood supply within the lesion is very good, so it is more accurate to judge the Boosniak classification of complex cystic renal mass.[15] Contrast-enhanced computed tomography often underestimates the Boosniak classification of complex cystic renal mass.

The study reported that Boosniak classification III and lower mean HU were associated with the prevalence of MCRNLMP. The results of the study were agreed with the study.[4] HU value is associated with the density of tumor and MCRNLMP has low tumor density.[4] Contrast-enhanced computed tomography may indirectly helpful for the detection of MCRNLMP from the other cystic renal cell carcinoma. A contrast-enhanced ultrasound had high diagnostic confidence for decision making of nephron-sparing surgeries than the contrast-enhanced computed tomography. The results of the study are agreed with the results of a retrospective study.[17] A prerequisite for reliable classification of renal lesions is the close collaboration of radiologists and urologists for their management.[22] An ideal treatment for MCRNLMP is nephron-sparing surgery while radical nephrectomy is preferred in case of the other cystic renal cell carcinoma for >5 cm diameter tumor.[23] If urologist makes the decision of radical nephrectomy then either of imaging modality will help for decision making of curative surgery but if urologist makes the decision of nephron-sparing surgery, in such condition contrast-enhanced ultrasound is required for decision making of nephron-sparing surgery to decrease the risk of another surgery (radical nephrectomy). Contrast-enhanced ultrasound is problem solving imaging method for curative surgeries of complex cystic renal mass.

There are several limitations of the study, for example, retrospective study and lack of control (enhanced nuclear magnetic resonance imaging) index test. Contrast-enhanced ultrasound is cost-effective than contrast-enhanced computed tomography[24] and magnetic resonance imaging[25] for the characterization of cystic renal lesions but the study did not evaluate cost parameters. The diagnostic accuracies did not compare for imaging modalities regarding the other cystic renal cell carcinoma. Large numbers of benign cyst detected in pathology after curative surgeries were misdiagnosed as the other cystic renal cell carcinoma by imaging modalities. Multilocular cystic nephroma showed enhanced hairline-thin and thick septa by imaging modalities that are responsible for misdiagnosis.[15] An interrater reliability among readers did not evaluated. Contrast-enhanced ultrasound had 30.37% sensitivity and 60%
accuracy for the detection of MCRNLMP, which are quite lower than the study would expect from other studies regarding cystic lesions.\(^{[17]}\) The reasons for such lower diagnostic parameters are that the detection of MCRNLMP was on the basis of complex cystic renal mass (absolute sensitivity and specificity). The differentiation between MCRNLMP and tubulocystic renal cell carcinoma might be difficult. The number of tubulocystic renal cell carcinoma did not report in the study.

5. Conclusions
Contrast-enhanced ultrasound may have the same sensitivity and high specificity as contrast-enhanced computed tomography for the detection of multilocular cystic renal neoplasm of low malignant potential. Contrast-enhanced ultrasound may be better visualized complex cystic renal mass than contrast-enhanced computed tomography. Contrast-enhanced computed tomography underestimates the Bosniak classification of complex cystic renal mass. Contrast-enhanced ultrasound is required for decision making of nephron-sparing surgery for complex cystic renal mass (Bosniak classification III or IV).
