Abstract

*Pseudomonas syringae pv. phaseolicola* is the causative agent of halo blight in the common bean, *Phaseolus vulgaris*. *P. syringae pv. phaseolicola* race 4 strain 1302A contains the avirulence gene *avrPphB* (syn. *hopAR1*), which resides on PPHGI-1, a 106 kb genomic island. Loss of PPHGI-1 from *P. syringae pv. phaseolicola* 1302A following exposure to the hypersensitive resistance response (HR) leads to the evolution of strains with altered virulence. Here we have used fluorescent protein reporter systems to gain insight into the mobility of PPHGI-1. Confocal imaging of dual-labelled *P. syringae pv. phaseolicola* 1302A strain, F532 (dsRFP in chromosome and eGFP in PPHGI-1), revealed loss of PPHGI-1:eGFP encoded fluorescence during plant infection and when grown in vitro on extracted leaf apoplastic fluids. Fluorescence-activated cell sorting (FACS) of fluorescent and non-fluorescent PPHGI-1:eGFP F532 populations showed that cells lost fluorescence not only when the GI was deleted, but also when it had excised and was present as a circular episome. In addition to reduced expression of eGFP, quantitative PCR on sub-populations separated by FACS showed that transcription of other genes on PPHGI-1 (*avrPphB* and *xer*) was also greatly reduced in F532 cells harbouring the excised PPHGI-1:eGFP episome. Our results show how virulence determinants located on mobile pathogenicity islands may be hidden from detection by host surveillance systems through the suppression of gene expression in the episomal state.

Molecular analysis of genetic interactions between *P. syringae pv. phaseolicola* and its host bean has led to the identification and characterization of a number of bacterial *avr* genes and plant *R* genes [7]. One of these *avr* genes, *avrPphB* (syn. *hopAR1*), encodes an effector protein that induces an HR in bean cultivar (cv.) Tendgreen (TG) which carries the *R3* resistance gene. In *P. syringae pv. phaseolicola* strain 1302A, *avrPphB* is located on a 106 kb genomic island (GI) designated PPHGI-1 [6]. The similarity of PPHGI-1 to other integrative and conjugative elements (ICEs) suggests that the island integrates and excises at att sites within the tRNA locus found at its borders, via an episomal circular intermediate [13,16]. PPHGI-1 can be acquired by transformation between strains of *P. syringae pv. phaseolicola* [17] and is physically lost from cells of *P. syringae pv. phaseolicola* during infection of TG undergoing the R3-AvrPphB mediated HR [18,6]. Following excision from the chromosome, a critical step in the mobilization of PPHGI-1 is formation of the circular episome that is capable of limited replication [17,19].

The plant apoplast comprises the intercellular space surrounding plant cells where metabolic and physiological processes relating to cell wall biosynthesis, nutrient transport, and stress responses occur [20]. It is also the site of colonisation for *P. syringae pv. phaseolicola* which obtains nutrients directly from apoplastic...
Results and Discussion

Creation of dual-labelled fluorescent P. syringae pv. phaseolicola strains

We aimed to visualise PPHGI-1 dynamics in the plant and in vivo using constitutively expressed fluorescent markers. Strains of P. syringae pv. phaseolicola 1302A were generated expressing fluorescent proteins encoded from PPHGI-1 (e.g. PPHGI-1::eGFP) and also from other regions of the chromosome as illustrated in Figure 1A. P. syringae pv. phaseolicola F341 contained chromosomal YFP and PPHGI-1::CFP (Figure 1B) and P. syringae pv. phaseolicola F532 chromosomal dsRFP and PPHGI-1::eGFP (Figure 1C). Loss of PPHGI-1 was expected to lead to loss of the GI encoded fluorescence but retention of emission from the other fluorophore (Figure 1D, E). P. syringae pv. phaseolicola F341 and P. syringae pv. phaseolicola F532 also displayed wildtype P. syringae pv. phaseolicola 1302A phenotypes; for example in vitro and in planta growth rates, plasmid profiles, and equal rates of PPHGI-1 loss when passed through TG (data not shown).

Confocal microscopy of dual-labelled fluorescent P. syringae pv. phaseolicola strains in leaves

We have previously described the use of bacteria separately labeled with fluorophores for confocal microscopy of infected leaves [22]. With the strains constructed to express two fluorophores, we planned to follow loss of PPHGI-1 occurring at microsites within challenged leaves and in particular during the HR in TG. Colonies of P. syringae pv. phaseolicola develop in the intercellular spaces, typically attached to leaf mesophyll cells. A feature of tissue undergoing the HR in TG was the dispersal of colonies to reveal individual bacterial cells as illustrated in Fig. 2A. When P. syringae pv. phaseolicola F532 was infiltrated into TG or CW leaves, colonies frequently showed peripheral loss of PPHGI-1::eGFP fluorescence (Figure 2B). Dispersed bacterial cells of F532 in TG and around the cut edges of leaf samples in both cultivars also displayed mixed fluorescence (Fig. 2C). The loss of fluorescence from colonies was more easily detected in the susceptible variety CW, rather than resistant TG, because imaging whole colonies after the HR was partly compromised by the accumulation of autofluorescent plant-derived metabolites (Figure 2D, [22]). Limiting initial P. syringae pv. phaseolicola inoculum concentrations in TG was effective in minimizing the spread of the HR and was necessary to avoid spectral overlap of dsRFP and HR autofluorescence.

Our observations with F532 highlighted that the outer layer(s) of bacteria within established colonies (in both TG and CW leaves) preferentially exhibit loss of PPHGI-1::eGFP fluorescence. Such colony differentiation may be due to the activities of diffusion mediated gradients similar to those proposed in biofilm models [23], where the colony periphery receives higher concentrations of diffused substrates (e.g. nutrients, oxygen, environmental stimuli, and/or antimicrobial compounds) and therefore exhibits differing metabolic activity compared with the colony centre [24]. Higher rates of in planta loss of PPHGI-1::eGFP fluorescence from the periphery of F532 colonies may be due to higher levels of environmental cue(s) from the P. vulgaris apoplast and/or due to a higher metabolic activity due to enhanced nutrient acquisition. Significantly, loss of PPHGI-1 derived fluorescence appeared to be as frequent in the susceptible CW leaves as in the resistant TG which underwent the HR. By contrast, previous work had shown that cells that have lost PPHGI-1 are more readily selected during the HR than during the development of infection in susceptible tissues such as CW leaves [6,19].

Loss of eGFP fluorescence from F532 is observed in apoplastic fluids

Lovell et al. [17] demonstrated that apoplastic fluids extracted from leaves provide a medium that promotes the mobility of PPHGI-1. To determine if PPHGI-1::eGFP fluorescence was lost...
from F532 in vitro, the strain was grown on apoplastic fluids extracted from leaves of CW and TG, mixed with agarose and coated on microscope slides to facilitate microscopy. Fluorescence was lost rapidly from colonies grown on apoplastic fluids but not from M9-based media (Figure 3). Increasing the concentration of either CW or TG apoplastic fluid in the agarose slide medium caused a corresponding increase in the frequency of loss of fluorescence due to PPHGI-1::eGFP (Figure 3A). To confirm that loss of PPHGI-1 encoded fluorescence was not specific to strain F532, P. syringae pv. phaseolicola F341 was examined in the same way and rates of loss of PPHGI-1::eCFP were comparable to those found for PPHGI::eGFP in F532 (data not shown). Clearly, some component(s) of apoplastic fluid from either cultivar promoted loss of fluorescence of respectively labeled PPHGI-1 constructs, suggesting that the occurrence of the HR is not required for the release of inducing metabolites from plant cells.

**Loss of PPHGI-1::eGFP fluorescence is not always due to loss of the GI from the bacterial cell**

To determine whether or not changes in PPHGI-1::eGFP fluorescence were due to cellular loss of PPHGI::eGFP, F532 cells were first grown on M9/TG agarose slides. Following confocal imaging to confirm loss of PPHGI-1::eGFP fluorescence from some cells but positive dsRFP fluorescence, bacteria from the imaged agarose slide were resuspended in J Ringers and cultured to individual colonies on KB agar. All resulting colonies were found to express eGFP. Furthermore, 200 colonies were analysed for the presence of avrPphB by the TG pod-stab pathogenicity assay and all colonies were found to cause the HR. This suggested that, despite the temporary loss of expression of the PPHGI-1::eGFP construct after growth on apoplastic fluids, PPHGI-1 was retained and functional.

**FACS separation of P. syringae pv. phaseolicola F532 populations based on eGFP fluorescence**

To investigate the apparent silencing of eGFP, fluorescence-activated cell sorting (FACS) was employed to obtain pure populations of F532 with or without eGFP fluorescence; F532/dsRFP, F532/GFP, respectively (Figure 4). We first tested the suitability of FACS to differentiate the fluorescent Pseudomonads. Low background was recorded in 1302A without added fluorophores (Fig. 4A) but this did not compromise the strong signal from eGFP (Fig. 4B).
To collect eGFP fluorescing and non-fluorescent bacteria, F532 cultures were grown (48 h) in stationary M9/TG apoplastic fluid (1:1) broths and 200,000 particles (events) were collected for both F532/GFP+ and F532/GFP- cells. Sub-populations were serially diluted and grown on KB+Gm and the viable cells recovered were: F532/GFP+ (2.64 × 10^4 CFU/ml) and F532/GFP- (1.06 × 10^4 CFU/ml). The decrease in viable CFU/ml from F532/GFP- events compared to F532/GFP+ was likely due to detection of non-fluorescent particles, from either non-viable F532 cells and/or plant debris from apoplastic fluid.

The separated sub-populations of F532/GFP- and F532/GFP+ cells were monitored for further changes in PPHGI-1::eGFP fluorescence over a 48 h period (in LB, static at 25°C, Figs. 4C–F). If PPHGI-1::eGFP excision and re-insertion into the chromosome was a dynamic process, we expected to see a reversion of the F532/GFP- (Figure 4 C, M1) sample to form a major population of F532/GFP+ cells, with a minor population of F532/GFP- cells. As predicted, F532/GFP- cells were observed to revert to a population of predominantly F532/GFP+ cells (Figure 4D, E) over a 48 h period. Also, F532/GFP+ cells from gated population M2 (Figure 4C) formed a sub-population of F532/GFP- cells (M1-like, Figure 4F) indicating the continued mobility of PPHGI-1::eGFP in F532. It is interesting that after 48 h both FACS sub-populations reverted back to the same general population structure (as in Figures 4E and 4F) suggesting that there may be an equilibrium between F532 cells containing PPHGI-1 in the chromosome (expressing eGFP) and F532 cells containing the excised PPHGI-1 (not expressing eGFP).

Figure 4G illustrates the changes in patterns of sorted fluorescent particles comparing F532 grown in apoplastic fluid which produces a broader GFP detection spectrum than F532 grown in LB broth. This result correlates with different levels of PPHGI-1::eGFP fluorescence (whilst dsRFP remained constant) observed in F532 cells examined by confocal microscopy (e.g. Figure 3C).

qPCR reveals correlation between increased production of the circular episome of PPHGI-1 and decreased gene expression in F532/GFP- cells

We had shown that loss of PPHGI-1::eGFP fluorescence was often not due to the deletion of PPHGI-1 from F532. Therefore, we investigated whether down-regulation of gene expression occurs after GI excision and circularization, thereby accounting for loss of PPHGI-1::eGFP fluorescence. qPCR was performed on FACS separated F532 populations to determine differences between F532/GFP- and F532/GFP+ cells by comparison of: a) the amount of PPHGI-1 forming a circular PPHGI-1 episome...
(CE); and b) the expression levels of two genes contained within PPHGI-1 (avrPphB and xerC). Results reveal that there is increased formation of CE in F532/GFP- cells, but greatly reduced expression of avrPphB and xerC (Figure 5). We conclude that loss of fluorescence from F532 does not, therefore, usually indicate loss of PPHGI-1, but is in fact reporting creation of the excised CE from which gene expression is greatly reduced. Such reduced expression of GI genes could be explained by transcriptional and translational down-regulation due to supercoiling of DNA (Figures 1D & E) [25,26] and/or possible association of histone-like proteins influencing gene expression [27,28].

Frequency of occurrence of the circular episome

It is well established that PPHGI-1 is lost from 1302A cells during the HR in bean leaves. The antimicrobial conditions generated by the HR appear to select for bacteria lacking the avirulence gene avrPphB [6,21,19]. The first stage in deletion of PPHGI-1 is its excision from the chromosome and the formation of the CE that was first detected by PCR in bacteria grown in LB [6,21,19]. Here we applied the more stringent method of qPCR to confirm the presence of CE in F532/GFP- cells (Fig. 5). The high frequency of occurrence of bacteria down-regulating gene expression on PPHGI-1 detected in vitro in apoplastic fluids suggested that bacteria harbouring the excised episome might be far more common in certain environments. We therefore used qPCR to examine the levels of PPHGI-1 CE in bacteria grown under various conditions for 5 h (Fig. 6).

The experiment revealed strikingly higher levels of CE in bacteria inoculated into bean leaves than grown in LB or minimal media. At the 5 h time point, however, there was no difference in CE concentration in resistant TG, or susceptible CW leaves. As expected, CE was present at high levels in bacteria incubated in apoplastic fluids. The highest amounts were found after growth in fluids recovered from leaves undergoing the HR and the lowest from susceptible, diseased tissue. The addition of whole leaf extracts to M9 also created conditions favouring formation of the CE.

Taken together these results suggest that excision of PPHGI-1 is promoted by a plant factor(s) but there is little differentiation between susceptible and resistant plant tissues before infection. The occurrence of the HR does appear to enhance excision and formation of the circular intermediate, but not to such an extent that would explain the high frequency of loss of PPHGI-1 during the HR [6]. We conclude that P. syringae pv. phaseolicola PPHGI-1 excision, circularisation and re-insertion is a very dynamic process necessary to maintain PPHGI-1 replication within P. syringae pv. phaseolicola populations. This would explain the variance in detectable levels of PPHGI-1::eGFP fluorescence from adjacent cells during confocal imaging (e.g. Figure 3C) where images obtained are most likely ‘snapshots’ of F532 cells at different stages of PPHGI-1::eGFP excision. It is highly likely that the excision of PPHGI-1 may interfere with the timeline of eGFP transcription, translation, protein folding, maturation and degradation – all ultimately affecting the levels of PPHGI-1::eGFP fluorescence.

The reduced expression of genes on the CE, notably avrPphB, would provide a selective advantage for the bacterial cells allowing their increased multiplication in resistant TG tissues and favouring subsequent selection of bacteria that had lost PPHGI-1. Alternatively, the multiplication of bacteria maintaining the silenced PPHGI-1 may prove advantageous should they be spread to other plants lacking the R3 resistance gene. The re-integration of PPHGI-1 into the chromosome would lead to a return to normal levels of expression of genes encoded on the GI.

In our previous work on the mobility of PPHGI-1 we used failure to induce the HR as an indication of loss of the island and confirmed this result by PCR-based diagnostics [6]. Our results on the suppression of gene expression from the circularised episome show that there is a complex pattern of selection occurring within the infected plant. Because we have demonstrated movement of the island both out of and back into the chromosome, there must be a resultant fluctuation in levels of expression of avrPphB. It would only be those bacteria that have physically lost PPHGI-1 that would retain virulence during colonisation and presumably
Figure 4. Fluorescence-activated cell sorting (FACS) separation of *P. syringae pv. phaseolicola* cells based on fluorescent protein expression. Histograms record fluorescence detected by the FL1-H detector after analysis of 200,000 particles (events). Analysis of A. *P. syringae pv. phaseolicola* 1302A grown in M9, 48 h. B. *P. syringae pv. phaseolicola* SG248 with constitutive eGFP introduced chromosomally, grown in M9, 48 h. and C. *P. syringae pv. phaseolicola* F532 grown in M9/TG apoplastic fluid (1:1) for 48 h. Gating was performed to collect equal populations of (M1) *P. syringae pv. phaseolicola* F532 that did not express eGFP and (M2) eGFP expressing *P. syringae pv. phaseolicola* F532. Gated subpopulations were then grown in LB to investigate changes in PPHGI-1:eGFP expression. D. Population M1, after incubation for 24 h, note the presence of eGFP fluorescing bacteria. E. M1 after 48 h and F. Population M2 after 48 h. G. An overlay of GFP detection from F532 grown in LB (Green) and F532 grown in M9/TG apoplastic fluid (1:1) for 48 h (dark blue). Counts refer to fluorescence intensity. The arrow denotes region corresponding to F532 cells with reduced PPHGI-1:eGFP expression. Similar background fluorescence was observed in all media.
doi:10.1371/journal.ppat.1002010.g004

Figure 5. Gene expression and circular episome detection in sub-populations of *P. syringae pv. phaseolicola*. Analysis of FACS-separated sub-populations of F532 expressing GFP (F532/GFP+) and F532 without GFP fluorescence (F532/GFP-) shows: A. F532/GFP- has effectively no expression of *avrPphB*. B. *xerC* expression is also reduced in F532/GFP-; and C. PPHGI-1 circular episome formation is significantly greater in F532/GFP- cells than F532/GFP+ cells. All data were standardized by simultaneous qPCR analysis of *gyrB* expression and error bars represent standard error of the mean of three experimental replicates. Letters above bars indicate significant differences at p<0.05 assessed with Student’s t test.
doi:10.1371/journal.ppat.1002010.g005
break out from sites undergoing the effector-triggered HR. In order to
dissect the dynamics further we need to investigate the
mechanisms controlling deletion of the island in more detail.

The initial aim of our work was to use confocal microscopy to
examine PPHGI-1 deletion at micro-sites within infected leaves. We
were only partially successful because of the suppression of gene
expression from the excised episome. However, our findings may be
of more general significance to our understanding of microbial pathogenicity.
Dynamic excision and reinsertion of GIs has been
described in other Pseudomonas species [29,30]. We suggest that the
silencing of genes carried on GIs following excision from their
cromosomal location may be an important strategy utilized not
only by P. syringae pv. phaseolicola but also by other bacterial pathogens of plants and animals. Switching off gene expression after
GI excision is a novel mechanism with an enormous biological
potential. It may, for example, represent a new way to modulate

**Materials and Methods**

**Bacterial strains, plasmids and culture media**

Bacterial strains and plasmids used in this study are listed in
Table 1. *Escherichia coli* strains were grown at 37°C in Luria Bertani
(LB, Difco) media and *Pseudomonas* strains were grown at 25°C on
Kings medium B (KB) [31], in LB broth or M9 minimal medium
(M9,[32]). Antibiotics were used at the following concentrations
(mg/ml): gentamycin (Gm) 10, kanamycin (Km) 50, ampicillin (Ap)
100, nitrofurantoin (NF) 100, and rifampicin (Rif) 100.

**DNA isolation, PCR and plasmid extractions**

Plasmid DNA was isolated from a pure bacterial culture using
the QIAprep Spin Miniprep Kit (Qiagen) and restriction
enzymatic digests performed as per manufacturers protocols
(NEB biolabs). Unless stated otherwise, standard PCR reactions
were performed using Phusion TM polymerase (NEB biolabs)
using recommended cycle parameters with oligonucleotide
primers (Table S1). Automated DNA sequencing was performed
with an ABI 3130xl genetic analyser. *P. syringae* pv. *phaseolicola* plasmid profiles were determined by extracting total uncut plasmid
DNA from overnight cultures as described previously [33].

**Insertion of eGFP/eCFP into PPHGI-1**

Strand overlapping extension PCR [34] was used to introduce the
rare cutting restriction enzyme sites *PmeI* and *PacI* into a non-
coding-region (NCR; 55667 bp – 56577 bp, Genbank accession
AJ870974) of DNA within PPHGI-1 for introduction of eGFP or
eCFP (Figure 1A). Three transcriptional terminators (TTs) in each
translational frame were introduced upstream of *PmeI* and
downstream of *PacI* (Figure 1A). Overlapped PCR products were
cloned into pK18mobsacB [35] to create pSG028-1. Both eGFP
and eCFP were PCR amplified from AKN100 and AKN033
respectively using primers (Table S1) that were designed to introduced *PmeI* and *PacI* restriction sites respectively at amiplice terminal ends. PCR
products were cloned into Zero-Blunt-Topo (Invitrogen) to create
pSG097 (eGFP) and pSG103 (eCFP). *PmeI* and *PacI* digests of
pSG097 and pSG103 were respectively digested into similar
digested pSG028-1 to create pSG111-eGFP and pSG114-eCFP.
Introduction of the eGFP (pSG111-eGFP) and eCFP (pSG114-
eCFP) into the NCR of PPHGI-1 was achieved by allelic exchange
[36] with *P. syringae* pv. *phaseolicola* 1302A to create KmR first cross-
over construct strains, *P. syringae* pv. *phaseolicola* SG120 (eGFP) and
*P. syringae* pv. *phaseolicola* SG126 (eCFP). *P. syringae* pv. *phaseolicola* SG120 and *P. syringae* pv. *phaseolicola* SG126 were confirmed to
have *P. syringae* pv. *phaseolicola* 1302A wild type phenotypes as
described previously [6].

**Chromosomal introduction of fluorescent proteins**

dsRFP (AKN132, Table 1) and eYFP (AKN069) were introduced respectively into *P. syringae* pv. *phaseolicola* SG120 and *P. syringae* pv.
*phaseolicola* SG126 via the Tn7 transposon delivery system kindly
provided by Lambertsen et al. [36] as described previously [22] to
create *P. syringae* pv. *phaseolicola* F341 (P. syringae pv. *phaseolicola* 1302A
![Figure 6. Environmental effects on the detection of the PPHGI-1 circular episome determined by qPCR.](image-url)
with chromosomal eYFP and PPHGI-1::eGFP, Figure 1B) and *P. syringae* pv. *phaseolicola* F532 (*P. syringae* pv. *phaseolicola* 1302A with chromosomal dsRFP and PPHGI-1::eGFP, Figure 1C).

### In planta confocal imaging and data collection

*P. syringae* pv. *phaseolicola* inoculations and *in planta* confocal imaging of *P. syringae* pv. *phaseolicola* fluorescence in *P. vulgaris* was performed essentially as described previously [22]. Confocal visualisation of *in planta* infiltration of dual-labelled strains (F532 and F341) was performed on the Leica TCS-SP2-DM IRE2 confocal laser scanning microscope (Leica Microsystems Wetzlar GmbH) at 25× or 40× (objective magnification) for colony morphology and 63× or 100× for visualisation of individual cell dispersal. Variable AOTF filters were used for the following fluorophores (excitation/emission): eYFP (514 nm/525–600 nm); eGFP (488 nm/516–539 nm); dsRFP (568 nm/600–644 nm); and for plant autofluorescence (440 nm, 650–785 nm). Z-series imaging was performed at intervals of 0.3 μm (individual cells) and 1 μm (colonies). All confocal images were assigned false colour in images (eCFP cyan, eGFP green, eYFP yellow, dsRFP red and plant tissue blue). 1 μm z-section scan intervals were used to ensure all bacterial fluorescence was analysed. Three 5 mm² leaf samples were analysed from each variable and each sample had at least 12 random areas confocal imaged to ensure representative data.

### P. syringae pv. phaseolicola growth and visualisation on agarose slides

Glass slides were layered with approximately 0.17 mm of agarose (2.2% final volume) containing desired liquid (ddH₂O, M9, or apoplastic fluid) and used immediately. Apoplastic fluid was extracted from 10 day old TG or CW bean leaves, infiltrated CW leaves undergoing disease or TG leaves undergoing the HR as described previously [17]. All apoplastic fluids were used immediately after preparation following filter-sterilization (0.2 μm). Overnight cultures were washed and serially diluted in 1/4 Ringers solution to OD₆₀₀ equivalent of: 1×10⁻², 10⁻⁴, 10⁻⁶, or 10⁻⁸. Inoculum droplets (10 μl) were placed onto respective agarose slides and incubated within a sterile sealed container (containing high humidity) at 25°C for 24 h–144 h as required. The optimal micro-colony development was usually observed at (0.2 μm). Overnight cultures were washed and serially diluted in 1/4 Ringers solution to OD₆₀₀ equivalent of: 1×10⁻², 10⁻⁴, 10⁻⁶, or 10⁻⁸. Inoculum droplets (10 μl) were placed onto respective agarose slides and incubated within a sterile sealed container (containing high humidity) at 25°C for 24 h–144 h as required. The optimal micro-colony development was usually observed at

### Agarose recovery of *P. syringae* pv. *phaseolicola* F532 cells with loss of PPHGI-1::eGFP fluorescence

*P. syringae* pv. *phaseolicola* F532 were inoculated (1×10⁻⁴ OD₆₀₀) onto M9/TG slides for 48 h. Agarose

**Plasmids**

- **pRK2013**: Helper plasmid for conjugation, KmR
- **AKN033**: Vector containing Tn7 containing eCFP, ApR, GmR
- **AKN069**: Vector containing Tn7 containing eYFP, ApR, GmR
- **AKN100**: Vector containing Tn7 containing eGFP, ApR, GmR
- **AKN132**: Vector containing Tn7 containing dsRFP, ApR, GmR
- **pUX8BF13**: Helper plasmid for Tn7 transposition functions, ApR
- **pK18moblacB**: Suicide delivery vector containing sacB, KmR
- **ZERO-BLUNT-TOPO**: Blunt end PCR cloning vector
- **pSG028-1**: ZERO-BLUNT-TOPO + OE-PCR-RCR (containing PacI, Pmel, SpeI, and AsiSI cloning sites) flanked by HindIII-Xbcl
- **pSG068-9**: pK18moblacB + HindIII-Xbcl cloned NCR-OE-PCR-RCS, (containing PacI, Pmel, SpeI, and AsiSI cloning sites), KmR
- **pSG097**: PacI-Pmel flanked efp (ex AKN100) amplicon cloned in ZERO-BLUNT-TOPO, KmR
- **pSG103**: PacI-Pmel flanked efp (ex AKN033) amplicon cloned in ZERO-BLUNT-TOPO, KmR
- **pSG111**: pSG068-9 containing PacI-Pmel cloned eGFP, KmR
- **pSG114**: pSG068-9 containing PacI-Pmel cloned eCFP, KmR

ApR, RifR, KmR indicate resistance to ampicillin, gentamicin, and kanamycin respectively.
slides were imaged using both dsRFP and eGFP channels to ensure *P. syringae* pv. *phaseolicola* F532 cells had loss of PPHGI-1: eGFP fluorescence (F532/GFP samples were serially diluted and plated onto KB using confocal microscopy to confirm status of eGFP and dsRFP)

**Fluorescence-activated cell sorting (FACS) separation of *P. syringae* pv. *phaseolicola* F532 populations based on eGFP fluorescence**

*P. syringae* pv. *phaseolicola* F532 was grown in broth cultures consisting of: M9/TG apoplastic fluid (1:1). 200,000 particles (events) were collected for both F532/GFP+ and F532/GFP- samples were serially diluted and plated onto KB+Gm to correlate FACS events with viable *P. syringae* pv. *phaseolicola* cell recovery. FACS was performed on either (1) a FACS Vantage cell sorter (Becton Dickinson), equipped with a 488 nm argon laser; or (2) an Influx cell sorter (Becton Dickinson). *P. syringae* pv. *phaseolicola* F532 cultures were separated based on GFP fluorescence (F532/GFP+) and non-GFP fluorescence (F532/GFP−). Both F532/GFP+ and F532/GFP− FACS sub-populations were analysed immediately using confocal microscopy to confirm status of eGFP and dsRFP fluorescence.

**qPCR of xerC and avrPphB expression and circular episome (CE) production**

qPCR was used to quantify *xerC* and *avrPphB* expression and PPHGI-1 CE production in vitro and in planta. *P. syringae* pv. *phaseolicola* strains were added to respective growth medium (either LB, M9, apoplastic fluid and/or M9/apoplastic fluid mixes) and after 5 h, cells were harvested and gene expression stopped using RNA/DNA lysis solution (Gentra Systems, UK) or DNA lysis solution (Gentra, UK) followed by a second DNase step of 15 min at 37 °C (Promega, UK). cDNA was synthesised using the TaqMan Reverse Transcription Reagents kit (Applied Biosystems). For quantification of the PPHGI-1 CE, DNA was extracted using the Puregene DNA isolation kit (Gentra Systems, UK). Triplicate samples were taken for each sample for cDNA/DNA synthesis, and each sample was analyzed twice in separate amplifications. cDNA and DNA were quantified using a Nanodrop spectrophotometer (Thermo Scientific, USA) and adjusted to 100 ng/µl.

When gene expression was analysed after FACS separation, cells were sorted directly into either RNA protect reagent (Qiagen UK) or DNA lysis solution (Gentra Systems, UK) and RNA/DNA extracted as above. qPCR was performed on an ABI 7300 Real-Time PCR System (Applied Biosystems), calibrated using 7300 Real-Time PCR Systems Spectral Calibration kit (Applied Biosystems) and probes (Table S1) were labelled with 3′ FAM and 5′ TAMRA TaqMan dyes. Reaction volume (% µl) consisted of 12.5 µl TaqMan PCR mastermix (Applied Biosystems), 2 µl each primer (10 µM), 2 µl probe (5 µM) and 6.5 µl RNase free water. Standard qPCR cycling conditions were 50 °C for 2 min, 95 °C for 10 min and 40 × cycles of 95 °C for 15 sec followed by 60 °C for 1 min. Results were analysed using ABI 7300 System SDS software (Applied Biosystems) and compared using JMP IN 7.0 statistical analysis software (www.jmpin.com). Average abundance of xerC and avrPphB RNA and CE DNA were expressed relative to levels of gyrB.

**Supporting Information**

**Table S1** Oligonucleotide primers used in this study.
