(Dated: February 8, 2011)

We have analytically solved the LO pQCD (leading order perturbative QCD) singlet DGLAP (Dokshitzer, Gribov, Lipatov, Alterelli, Parisi) equations $\xi_\xi$ using Laplace transform techniques. Newly-developed highly accurate numerical inverse Laplace transform algorithms $\xi_\xi$ allow us to write fully decoupled solutions for the singlet structure function $F_s(x,Q^2)$ and $G(x,Q^2)$ as

$$F_s(x,Q^2) = F_s(F_{00}(x_0), G_0(x_0)) \quad \text{and} \quad G(x,Q^2) = G(F_{00}(x_0), G_0(x_0)), $$

where the $x_0$ are the Bjorken-$x$ values at $Q_0^2$. Here $F_s$ and $G$ are known functions—found using LO DGLAP splitting functions—of the initial boundary conditions $F_{00}(x) \equiv F_s(x, Q_0^2)$ and $G_0(x) \equiv G(x, Q_0^2)$, i.e., the chosen starting functions at the virtuality $Q_0^2$. For both $G(x)$ and $F_s(x)$, we are able to either devolve or evolve each separately and rapidly, with very high numerical accuracy, a computational fractional precision of $O(10^{-9})$. Armed with this powerful new tool in the pQCD arsenal, we compare our numerical results from the above equations with the published MSTW2008 and CTEQ6L LO gluon and singlet $F_s$ distributions $\xi_\xi$, starting from their initial values at $Q_0^2 = 1 \text{ GeV}^2$ and $1.69 \text{ GeV}^2$, respectively, using their choices of $\alpha_s(Q^2)$. This allows an important independent check on the accuracies of their evolution codes and therefore the computational accuracies of their published parton distributions. Our method completely decouples the two LO distributions, at the same time guaranteeing that both $G$ and $F_s$ satisfy the singlet coupled DGLAP equations. It also allows one to easily obtain the effects of the starting functions on the evolved gluon and singlet structure functions, as functions of both $Q^2$ and $Q_0^2$, being equally accurate in deviation ($Q^2 < Q_0^2$) as in evolution ($Q^2 > Q_0^2$). Further, it can also be used for non-singlet distributions, thus giving LO analytic solutions for individual quark and gluon distributions at a given $x$ and $Q^2$, rather than the numerical solutions of the coupled integral-differential equations on a large, but fixed, two-dimensional grid that are currently available.

I. INTRODUCTION

The search for new physics at the LHC demands an accurate knowledge of gluon distribution functions at small Bjorken $x$ and large virtuality $Q^2$, both for estimating QCD backgrounds and for calculating gluon-initiated processes. The traditional method has simultaneously determined gluon and quark distribution functions by fitting experimental data on neutral- and charged-current deep inelastic scattering processes and some jet data over a large domain of values of $x$ and $Q^2$. The distributions at small $x$ and large $Q^2$ are determined mainly by the proton structure function $F_2^\gamma p(x,Q^2)$ measured in deep inelastic $ep$ (or $\gamma p$) scattering. The fitting process starts with an initial $Q_0^2$, typically less than or equal to the square of the $c$ quark mass, $m_c^2 \approx 2 \text{ GeV}^2$, and individual quark and gluon trial distributions parameterized with pre-determined shapes, given as functions of $x$ for the chosen $Q_0^2$. The distributions are then evolved numerically on a finite, albeit large, two-dimensional grid in $x$ and $Q^2$ to larger $Q^2$ using the coupled integral-differential DGLAP equations $\xi_\xi$, typically in leading order (LO) and next-to-leading order (NLO), and the results used to predict measured quantities. The final distributions are then determined by adjusting the input parameters to obtain a best fit to experimental data, fitting both HERA and Tevatron data over a large range of $x$ and $Q^2$, along with selected hard scattering data from fixed target experiments. This procedure is very indirect in the case of the gluon: the gluon distribution $G(x,Q^2) = xg(x,Q^2)$ does not contribute directly to the accurately determined structure function $F_2^\gamma p(x,Q^2)$, and is determined only through the quark distributions in conjunction with the evolution equations, or at large $x$, from jet data. For recent determinations of the gluon and quark distributions, see $\xi_\xi$.

In the following, we will summarize our method for analytically determining $G(x,Q^2)$ and the singlet structure function $F_s(x,Q^2)$ directly and individually, using as input $G_0(x) \equiv G(x,Q_0^2)$ and $F_{00}(x) \equiv F_s(x,Q_0^2)$, where $Q_0^2$ is
order to test the numerical accuracy of their evolution codes, we consider two cases, using the published LO starting
values \( Q_0^2 = 1 \text{ GeV}^2 \), we transform the solutions back into

\[
G(x, Q^2) = x g(x, Q^2)
\]

distributions. In order to test the numerical accuracy of their evolution codes, we consider two cases, using the published LO starting
distributions for both groups at \( Q^2 = 1 \text{ GeV}^2 \), noting that the CTEQ6L LO gluon distribution turns over and goes negative at small \( x \), i.e., \( x \leq 5 \times 10^{-5} \), whereas the MSTW2008 LO gluon starting distribution continues to rise sharply at small \( x \).

II. DECOUPLING THE COUPLED LO SINGLET DGLAP EQUATIONS

Our approach uses a somewhat unusual application of Laplace transforms, in which we first introduce the variable \( v \equiv \ln(1/x) \) into the coupled DGLAP equations, then Laplace transform these coupled integral-differential equations in \( v \) space to obtain coupled homogeneous first-order differential equations in the Laplace-space variable \( s \).

We solve these equations analytically. Finally, using fast and accurate numerical inverse Laplace transform algorithms, we transform the solutions back into \( v \) space, and, finally, into Bjorken \( x \)-space, so that we can write

\[
F_s(x, Q^2) = F_s(F_0(x_0), G_0(x_0)) \quad \text{and} \quad G(x, Q^2) = G(F_0(x_0), G_0(x_0)),
\]

where the functions \( F \) and \( G \) are determined by the splitting functions in the DGLAP equations, with \( x_0 \) being the Bjorken-\( x \) at the starting virtuality \( Q_0^2 \); \( F_0(x) \) and \( G_0(x) \) are the known starting distributions at \( Q^2 = Q_0^2 \), where evolution (devolution) begins.

Our method can be generalized to NLO (see Ref. [14]), but for brevity, we will limit ourselves to LO in this paper. We write the coupled LO DGLAP equations as

\[
\frac{4\pi}{\alpha_s(Q^2)} \frac{\partial F_s}{\partial \ln Q^2}(x, Q^2) = 4F_s(x, Q^2) + \frac{16}{3} F_s(x, Q^2) \ln \frac{1-x}{x} + \frac{16}{3} x \int_x^1 \left( \frac{F_s(z, Q^2)}{z} - \frac{F_s(x, Q^2)}{x} \right) \frac{dz}{z-x} \left( \frac{8}{3} x \int_x^1 F_s(z, Q^2) \left( 1 + \frac{x}{z} \right) \frac{dz}{z^2} + 2n_f x \int_x^1 G(z, Q^2) \left( 1 - \frac{2}{z^2} + 2 \frac{x}{z^2} \right) \frac{dz}{z^2} \right),
\]

\[
\frac{4\pi}{\alpha_s(Q^2)} \frac{\partial G}{\partial \ln Q^2}(x, Q^2) = \frac{33 - 2n_f}{3} G(x, Q^2) + 12G(x, Q^2) \ln \frac{1-x}{x} + 12x \int_x^1 \left( \frac{G(z, Q^2)}{z} - \frac{G(x, Q^2)}{x} \right) \frac{dz}{z-x} \left( 12 \int_x^1 \frac{G(z, Q^2)}{z} \frac{dz}{z^2} + 8 \int_x^1 F_s(z, Q^2) \left( 1 + \frac{1-x}{z} \right) \frac{dz}{z} \right).
\]

Here \( \alpha_s(Q^2) \) is the running strong coupling constant, and for LO MSTW2008 is given by the LO form

\[
\alpha_s(Q^2) = \frac{4\pi}{(11 - \frac{2}{3} n_f) \ln(Q^2/\Lambda_5^2)},
\]

with \( n_f \) the number of quark flavors. The QCD parameter \( \Lambda_5 \) is fixed so that the known \( \alpha_s(M_Z^2) \) is reproduced and then \( \Lambda_4 \) and \( \Lambda_3 \) are adjusted so that \( \alpha_s \) is continuous across the boundaries \( Q^2 = M_b^2 \) and \( M_c^2 \), respectively, where \( M_b \) and \( M_c \) are the masses of the \( b \) and \( c \) quarks. Later, we will also introduce the NLO form of \( \alpha_s \) used (with \( \alpha_s(M_Z^2) = 0.118 \)) in their LO CTEQ6L evolution, when we discuss CTEQ6L pdfs.
We now examine the last two terms of line 1 in Eq. (2) and rewrite them, introducing the variable changes $v = \ln(1/x)$, $w = \ln(1/z)$, and the notation $\hat{F}_s(v, Q^2) \equiv F_s(e^{-v}, Q^2), \hat{G}(v, Q^2) \equiv G(e^{-v}, Q^2)$, as

$$
\frac{16}{3} \hat{F}_s(v, Q^2) \ln(e^v - 1) + \frac{16}{3} \int_0^v \left( \hat{F}_s(w, Q^2) - \hat{F}_s(v, Q^2)e^{v-w} \right) \frac{1}{e^{v-w}-1} dw
$$

$$
= \frac{16}{3} \int_0^v \frac{\partial \hat{F}_s}{\partial w}(w, Q^2) \ln \left( 1 - e^{-(v-w)} \right) dw.
$$

(5)

where the final result—the last line in Eq. (5)—is found by replacing the upper limit $v$ in integral of line 1 of Eq. (5) by $v - \epsilon$, carrying out the integrals, doing a partial integration and finally, taking the limit as $\epsilon \to 0$. Similarly, we find for the last two terms of line 1 in Eq. (3), that

$$
12\hat{G}(v, Q^2) \ln(e^v - 1) + 12 \int_0^v \left( \hat{G}(w, Q^2) - \hat{G}(v, Q^2)e^{v-w} \right) \frac{1}{e^{v-w}-1} dw
$$

$$
= 12 \int_0^v \frac{\partial \hat{G}}{\partial w}(w, Q^2) \ln \left( 1 - e^{-(v-w)} \right) dw.
$$

(6)

We now rewrite Eq. (2) and Eq. (3) in terms of the new variable $v$ as

$$
\frac{4\pi}{\alpha_s(Q^2)} \frac{\partial \hat{F}_s}{\partial \ln Q^2}(v, Q^2) = 4\hat{F}_s(v, Q^2) + \frac{16}{3} \int_0^v \frac{\partial \hat{F}_s}{\partial w}(w, Q^2) \ln \left( 1 - e^{w-v} \right) dw
$$

$$
- \frac{8}{3} \int_0^v \hat{F}_s(w, Q^2) \left( e^{-(v-w)} + e^{-2(v-w)} \right) dw
$$

$$
+2n_f \int_0^v \hat{G}(w, Q^2) \left( e^{-(v-w)} - 2e^{-2(v-w)} + 2e^{-3(v-w)} \right) dw,
$$

(7)

$$
\frac{4\pi}{\alpha_s(Q^2)} \frac{\partial \hat{G}}{\partial \ln Q^2}(v, Q^2) = \frac{33 - 2n_f}{3} \hat{G}(v, Q^2) + 12 \int_0^v \frac{\partial \hat{G}}{\partial w}(w, Q^2) \ln \left( 1 - e^{v-w} \right) dw
$$

$$
+12 \int_0^v \hat{G}(w, Q^2) \left( 1 - 2e^{-(v-w)} + e^{-2(v-w)} - e^{-3(v-w)} \right) dw
$$

$$
+ \frac{8}{3} \int_0^v \hat{F}_s(w, Q^2) \left( 1 + \left( 1 - e^{-(v-w)} \right)^2 \right) dw.
$$

(8)

The DGLAP equations have now been written in a form such that all of the integrals in Eq. (7) and Eq. (8) are manifestly seen to be convolution integrals. Thus, introducing Laplace transforms allows us to factor these convolution integrals, since the Laplace transform of a convolution is the product of the Laplace transforms of the factors, i.e.,

$$
\mathcal{L} \left[ \int_0^v F[w]H[v-w] dw; s \right] = \mathcal{L} \left[ \int_0^v F[v-w]H[w] dw; s \right] \mathcal{L}[F[v]; s] \times \mathcal{L}[H[v]; s].
$$

(9)

Defining the Laplace transforms of $\hat{F}_s(v, Q^2)$ and $\hat{G}(v, Q^2)$ in $s$ space as

$$
f(s, Q^2) \equiv \mathcal{L} \left[ \hat{F}_s(v, Q^2); s \right] = \int_0^\infty \hat{F}_s(v, Q^2)e^{-sv} dv, \quad g(s, Q^2) \equiv \mathcal{L} \left[ \hat{G}(v, Q^2); s \right] = \int_0^\infty \hat{G}(v, Q^2)e^{-sv} dv
$$

and noting that

$$
\mathcal{L} \left[ \frac{\partial \hat{F}_s}{\partial w}(w, Q^2); s \right] = sf(s, Q^2), \quad \mathcal{L} \left[ \frac{\partial \hat{G}}{\partial w}(w, Q^2); s \right] = sg(s, Q^2),
$$

(11)

since $F_s(v = 0, Q^2) = G(v = 0, Q^2) = 0$, we now factor the Laplace transforms of Eq. (7) and Eq. (8) into two coupled first order differential equations in Laplace space $s$ having $Q^2$-dependent coefficients. These can be written as

$$
\frac{\partial f}{\partial \ln Q^2}(s, Q^2) = \frac{\alpha_s(Q^2)}{4\pi} \Phi_f(s, Q^2)f(s, Q^2) + \frac{\alpha_s(Q^2)}{4\pi} \Theta_f(s)g(s, Q^2),
$$

(12)

$$
\frac{\partial g}{\partial \ln Q^2}(s, Q^2) = \frac{\alpha_s(Q^2)}{4\pi} \Phi_g(s, Q^2)g(s, Q^2) + \frac{\alpha_s(Q^2)}{4\pi} \Theta_g(s)f(s, Q^2).
$$

(13)
The coefficient functions $\Phi$ and $\Theta$ are given by

\[
\Phi_f(s) = 4 - \frac{8}{3} \left( \frac{1}{s+1} + \frac{1}{s+2} + 2(\psi(s+1) + \gamma_E) \right),
\]

\[
\Theta_f(s) = 2n_f \left( \frac{1}{s+1} - \frac{2}{s+2} + \frac{2}{s+3} \right),
\]

\[
\Phi_g(s) = \frac{33 - 2nf}{3} + 12 \left( \frac{1}{s+1} - \frac{1}{s+2} + \frac{1}{s+3} - \psi(s+1) - \gamma_E \right),
\]

\[
\Theta_g(s) = \frac{8}{3} \left( \frac{2}{s} - \frac{2}{s+1} + \frac{1}{s+2} \right),
\]

where $\psi(x)$ is the digamma function and $\gamma_E = 0.5772156\ldots$ is Euler’s constant.

The solution of the coupled equations in Eq. (12) and Eq. (13) in terms of initial values of the functions $f$ and $g$, specified as functions of $s$ at virtuality $Q_0^2$, is straightforward. The $Q^2$ dependence of the solutions is expressed entirely through the function

\[
\tau(Q^2, Q_0^2) = \frac{1}{4\pi} \int_{Q_0^2}^{Q^2} \alpha_s(Q^2) d\ln Q^2.
\]

With the initial conditions $f_0(s) \equiv f(s, Q_0^2)$ and $g_0(s) \equiv g(s, Q_0^2)$, the solutions are

\[
f(s, \tau) = k_{ff}(s, \tau)f_0(s) + k_{fg}(s, \tau)g_0(s),
\]

\[
g(s, \tau) = k_{gg}(s, \tau)g_0(s) + k_{gf}(s, \tau)f_0(s),
\]

where the coefficient functions in the solution are

\[
k_{ff}(s, \tau) = e^{\tau(\Phi_f(s) + \Phi_f(s))} \left[ \cosh \left( \frac{\tau}{2} R(s) \right) + \frac{\sinh \left( \frac{\tau}{2} R(s) \right)}{R(s)} (\Phi_f(s) - \Phi_g(s)) \right],
\]

\[
k_{fg}(s, \tau) = e^{\tau(\Phi_f(s) + \Phi_g(s))} \left[ \frac{2 \sinh \left( \frac{\tau}{2} R(s) \right)}{R(s)} \Theta_f(s) \right],
\]

\[
k_{gg}(s, \tau) = e^{\tau(\Phi_f(s) + \Phi_g(s))} \left[ \cosh \left( \frac{\tau}{2} R(s) \right) - \frac{\sinh \left( \frac{\tau}{2} R(s) \right)}{R(s)} (\Phi_f(s) - \Phi_g(s)) \right],
\]

\[
k_{gf}(s, \tau) = e^{\tau(\Phi_f(s) + \Phi_g(s))} \left[ \frac{2 \sinh \left( \frac{\tau}{2} R(s) \right)}{R(s)} \Theta_g(s) \right],
\]

with $R(s) \equiv \sqrt{(\Phi_f(s) - \Phi_g(s))^2 + 4\Theta_f(s)\Theta_g(s)}$. Clearly, the fundamental solutions in Laplace space $s$, Eq. (11) and Eq. (20), are symmetric under the interchange $f \leftrightarrow g$.

Let us now define four kernels $K_{FF}$, $K_{FG}$, $K_{GF}$ and $K_{GG}$, the inverse Laplace transforms of the $k$’s, i.e.,

\[
K_{FF}(v, \tau) \equiv L^{-1}[k_{ff}(s, \tau); v], \quad K_{FG}(v, \tau) \equiv L^{-1}[k_{fg}(s, \tau); v],
\]

\[
K_{GG}(v, \tau) \equiv L^{-1}[k_{gg}(s, \tau); v], \quad K_{GF}(v, \tau) \equiv L^{-1}[k_{gf}(s, \tau); v].
\]

It is evident from Eqs. (18), 22, and 24 that $K_{FG}$ and $K_{GF}$ vanish for $Q^2 = Q_0^2$ where $\tau(Q^2, Q_0^2) = 0$. It can also be shown without difficulty that for $\tau = 0$, $K_{FF}(v, 0) = K_{GG}(v, 0) = \delta(v)$ and that $K_{FG}(v, 0) = K_{GF}(v, 0) = 0$.

The initial boundary conditions at $Q_0^2$ are given by $F_{sO}(x) = F_s(x, Q_0^2)$ and $G_{sO}(x) = G_s(x, Q_0^2)$. In $v$-space, $\tilde{F}_{sO}(v) \equiv F_{sO}(e^{-v})$ and $\tilde{G}_{sO}(v) \equiv G_{sO}(e^{-v})$ are the inverse Laplace transforms of $f_0(s)$ and $g_0(s)$, respectively, i.e.,

\[
\tilde{F}_{sO}(v) \equiv L^{-1}[f_0(s); v] \quad \text{and} \quad \tilde{G}_{sO}(v) \equiv L^{-1}[g_0(s); v].
\]

Finally, we can write our decoupled singlet structure function $\tilde{F}$ and $\tilde{G}$ solutions in $v$-space in terms of the convolution integrals as

\[
\tilde{F}(v, Q^2) = \int_0^v K_{FF}(v - w, \tau(Q^2, Q_0^2)) \tilde{F}_{sO}(w) \, dw + \int_0^v K_{FG}(v - w, \tau(Q^2, Q_0^2)) \tilde{G}_{sO}(w) \, dw,
\]

\[
\tilde{G}(v, Q^2) = \int_0^v K_{GG}(v - w, \tau(Q^2, Q_0^2)) \tilde{G}_{sO}(w) \, dw + \int_0^v K_{GF}(v - w, \tau(Q^2, Q_0^2)) \tilde{F}_{sO}(w) \, dw.
\]
We now derive an alternate form of the solution to the decoupled equation, very useful for computational purposes, that does not use the convolution theorem. Using a suitable fast and accurate numerical inverse Laplace transform \(L^{-1}\), we can directly invert Eq. (28) and Eq. (29), since \(f_0(s)\) and \(g_0(s)\)—the Laplace transforms of the known starting functions \(F_{s0}(v, Q^2)\) and \(G_0(v, Q^2)\)—are readily obtainable; the coefficient functions, the \(k\)'s given in Eq. (31), are known functions of \(s\) and \(\tau\), and hence, of \(Q^2\) and \(Q_0^2\). Thus we finally write our decoupled analytic solution in \(v\) space as

\[
\hat{F}_{s}(v, Q^2) = L^{-1}[ (k_{ff}(s, \tau) f_0(s) + k_{fg}(s, \tau) g_0(s) ); v], \tag{30}
\]

\[
\hat{G}(v, Q^2) = L^{-1}[ (k_{gg}(s, \tau) g_0(s) + k_{fg}(s, \tau) f_0(s) ); v]. \tag{31}
\]

In order to use our solution in the integral representation of Eq. (28) and Eq. (29), we must first numerically invert Laplace transforms of the type of \(k_{ff}\) and \(k_{gg}\) that for small \(\tau\) look similar to Dirac \(\delta\) functions; a formidable numerical task that is inherently inaccurate, and is thus computationally intensive and significantly slower (but possible) using the numerical inverse transforms of Ref. [5]. On the other hand, if we use Eq. (30) and Eq. (31), we only have to invert a function whose inverse Laplace transform \((\hat{F}_{s}(v, Q^2)\) or \(\hat{G}(v, Q^2)\)) is very smooth and thus can be well approximated by a high order polynomial in \(v\). As shown in Ref. [5], it can then in principle be evaluated to arbitrary accuracy very rapidly. It will be shown in the Appendix that we actually achieve a fractional accuracy of \(O(10^{-11})\) in our numerical Laplace inversion. In Section V we will do a detailed evaluation of the inherent overall numerical accuracy for actual physical problems, showing that we can do both evolution and evolution rapidly to fractional accuracies of \(O(10^{-9})\) using the numerical methods outlined in the Appendix.

The final desired decoupled \(F_{s}(x, Q^2)\) and \(G(x, Q^2)\) in Bjorken-\(x\) space are readily found by substituting \(v = \ln(1/x)\) into the \(v\)-space solutions for \(\hat{F}_{s}(v, Q^2)\) and \(\hat{G}(v, Q^2)\) from Eq. (30) and Eq. (31).

### III. ANALYTIC LO NON-SINGLET DISTRIBUTIONS

For non-singlet distributions \(F_{ns}(x, Q^2)\), such as the difference between the \(u\) and \(d\) quark distributions, \(x [u(x, Q^2) - d(x, Q^2)]\), we can schematically write the logarithmic derivative of \(F_{ns}\) as the convolution of \(F_{ns}(x, Q^2)\) with the non-singlet splitting function \(K_{ns}(x)\) (using the convolution symbol \(\otimes\)), i.e.,

\[
\frac{4\pi}{\alpha_s(Q^2)} \frac{\partial F_{ns}}{\partial \ln(Q^2)}(x, Q^2) = F_{ns} \otimes K_{ns}. \tag{32}
\]

After again changing to the variable \(v = \ln(1/x)\) and going to Laplace space \(s\), we find the simple solution

\[
f_{ns}(s, \tau) = e^{\tau \Phi_{ns}(s)} f_{ns0}(s), \quad \text{where} \quad \Phi_{ns}(s) = \mathcal{L} \left[ e^{-\tau \tilde{K}_{ns}(v)}; s \right] \quad \text{and} \quad \tilde{K}_{ns}(v) = K_{ns}(e^{-v}). \tag{33}
\]

Thus we can find any non-singlet solution in \(v\)-space, using the non-singlet kernel \(K_{ns}(v) \equiv L^{-1} \left[ e^{\tau \Phi_{ns}(s)}; v \right]\), by either employing the Laplace convolution relation

\[
F_{ns}(v, Q^2) = \int_0^v K_{ns}(v - w, \tau(Q^2, Q_0^2)) \hat{F}_{ns0}(w) \, dw \tag{34}
\]

or the non-integral form

\[
F_{ns}(v, Q^2) = L^{-1} \left[ e^{\tau \Phi_{ns}(s)} f_{ns0}(s); v \right]. \tag{35}
\]

In this case, either method works equally well numerically, since the non-singlet functions \(K_{ns}(v)\) can also be approximated by a polynomial in \(v\).

For brevity, we will not pursue the case of the non-singlet solution any further here except to note that in LO the \(\Phi_{ns}(s)\) in Eq. (33) is identical to \(\Phi_f(s)\) defined in Eq. (14). Instead, we will concentrate on the more difficult case of \(F_s\) and \(G\).

### IV. LO MSTW2008 SINGLET AND GLUON DISTRIBUTIONS

As an example of the application of our analytic decoupled solutions, we will use the published MSTW2008 initial starting functions \(F_{s0}(x)\) and \(G_0(x)\) at \(Q_0^2 = 1\) GeV\(^2\) [6] and will compare our LO \(x\)-space gluon distribution \(G(x, Q^2) = \)
\(xg(x, Q^2)\) using Eq. (31) and our LO singlet structure function \(F_s(x, Q^2)\) using Eq. (30)—both numerically evaluated using a powerful new inverse Laplace transformation algorithm [4]—with the corresponding LO distributions published by the MSTW collaboration [6]. In order to insure continuity across the boundaries \(Q^2 = M_c^2\) and \(M_b^2\), we will first evolve from \(Q_0^2 = 1\) GeV\(^2\) (the MSTW \(Q_0^2\) value) to \(M_c^2\) and use our evolved values of \(G(x, M_c^2)\) and \(F_s(x, M_c^2)\) for \(new\) starting values \(G_0(x)\) and \(F_{s0}(x)\). We will then evolve to \(M_b^2\), repeating the process, thus insuring continuity of \(G\) and \(F_s\) at the boundaries where \(n_f\) changes. We use the MSTW values \(M_c = 1.40\) GeV, \(M_b = 4.75\) GeV, \(\alpha_s(1\) GeV\(^2) = 0.6818\) and \(\alpha_s(M_Z^2) = 0.13939\) in their definition of \(\alpha_s(Q^2)\) in Eq. (4).

**A. \(G(x, Q^2)\) and \(F_s(x, Q^2)\) for LO MSTW2008**

In Fig. 1 we show the LO \(x\)-space results for \(G(x, Q^2) = xg(x, Q^2)\) (upper figure) and \(F_s(x, Q^2)\) (lower figure) vs. \(x\), for 4 representative values of \(Q^2\). The \(x\)-domain, \(10^{-6} \leq x \leq 1\), is the complete region covered by the MSTW group [6]. The curves are the published LO MSTW2008 distributions [6]: from bottom to top; the (red) curve is for \(Q^2 = 5\) GeV\(^2\); the (brown) dashed curve is for \(Q^2 = 20\) GeV\(^2\); the (blue) dot-dashed curve is for \(Q^2 = 100\) GeV\(^2\); the (black) dotted curve is for \(Q^2 = M_Z^2\). The (red) dots are our analytic results for LO \(G(x, Q^2)\) from Eq. (31) and \(F_s(x, Q^2)\) from Eq. (30), after converting to \(x\)-space, using the LO MSTW2008 values for \(F_{s0}(x)\) and \(G_0(x)\); the numerical values were evaluated using Mathematica [15]. An outline of the numerical procedure is given in the Appendix.

For large \(x\), the agreement is excellent for all \(Q^2\). However, as seen in a close inspection of Fig. 1 the disagreement for both \(G\) and \(F_s\) becomes significantly large as we go to small \(x\). We will explore this in detail in Section IV B.

**FIG. 1:** Plots for LO MSTW2008 [6] gluon distributions \(G(x, Q^2) = xg(x, Q^2)\) (upper plot) and \(F_s(x, Q^2)\) distributions (lower plot) vs. Bjorken \(x\). The MSTW2008 curves are for \(Q^2 = 5, 20, 100\) and \(M_Z^2\) GeV\(^2\), bottom to top. The (red) dots are our evolution results for LO \(G(x, Q^2)\) from Eq. (31) and \(F_s\) from Eq. (30), after converting to \(x\)-space, using the LO MSTW2008 [6] values for \(F_{s0}(x)\) and \(G_0(x)\), with their choice of \(Q_0^2 = 1\) GeV\(^2\). The \(x\) range covers all of the published LO MSTW2008 \(x\) data.
B. Accuracy of evolved LO MSTW2008 distributions

We now investigate quantitatively the accuracy of the evolved LO MSTW2008 distributions ($Q^2 > Q_0^2$), introducing the fractional accuracy variable

$$\text{Fractional Accuracy} = 1 - f_i,_{\text{BDHM}} / f_i,_{\text{MSTW}}, \quad i = 1, 2,$$

(36)

where $f_1 = F_s$, $f_2 = G$, with BDHM denoting our LO analytic evaluations and MSTW denoting the published LO MSTW2008 values. We show in Fig. 2 the fractional accuracy for the LO MSTW published distributions $G(x, Q^2)$ (upper figure) and $F_s(x, Q^2)$ (lower figure) using the same four $Q^2$ values and legends used in Section IV and Fig. 1, i.e., the (red) curves are $Q^2 = 5$ GeV$^2$; the (brown) dashed curves are $Q^2 = 20$ GeV$^2$; the (blue) dot-dashed curves are $Q^2 = 100$ GeV$^2$; the (black) dotted curves are $M_Z^2$. Both the MSTW2008 $G$ and $F_s$ are in excellent agreement with our (much more numerically precise) calculations in the domain $x \sim 10^{-4}$, with a fractional accuracy of $\sim 0.1 - 0.5\%$. However, as is clearly seen in Fig. 1 for both $G$ and $F_s$ and for all $Q^2$, there is the same inaccuracy pattern in $x$, an increase of the fractional accuracy to $\sim 2\%$ down to $x \approx 8 \times 10^{-6}$, followed by a dip at $x \approx 4 \times 10^{-6}$, with a final rise to another maximum at $x \approx 2 \times 10^{-6}$ whose fractional accuracy is $\sim 12\%$. These final inaccuracies at small $x$ are quite significant. Since the $x$ patterns are essentially independent of whether we are evaluating either $G$ or $F_s$, as well as being independent of $Q^2$, they suggest that the MSTW numerical program undergoes a significant structural change at some unique value of $x$, independent of $Q^2$, that seriously degrades their numerical output, leading to large errors at small $x$. The largest errors occur at the smallest $Q^2$; at $Q_0^2$ (not shown) the error is $\sim 12 - 13\%$, and decreases monotonically to $\sim 4 - 5\%$ at the highest $Q^2$. As we will later see in Section V, there is no such pattern in the LO CTEQ6L data.

![Fractional accuracy plots for LO MSTW]
V. LO CTEQ6L SINGLET AND GLUON DISTRIBUTIONS

As a second example of the application of our analytic decoupled solutions, we will compare our LO $x$-space gluon distribution $G(x, Q^2) = xg(x, Q^2)$ from Eq. (31) and our LO singlet distribution function $F_s(x, Q^2)$ from Eq. (30)—using the published LO CTEQ6L [7] initial conditions at $Q^2_0 = 1.69$ GeV$^2$—with the corresponding LO CTEQ6L distributions [7]. In order to insure continuity across the boundary $M_b^2$, we will first evolve from $Q^2_0 = 1.69$ GeV$^2$ (the CTEQ6L $Q^2_0$ value) to $M_b^2$ and use our evolved values of $G(x, M_b^2)$ and $F_s(x, M_b^2)$ for new starting values $G_0(x)$ and $F_{s0}(x)$, thus insuring continuity of $G$ and $F_s$ at the boundary where $n_f$ changes. We use the CTEQ6L values $M_c = 1.3$ GeV and $M_b = 4.5$ GeV. We here use a NLO version of $\alpha_s(Q^2)$, with $\alpha_s(M_Z^2) = 0.118$, made continuous at $M_b$ and $M_c$, that was utilized in CTEQ6L (for details see Ref. [7]).

**FIG. 3:** Plots for LO CTEQ6L [7] gluon distributions $G(x, Q^2) = xg(x, Q^2)$ (upper plot) and $F_s(x, Q^2)$ distributions (lower plot) vs. Bjorken $x$. The curves are for $Q^2 = 10, 22, 90, 1200$ and $M_Z^2$ GeV$^2$, bottom to top. The (red) dots are our evolution results for LO $G(x, Q^2)$ from Eq. (31) and $F_s$ from Eq. (30) (converted to $x$-space) using the LO CTEQ6L values for $F_{s0}(x)$ and $G_0(x)$, where $Q^2_0 = 1.69$ GeV$^2$. The $x$ range in this Figure covers all of the published LO CTEQ6L $x$ data.

A. $G(x, Q^2)$ and $F_s(x, Q^2)$ for LO CTEQ6L

In Fig. 3 we show the Bjorken $x$-space results for LO $G(x, Q^2) = xg(x, Q^2)$ (upper figure) and LO $F_s(x, Q^2)$ (lower figure) vs. $x$, for 5 representative values of $Q^2$. The $x$-domain, $10^{-6} \leq x \leq 1$, is the complete region covered by the CTEQ group [7]. The curves are the published CTEQ6L [7] LO distributions. From bottom to top: the (red) curve is for $Q^2 = 10$ GeV$^2$; the (brown) dashed curve is for $Q^2 = 22$ GeV$^2$; the (blue) dot-dashed curve is for $Q^2 = 90$ GeV$^2$; the (black) dotted curve is for $Q^2 = 1200$ GeV$^2$; the (orange) curve is for $Q^2 = M_Z^2$. Since CTEQ6L [7] started evolution at $Q^2_0 = 1.69$ GeV$^2$, we used $F_{s0}$ and $G_0$ constructed from their values at $Q^2_0 = 1.69$ GeV$^2$ in Eq. (31)
and Eq. (30). The (red) dots are our results for LO \( G(x, Q^2) \) from Eq. (31) and \( F_s(x, Q^2) \) from Eq. (30) converted to \( x \)-space, using LO CTEQ6L values for \( F_{s0}(x) \) and \( G_0(x) \), evaluated using Mathematica [15].

For all \( Q^2 \) the agreement is excellent over the entire \( x \) region, with a fractional accuracy of about \( \pm 5 \times 10^{-4} \), (completely consistent with the 4 significant figures that are published)—for all \( F_s \) and \( G \) at the five virtualities that we evaluated—with a minor and numerically unimportant exception of the lowest \( x \) region of \( F_s(x, Q^2 = 22) \), where there was an offset of \( \approx 2 \times 10^{-3} \).

### B. Accuracy of CTEQ6L devolved distributions

In Fig. 3 all of the distributions were for evolutions of \( G \) and \( F_s \) from the CTEQ6L \( Q_0^2 = 1.69 \) GeV\(^2\) to larger \( Q^2 \). For another physics investigation, not relevant to this paper, we decided to compare LO starting distributions for MRST2008 and CTEQ6L at the MSTW2008 starting value of \( Q_0^2 = 1 \) GeV\(^2\). Using \( n_f = 3 \), we devolved \( G \) and \( F_s \) from the CTEQ6L starting values at \( Q_0^2 = 1.69 \) GeV\(^2\) down to \( Q^2 = 1 \) GeV\(^2\), the MSTW2008 starting value for \( Q_0^2 \).

The results of this devolution are compared to the published CTEQ6L values [1] in Fig. 4 for \( G \) (upper figure) and \( F_s \) (lower figure). In all cases, when we refer to “published CTEQ6L values”, we mean the results found on the Durham pdf generator web site; see footnote [17]. The solid (black) curves are for CTEQ6L and the (red) dots are from Eq. (31) and Eq. (30). In marked contrast to their evolution results, the CTEQ6L devolution results are numerically unstable, with \( F_s \) being wrong by \( \approx 12\% \) at \( x = 10^{-6} \). We also note that there are large disagreements with their devolved \( G(x) \) for small \( x \). Clearly, they have chosen to chop off their \( G \) distribution at small \( x \), i.e., to write \( G(x) = 0 \) for small \( x \), rather than allow it to become negative. The errors for both \( G \) and \( F_s \) become insignificant as \( x \) approaches 1. It is clear that CTEQ encounters major problems with the numerical stability of their published results for \( Q^2 < Q_0^2 \), whereas they are completely accurate for \( Q^2 > Q_0^2 \).

For comparison, we also show in Fig. 4 the published MSTW2008 starting distributions [8] \( G_0(x) \) and \( F_{s0}(x) \) at \( Q_0^2 = 1 \) GeV\(^2\), the dashed (blue) curves. We note that the LO gluon distributions of the two different collaborations, when evaluated at the same virtuality, \( Q^2 = 1 \) GeV\(^2\), bear little or no resemblance to each other, with the CTEQ6L gluon distribution going negative for \( x \lesssim 3 \times 10^{-5} \). Although both singlet structure functions \( F_s(x, Q^2 = 1) \) stay positive—as they must—Fig. 4 shows that there are also large differences between the two singlet structure functions at low \( x \).

### VI. OVERALL NUMERICAL ACCURACY OF ANALYTICAL DEVOLUTION AND EVOLUTION

As mentioned in Section VI.B we had devolved from \( Q_0^2 = 1.69 \) GeV\(^2\) to \( Q^2 = 1 \) GeV\(^2\), using the known CTEQ6L \( G_0(x) \) and \( F_{s0}(x) \) starting values. To estimate the overall accuracy of our entire numerical procedure, we took our devolved distributions \( G(x, Q^2 = 1) \) and \( F_s(x, Q^2 = 1) \) and used them as starting values so that we could again evolve back to \( Q^2 = 1.69 \) GeV\(^2\). Finally, we compared the evolved numerical results with the original \( F_{s0}(x) \) and \( G_0(x) \), the distributions that we started with at \( Q^2 = 1.69 \) GeV\(^2\). An outline of our entire numerical procedure is given in the Appendix.

In Fig. 5 we show the fractional accuracy of this “round-trip” comparison. The upper figure is for \( G \) and the lower figure is for \( F_s \). The (red) dots are the “round-trip” fractional accuracies at discrete \( x \)-values chosen to start and end this numerical exercise (corresponding to the transformed zeroes of the Chebyshev polynomials that we discuss in the Appendix). For the visual convenience of the reader, we have connected the dots.

Where either \( G \) and \( F_s \) is significantly large (\( x \lesssim 0.3 \)), we see that the “round-trip” error is \( \lesssim 4 \times 10^{-9} \), thus yielding an overall error estimate of \( \lesssim \pm 2 \times 10^{-9} \) for either evolution or devolution. Detailed causes for this error are discussed in the Appendix.

It is gratifying that the overall numerical uncertainty in our LO analytically decoupled solutions is small, thus furnishing us not only with a new accurate and fast calculation tool for exploring the effects of the shapes of different starting value distributions, but also with a diagnostic tool for easily determining the numerical calculational reliability of the already published parton distribution functions that are currently in major use by the high energy physics community.

### VII. CONCLUSIONS

In conclusion, we have constructed decoupled analytical solutions for \( F_s(x, Q^2) \) and \( G(x, Q^2) \) from the coupled LO DGLAP equations, yielding accurate numerical results for both evolution and devolution of \( O(10^{-9}) \)—a fast tool to study the dependence on the shape of the starting distributions \( F_{s0}(x) \) and \( G_0(x) \), the boundary conditions at the
starting value $Q_0^2$. Similar procedures can be used for non-singlet distributions, allowing one to obtain analytic LO solutions for individual quark distributions, as well as for the gluon distribution; thus avoiding the necessity for purely numerical solutions of the coupled DGLAP equations on a giant two-dimensional grid in $(x, Q^2)$ space. In essence, using a program such as Mathematica [15], we can now define a parton distribution function for each quark and gluon and—after inputting the desired $x$ and $Q^2$—evaluate it accurately and rapidly (for a fast Mathematica program calculating LO $F_s(x, Q^2)$ and $G(x, Q^2)$, see the Appendix).

We have also used our analytic solutions coupled with the MSTW2008 initial starting functions [6] as a new and powerful diagnostic tool to study the numerical accuracy (the computational accuracy of their evolution code) of the LO MSTW2008 published distributions [6]. For the small $x$-region, $x \lesssim 10^{-4}$, we discovered a pattern of significant numerical (computational) errors for both $F_s$ and $G$, ranging up to $\approx 12\%$ at the smallest $x$ values in the published MSTW2008 results [6], true for all $Q^2$.

Applying the same new tools to CTEQ6L, we found no errors (to their accuracy of 4 significant figures) in either $F_s$ or $G$ values when they did evolution from $Q_0^2 = 1.69$ GeV$^2$ to higher $Q^2$ values, but significant errors—increasing with decreasing $x$—when they did devolution to smaller $Q^2$. In the future, we intend to evaluate $F_{s0}(x)$ and $G_0(x)$ in both LO and NLO, from a fit to small $x$ experimental data for the structure function $F_{2p}(x, Q^2)$, in order to obtain (analytically) accurate values of $G(x, Q^2)$ directly tied to experiment, which are needed for the interpretation of experiments at the LHC.
FIG. 5: Fractional accuracy plots for our LO gluon distributions $G(x,Q^2) = xg(x,Q^2)$ (upper figure) from Eq. (31) and $F_s(x,Q^2)$ distributions (lower figure) from Eq. (30). These accuracy estimates resulted from devolution from $Q_0^2 = 1.69 \text{ GeV}^2$ to $Q^2 = 1 \text{ GeV}^2$, then using these results for evolution back to $Q^2 = 1.69 \text{ GeV}^2$. The fractional value error estimates result from comparing the original values with the devolved-evolved ones.

Appendix A

We outline here the actual calculation procedures necessary for fast and accurate numerical evaluations of Eq. (30) and Eq. (31). These calculations, although robust, require delicate choices as to the numerical techniques used in evaluating Eq. (30) and Eq. (31).

As shown in Ref. [4], if the function $g(s)$ goes to 0 at $\infty$ more rapidly than $1/s$, then we can accurately approximate its inverse Laplace transform $G(v)$ by

$$G(v) \approx -\frac{2}{v} \sum_{i=1}^{N} \text{Re}[\omega_i g(\alpha_i/v)], \quad (A1)$$

where $2N$ is the order of the approximation, $\omega_i$ and $\alpha_i$, $i = 1, 2, \ldots, 2N$, are known complex numbers for a given $2N$, occurring in complex conjugate pairs. The actual numerical evaluation of Eq. (A1) can be quite unstable if one doesn’t utilize arbitrary accuracy arithmetic as discussed in Ref. [4], since the weight functions $\omega_i$ become exceedingly large,
even for modest $2N$, and oscillate in sign\(^3\). The use of Mathematica (or similar programs, which also carry out arithmetical operations to arbitrary accuracy) makes this requirement easy to satisfy.

As shown in Ref.\(^4\), the inverse Laplace transform approximation to $G(v)$ is exact if $G(v)$ is a polynomial in $v$ of order $4N-1$ or less. For our purposes here, $G(v)$ in Eq.\(^A\(1\)) is either the $F_0(s, Q^2)$ or the $G(v, Q^2)$ on the l.h.s. of Eq.\(^A\(3\)) or Eq.\(^A\(1\)), whereas $g(s)$ in Eq.\(^A\(1\)) is the surrogate for either $k_{ff}(s, \tau)f_0(s) + k_{fg}(s, \tau)g_0(s)$ found in the r.h.s. of Eq.\(^A\(3\)) or $k_{gg}(s, \tau)g_0(s) + k_{gf}(s, \tau)f_0(s)$ found in the r.h.s. of Eq.\(^A\(1\)). Since we must evaluate $g(s)$ at complex values of $s$, this necessarily implies that we must evaluate $f_0(s)$ and $g_0(s)$—the Laplace transforms of $F_0(s)$ and $G_0(s)$, respectively—at complex values of $s$. As shown in Ref.\(^4\), to insure numerical accuracy we must be able to evaluate $g(s)$ in Eq.\(^A\(1\)) to arbitrary accuracy. Thus we must know the Laplace transforms $f_0(s)$ and $g_0(s)$ analytically and not just as numerical integrations of the form $\int_0^\infty F_0(s)e^{-sv}dv$. The $k$’s, the coefficient functions needed, are known analytically; the potential problem is with $f_0(s)$ and $g_0(s)$, the starting functions in Laplace space $s$.

The starting distributions functions normally used are not of the type that have analytic Laplace transforms. To get a sufficiently accurate numerical approximation to functions that do have analytic Laplace transforms is again a delicate numerical exercise. We found that we could do it sufficiently accurately by using an interpolating polynomial of order $n=49$. Its 50 coefficients were determined by evaluating the original function at 50 points, distributed as the zeroes of a $50^{th}$ order Chebyshev polynomial, found in the interval $(-1, +1)$ and then linearly transformed to $v$ space to lie in the interval $0 \leq v < 14$ ($1 \geq x > 0.83 \times 10^{-6}$). These points were chosen to try to minimize the maximum interpolation error. We note that even when using Mathematica, caution was needed in order to obtain sufficient numerical accuracy with a such a high order polynomial; it had to be evaluated using Horner’s method (see Section 10.14 of Ref.\(^1\)), since straight forward evaluation of such a high order polynomial will yield numerical nonsense.

Using $2N = 38$ in Eq.\(^A\(1\)) we would have an exact result if either $F_0(v, Q^2)$ in Eq.\(^A\(3\)) or $G(v, Q^2)$ in Eq.\(^A\(1\)) were a polynomial in $v$ of degree 75 or less; see Ref.\(^4\) for details. In actual practice, by comparing the results for the value of $2N = 38$ —the value we used for our numerical evaluations—with very much larger values of $2N$ that we used for estimates of the exact solutions, we found that the fractional accuracy of inversion for both $F_0(v, Q^2)$ and $G(v, Q^2)$ was $\approx 1 \times 10^{-11}$ for $v \geq 0.3$. Thus, numerical inversion of the Laplace transform in either Eq.\(^A\(3\)) or Eq.\(^A\(1\)) contributes essentially nothing to our overall error of about $\pm 2 \times 10^{-9}$, since it’s some 2 orders of magnitude smaller. We comment that the overall error is essentially completely due to our numerical approximation of the starting functions and not the subsequent Laplace transforms of them. Therefore, we could readily reduce this error by using more than 50 points in our numerical approximations of the starting distributions, but this would be at the expense of more computational time and was felt to be unnecessary.

A typical time for computing the full $x$ distribution of either $F_0(x)$ or $G(x)$ at an arbitrary $Q^2$—given the starting functions $F_0(x)$ and $G_0(x)$ at $Q^2_0$—was about 15 seconds, basically proportional to the number of points in $x$ used in the numerical approximations of the starting functions and to the number $2N$ used in the Laplace inversion routine. Thus, for most applications, we could easily reduce this time to several seconds, at the expense of some (perhaps unneeded) accuracy. The computations in this paper were made on a home PC, a Dell Model Studio XPS435MT, using an Intel 2.67 GHz 4 core i7 CPU, running 64 bit Windows Vista, and using Mathematica7\(^12\) in parallel mode.

For a very fast Mathematica\(^7\) (nb) program that accurately calculates all LO MSTW2008 parton distribution functions, as well as $F_2^T(x)$ and $F_2(x)$ for any $Q^2$—using the LO MSTW starting values\(^3\) for $F_0(x)$, $G(x)$ at $Q^2_0 = 1$ GeV$^2$—send an email request to mblock@northwestern.edu for MSTW.zip.
