Scattering of Solitons for Coupled Wave-Particle Equations

Running head: Soliton Scattering for Wave-Particle Eqs

Abstract

We establish a long time soliton asymptotics for a nonlinear system of wave equation coupled to a charged particle. The coupled system has a six dimensional manifold of soliton solutions. We show that in the large time approximation, any solution, with an initial state close to the solitary manifold, is a sum of a soliton and a dispersive wave which is a solution to the free wave equation. It is assumed that the charge density satisfies Wiener condition which is a version of Fermi Golden Rule, and that the momenta of the charge distribution vanish up to the fourth order. The proof is based on a development of the general strategy introduced by Buslaev and Perelman: symplectic projection in Hilbert space onto the solitary manifold, modulation equations for the parameters of the projection, and decay of the transversal component.

1 Introduction

Our paper concerns an old mathematical problem of nonlinear field-particle interaction. A charged particle radiates a field which acts on the particle etc. This self-action is probably responsible for some crucial features of the process: asymptotically uniform motion of the particle, increment of the particle’s mass etc. (see [38], Part I). The problem has many different appearances: for a classical particle coupled to a scalar or Maxwell field, for coupled Maxwell-Schrödinger or Maxwell-Dirac equations, for the corresponding second-quantized equations etc.

One of the main goals of mathematical investigation of this problem is studying soliton-type long time asymptotics and asymptotic stability of soliton solutions. The first results in this direction have been discovered for KdV equation and other complete integrable equations. For KdV equation, any solution with sufficiently smooth and rapidly decaying initial data converges to a finite sum of solitons moving to the right, and a dispersive wave moving to the left. A complete survey and proofs can be found in [12, 14].

For non-integrable equations, the long time convergence of the solution to a soliton part and dispersive wave was obtained first by Soffer and Weinstein in the context of $U(1)$-invariant Schrödinger equation with potential, [33, 34, 35]. The extension to translation invariant equations was obtained by Buslaev and Perelman [4, 5, 6, 7] for 1D Schrödinger equation, and by Miller, Pego and Weinstein for 1D modified KdV and RLW equations, [28, 29, 30]. Later the results were developed by Bambusi and Cuccagna [2, 8, 9, 10], and Martel and Merle [27].

In [4, 5, 6, 7] the long time convergence is obtained for translation invariant and $U(1)$-invariant nonlinear Schrödinger equation: for any finite-energy solution $\psi(x,t)$ with initial data close to a soliton $\psi_{v_0}(x-v_0t-a_0)e^{i\omega_0 t}$, the following asymptotics hold:

$$
\psi(x,t) = \psi_{\pm}(x - v_{\pm}t - a_{\pm})e^{i\omega_{\pm} t} + W_0(t)\psi_\pm + r_\pm(x,t), \ t \to \pm \infty.
$$

(1.1)

Here the first term of the right hand side is a soliton with parameters $v_{\pm}$, $a_{\pm}$, $\omega_{\pm}$ close to $v_0$, $a_0$, $\omega_0$, the function $W_0(t)\psi_\pm$ is a dispersive wave which is a solution to the free Schrödinger equation, and the remainder $r_\pm(x,t)$ converges to zero in the global $L^2$-norm.

In the present paper we consider a scalar real-valued wave field $\psi(x)$ in $\mathbb{R}^3$, coupled to a relativistic particle with position $q$ and momentum $p$, governed by

$$
\dot{\psi}(x,t) = \pi(x,t), \ \ \ \pi(x,t) = \Delta \psi(x,t) - \rho(x - q(t)), \ x \in \mathbb{R}^3,
$$

$$
\dot{q}(t) = p(t)/\sqrt{1+p^2}, \ \ \dot{p}(t) = \int \psi(x,t) \nabla \rho(x - q(t)) dx.
$$

(1.2)

This is a Hamilton system with the Hamilton functional

$$
\mathcal{H}(\psi, \pi, q, p) = \frac{1}{2} \int \left( |\pi(x)|^2 + |\nabla \psi(x)|^2 \right) dx + \int \psi(x) \rho(x - q) dx + \sqrt{1+p^2}.
$$

(1.3)

The first two equations for the fields are equivalent to the wave equation with the source $\rho(x - q)$. We have set the mechanical mass of the particle and the speed of wave propagation equal to one. The case of the point particle corresponds to $\rho(x) = \delta(x)$ and then the interaction term in the Hamiltonian is simply $\psi(q)$. However, in this case the Hamiltonian is unbounded from below which leads to the ill-posedness of the problem, that is also known as ultraviolet divergence. Therefore we smooth the coupling by the function $\rho(x)$ following the “extended electron” strategy proposed by M. Abraham for the Maxwell field. In analogy to the Maxwell-Lorentz equations we call $\rho$ the “charge distribution”. Finally, the form of the last two equations in (1.2) is determined by the choice of the relativistic kinetic energy $\sqrt{1+p^2}$ in (1.3).

Let us write the system (1.2) as

$$
\dot{Y}(t) = F(Y(t)), \ t \in \mathbb{R},
$$

(4.1)

where $Y(t) := (\psi(x,t), \pi(x,t), q(t), p(t))$. The system (1.2) is translation-invariant and admits soliton solutions

$$
Y_{a,v}(t) = (\psi_v(x - vt - a), \pi_v(x - vt - a), vt + a, p_v), \ \ \ p_v = v/\sqrt{1-v^2}
$$

(1.5)

for all $a, v \in \mathbb{R}^3$ with $|v| < 1$ (see (2.8) to (2.11) below). The states $S_{a,v} := Y_{a,v}(0)$ form the solitary manifold

$$
S := \{ S_{a,v} : a, v \in \mathbb{R}^3, |v| < 1 \}.
$$

(1.6)
Our main result (announced in [20]) is the soliton asymptotics of type (1.11),

\[ (\psi(x,t), \pi(x,t)) \sim (\psi_{v_{\pm}}(x-v_{\pm}t-a_{\pm}), \pi_{v_{\pm}}(x-v_{\pm}t-a_{\pm})) + W_0(t)\Psi_{\pm}, \quad t \to \pm \infty, \]  

(1.7)

for solutions to (1.2) with initial data close to the solitary manifold \( S \). Here \( W_0(t) \) is the dynamical group of the free wave equation, \( \Psi_{\pm} \) are the corresponding asymptotic scattering states, and the remainder converges to zero \textit{in the global energy norm}, i.e. in the norm of the Sobolev space \( \dot{H}^1(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3) \), see Section 2. For the particle’s trajectory we prove that

\[ \dot{q}(t) \to v_{\pm}, \quad q(t) \sim v_{\pm}t + a_{\pm}, \quad t \to \pm \infty. \]  

(1.8)

The results are established under the following conditions on the charge distribution: \( \rho \) is a real-valued function of the Sobolev class \( H^2(\mathbb{R}^3) \), compactly supported, and spherically symmetric, i.e.

\[ \rho, \nabla \rho, \nabla^2 \rho \in L^2(\mathbb{R}^3), \quad \rho(x) = 0 \text{ for } |x| \geq R_\rho, \quad \rho(x) = \rho_1(|x|). \]  

(1.9)

We require that all “nonzero modes” of the wave field are coupled to the particle. This is formalized by the Wiener condition

\[ \dot{\rho}(k) = (2\pi)^{-3/2} \int e^{ikx} \rho(x) dx \neq 0 \quad \text{for all } k \in \mathbb{R}^3 \setminus \{0\}. \]  

(1.10)

It is the nonlinear Fermi Golden Rule for our model: the coupling term \( \rho(x - q) \) is not orthogonal to the eigenfunctions \( e^{ikx} \) of the continuous spectrum of the linear part of the equation (cf. [21, 26, 10, 11, 32, 36]). Note that the Wiener condition is close to the linear version of the FGR [31, pp. 67-68]. As we will see, the Wiener condition (1.10) is very essential for our asymptotic analysis. Generic examples of the coupling function \( \rho \) satisfying (1.9) and (1.10) are given in [22]. In particular, the Wiener condition allows us to identify the discrete spectral subspace corresponding to the spectral point \( \lambda = 0 \) of the linearized system. Thus, we do not impose any implicit spectral conditions for the linearized system. Further, we will assume that \( \rho(k) \) has a fifth order zero at the point \( k = 0 \), i.e.

\[ \dot{\rho}^{(\alpha)}(0) = 0 \quad \text{for all multiindices } \alpha \text{ with } |\alpha| \leq 4. \]  

(1.11)

Equivalently, the following momenta vanish:

\[ \int x^\alpha \rho(x) dx = 0, \quad |\alpha| \leq 4, \]  

(1.12)

in particular, the total charge of the particle is zero (neutrality condition). It is easy to obtain an example of \( \rho \) satisfying both (1.10) and (1.11). Indeed, take a \( \rho_2 \) satisfying the Wiener condition (1.10). Then \( \rho = \Delta^3 \rho_2 \) satisfies both (1.10) and (1.11).

The system (1.2) describes the charged particle interacting with its “own” scalar field. The asymptotics (1.7)-(1.8) mean asymptotic stability of uniform motion, i.e. “the law of inertia”. The stability is caused by “radiative damping”, i.e. radiation of energy to infinity appearing analytically as a local energy decay for solutions to the linearized equation provided by the Wiener condition (1.9). The radiative damping was suggested first by M. Abraham in 1905 in the context of Classical Electrodynamics, [1]. However, the asymptotics (1.7)-(1.8) are not proved yet for the Klein-Gordon field, Maxwell field, and spinning charge subject to Maxwell field respectively. Our result is a model of this situation though the relativistic case is still an open problem.

Let us briefly comment on earlier results. In the case of weak coupling, i.e. \( \|\rho\|_{L^2} \ll 1 \), scattering behavior of type (1.7) for the system (1.2) is established in [17] for all finite energy solutions. In [15, 16, 18] the result was extended to the cases of Klein-Gordon field, Maxwell field, and spinning charge subject to Maxwell field respectively. The results under the Wiener condition are not established yet.

The system (1.2) under the Wiener condition was considered in [22, 23, 21]. In [22] the convergence to stationary states is proved for all finite energy solutions: in particular, the relaxation of acceleration \( \ddot{q} \to 0 \) as \( t \to 0 \) holds. In [23] the soliton-type asymptotics for the fields is established for all finite energy solutions. In [21] the effective dynamics under the slowly varying potential is constructed for solutions sufficiently close to the solitary manifold. However, the asymptotics (1.7) and (1.8) are not established in [22, 23, 21].
A long time asymptotics of type \((1.7)\) appears also in nonlinear wave equations, like the KDV \([12, 14]\) and the \(U(1)\)-invariant nonlinear Schrödinger equation \([4, 5, 6, 7, 29, 30, 33, 34, 35]\). In these equations there are no particle degrees of freedom and the solitons \((1.5)\) correspond to the solitary wave solutions travelling at constant velocity.

Our approach relies on and further develops the general strategy introduced in the cited papers in the context of the \(U(1)\)-invariant Schrödinger equation. The approach uses i) symplectic projection of the dynamics in the Hilbert phase space onto the symplectic orthogonal directions to the solitary manifold to kill the runaway secular solutions, ii) the modulation equations for the motion along the solitary manifold, and iii) freezing of the dynamics in the nonautonomous linearized equation. See more details in Introduction \([19]\) where the general strategy has been developed for the case of the Klein-Gordon equation. The case of wave equation \((1.2)\) differs significantly from the Klein-Gordon case because of i) slow Coulombic decay of the solitons, and ii) presence of the embedded eigenvalue in the continuous spectrum of the linearized equation (see the comments below).

Developing the general strategy for equations \((1.2)\), we obtain our main result in Sections 3-6 and 11-15 of the paper. The main novelty in our case is thorough establishing the appropriate decay of the linearized dynamics in Sections 7-10 and Appendices A, B:

I. We do not postulate any spectral properties of the linearized equation, calculating all the properties from the Wiener condition \((1.10)\). Namely, we show that i) the full zero spectral space of the linearized equation is spanned by the tangent vectors, and moreover, ii) there are no others (nonzero) discrete eigenvalues (see Lemmas \([9.5, 9.6]\) and Proposition \([8.1]\)).

II. Using these spectral properties, we prove that the linearized equation is stable in the symplectic orthogonal complement to the tangent space \(T_S\) spanned by the tangent vectors \(\partial_a S_{α, v}\) and \(\partial v S_{α, v}\), \(j = 1, 2, 3\). We exactly calculate in Lemma \([9.6]\) the corresponding symplectic orthogonality conditions for initial data of the linearized dynamics.

III. One of main peculiarities of the wave equations \((1.2)\) is the presence of embedded eigenvalue \(λ = 0\) in the continuous spectrum \(σ_c = \mathbb{R}\) of the linearized equation. This situation never happens in all previous works on the asymptotic stability of the solitary waves for the Schrödinger and Klein-Gordon equations. Thus, the symplectic orthogonality condition is imposed now at the interior point of the continuous spectrum in contrast to all previous works in the field. Respectively, the integrand at this point in the spectral representation of the solution is not smooth even if the symplectic orthogonality condition holds. Hence, the integration by parts in this spectral representation as in the case of the Schrödinger and Klein-Gordon equation, is impossible. For the proof of the decay in this new situation, we transform the spectral representation in the proofs of Propositions \([9.2, 9.4]\) and develop new more subtle technique of convolutions.

Our paper is organized as follows. In Section 2, we formulate the main result. In Section 3, we introduce the symplectic projection onto the solitary manifold. The linearized equation is defined and studied in Sections 4-5. In Section 6, we split the dynamics in two components: along the solitary manifold, and in transversal directions, and we justify the slow motion of the longitudinal component. Sections 7-10 concern the time decay of the transversal component in the linearized dynamics. The time decay of the transversal component in the nonlinear dynamics is established in Sections 11-14. In Section 15 we prove the main result. In Appendices A, B we collect routine calculations.

Acknowledgements The authors thank V. Buslaev for detailed and numerous lectures on his results, H. Spohn and E. Kopylova for fruitful discussions.

2 Main Results

2.1 Existence of Dynamics

To formulate our results precisely, we need some definitions. We introduce a suitable phase space for the Cauchy problem corresponding to \((1.2)\). Let \(L^2\) be the real Hilbert space \(L^2(\mathbb{R}^3)\) with the scalar product \(\langle \cdot, \cdot \rangle\) and the corresponding norm \(\| \cdot \|\), and let \(\hat{H}^1\) be the completion of the real space \(C_0^\infty(\mathbb{R}^3)\) with the norm \(\| \nabla \psi(x) \|\). Equivalently, using Sobolev embedding theorem, \(\hat{H}^1 = \{ \psi(x) \in L^6(\mathbb{R}^3) : \| \nabla \psi(x) \| \in L^2 \}\). Let us introduce the weighted Sobolev spaces \(L^2_α\) and \(H^1_α\) with the norms \(\| \psi \|_α = \| (1 + |x|)^α \psi \|\) and \(\| \psi \|_{1, α} = \| \psi \|_α + \| \nabla \psi \|_α\) respectively.
Definition 2.1 i) $\mathcal{E}$ is the Hilbert space $\hat{H}^1 \oplus L^2 \oplus \mathbb{R}^3 \oplus \mathbb{R}^3$ with the finite norm
\[\| Y \|_\mathcal{E} = |\nabla \psi| + |\pi| + |q| + |p| \text{ for } Y = (\psi, \pi, q, p).\]

ii) $\mathcal{E}_\alpha$ is the space $H^1_\alpha \oplus L^2_\alpha \oplus \mathbb{R}^3 \oplus \mathbb{R}^3$ with the norm
\[\| Y \|_{\mathcal{E}_\alpha} = \| \psi \|_{1,\alpha} + |\pi|_{\alpha+1} + |q| + |p|.
\]

iii) $\mathcal{F}$ is the space $\hat{H}^1 \oplus L^2$ of fields $F = (\psi, \pi)$ with the finite norm
\[\| F \|_\mathcal{F} = |\nabla \psi| + |\pi|.
\]

iv) $\mathcal{F}_\alpha$ is the space $H^1_\alpha \oplus L^2_\alpha$ with the norm
\[\| F \|_{\mathcal{F}_\alpha} = \| \psi \|_{1,\alpha} + |\pi|_{\alpha+1}
\]

Note that $\hat{H}^1$ is not contained in $L^2$ and for instance $|\psi_y| = \infty$ if the neutrality condition is not imposed, see (2.11) below. However, $\mathcal{E}$ is the space of finite energy states (i.e. $\mathcal{H}(Y) < \infty$ for $Y \in \mathcal{E}$) due to the following estimates which are valid for an arbitrary smooth $\psi(x)$ vanishing at infinity
\[- \frac{1}{8\pi} \int dx \int dy \frac{\rho(x)\rho(y)}{|x-y|} = \frac{1}{2} \langle \rho, \Delta^{-1} \rho \rangle \leq \frac{1}{2} \| \nabla \psi \|^2 + \langle \psi(x), \rho(x-q) \rangle \leq |\nabla \psi|^2 - \frac{1}{2} \langle \rho, \Delta^{-1} \rho \rangle.
\]

The Hamilton functional $\mathcal{H}$ is continuous in the space $\mathcal{E}$, and the lower bound in (2.4) implies that the energy (1.3) is bounded from below. Note that the latter is not true if $\rho$ is delta-function.

We consider the Cauchy problem for the Hamilton system (1.2) which we write as
\[\dot{Y}(t) = F(Y(t)), \quad t \in \mathbb{R}; \quad Y(0) = Y_0.
\]

Here $Y(t) = (\psi(t), \pi(t), q(t), p(t))$, $Y_0 = (\psi_0, \pi_0, q_0, p_0)$, and all derivatives are understood in the sense of distributions.

Proposition 2.2 Let (1.4) hold. Then
(i) For every $Y_0 \in \mathcal{E}$, the Cauchy problem (2.5) has a unique solution $Y(t) \in C(\mathbb{R}, \mathcal{E})$.
(ii) For every $t \in \mathbb{R}$, the map $U(t) : Y_0 \mapsto Y(t)$ is continuous in $\mathcal{E}$.
(iii) The energy is conserved, i.e.
\[\mathcal{H}(Y(t)) = \mathcal{H}(Y_0), \quad t \in \mathbb{R},
\]
and the velocity is bounded:
\[|\dot{\psi}(t)| \leq \tilde{\gamma} < 1, \quad t \in \mathbb{R},
\]
with some $\tilde{\gamma}$ which depends on $Y_0$.

2.2 Solitary Manifold and Main Result

Let us compute the solitons (1.5). The substitution to (1.2) gives the following stationary equations,
\[-v \cdot \nabla \psi_v(y) = \pi_v(y), \quad -v \cdot \nabla \pi_v(y) = \Delta \psi_v(y) - \rho(y)
\]
\[v = \frac{p_v}{\sqrt{1 + p_v^2}}, \quad 0 = -\int \nabla \psi_v(y) \rho(y) dy
\]

Then the first two equations imply
\[\Lambda_v \psi_v(y) := (-\Delta + (v \cdot \nabla)^2) \psi_v(y) = -\rho(y), \quad y \in \mathbb{R}^3.
\]

For $|v| < 1$ the equation (2.9) defines a unique function $\psi_v \in \hat{H}^1(\mathbb{R}^3)$. If $v$ is given and $|v| < 1$, then $p_v$ can be found from the third equation of (2.5). Further, functions $\rho$ and $\psi_v$ are even due to (1.9). Thus, $\nabla \psi_v$ is odd
and the last equation of (2.8) holds. Hence, the soliton solution (1.5) exists and is defined uniquely for any couple \((a,v)\) with \(|v| < 1\).

The soliton can be computed by the Fourier transform \(\hat{\psi}(k) := (2\pi)^{-3/2} \int e^{ikx} \psi(x) dx:\)

\[
\hat{\psi}_v(k) = \frac{\hat{\rho}(k)}{k^2 - (kv)^2}, \quad \hat{\pi}_v(k) = \frac{ikv\hat{\rho}(k)}{k^2 - (kv)^2}
\] (2.10)

In the coordinate space

\[
\psi_v(x) = -\frac{1}{4\pi} \int \frac{\rho(y)d^3y}{|\gamma(y-x)|| + (y-x)_\perp|}, \quad \pi_v(x) = -v \cdot \nabla \psi_v(x), \quad p_v = \gamma v.
\] (2.11)

Here we set \(\gamma = 1/\sqrt{1-v^2}\) and \(x = x_\parallel + x_\perp\), where \(x_\parallel\|v\) and \(x_\perp\perp v\) for \(x \in \mathbb{R}^3\). From the condition (1.12) it follows that

\[
\psi_v(y) \sim |y|^{-6}, \quad \pi_v(y) \sim |y|^{-7} \text{ as } |y| \to \infty
\]

and thus,

\[
\psi_v \in H^1_\alpha, \quad \alpha < 9/2; \quad \pi_v \in L^2_\alpha, \quad \alpha < 11/2.
\] (2.12)

**Definition 2.3** A soliton state is \(S(\sigma) := (\psi_v(x-b), \pi_v(x-b), b, p_v)\), where \(\sigma := (b,v)\) with \(b \in \mathbb{R}^3\) and \(|v| < 1\).

By (2.12) for the soliton states we have

\[
S(\sigma) \in \mathcal{E}_\alpha, \quad \alpha < \frac{9}{2}.
\] (2.13)

Obviously, the soliton solution (1.5) admits the representation \(Y_{a,v}(t) = S(\sigma(t))\), where

\[
\sigma(t) = (b(t), v(t)) = (vt + a, v).
\] (2.14)

**Definition 2.4** The solitary manifold is the set \(\mathcal{S} := \{S(\sigma) : b \in \mathbb{R}^3, |v| < 1\}\).

The main result of our paper is the following theorem.

**Theorem 2.5** Let (1.1), the Wiener condition (1.10), and the condition (1.11) hold. Let \(0 < \delta < 1/2\), set \(\beta := 4 + \delta\). Consider the solution \(Y(t)\) to the Cauchy problem (2.5) with the initial state \(Y_0\) which is sufficiently close to the solitary manifold:

\[
Y_0 = S(\sigma_0) + Z_0, \quad d_\beta := \|Z_0\|_\beta \ll 1.
\] (2.15)

Then the asymptotics hold for \(t \to \pm \infty\),

\[
\dot{q}(t) = v_\pm + \mathcal{O}(|t|^{-1-\delta}), \quad q(t) = v_\pm t + a_\pm + \mathcal{O}(|t|^{-2\delta}),
\]

\[
(\psi(x,t), \pi(x,t)) = (\psi_{v_\pm}(x - v_\pm t - a_\pm), \pi_{v_\pm}(x - v_\pm t - a_\pm)) + W_0(t) \Psi_\pm + r_\pm(x,t)
\] (2.17)

with

\[
\|r_\pm(t)\|_F = \mathcal{O}(|t|^{-\delta}).
\] (2.18)

It suffices to prove the asymptotics (2.10), (2.17) for \(t \to +\infty\) since the system (1.2) is time reversible.
3 Symplectic Projection

3.1 Symplectic Structure and Hamilton Form

The system (1.2) reads as the Hamilton system

$$\dot{Y} = J \mathcal{D}H(Y), \quad J := \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & I_3 \\ 0 & 0 & -I_3 & 0 \end{pmatrix}, \quad Y = (\psi, \pi, q, p) \in \mathcal{E},$$

where \( \mathcal{D}H \) is the Fréchet derivative of the Hamilton functional (1.3), \( I_3 \) is the \( 3 \times 3 \) identity matrix. Let us identify the tangent space to \( E \) where

\[ \mathcal{D}H \mid_{Y} (v) = \int_{\mathcal{E}} d\psi(x) \wedge d\pi(x) dx + dq \wedge dp, \]

i.e.

$$\Omega(Y_1, Y_2) = \langle Y_1, JY_2 \rangle, \quad Y_1, Y_2 \in \mathcal{E},$$

where

$$\langle Y_1, Y_2 \rangle := \langle \psi_1, \psi_2 \rangle + \langle \pi_1, \pi_2 \rangle + q_1 q_2 + p_1 p_2$$

and \( \langle \psi_1, \psi_2 \rangle \) stands for the scalar product \( \int \psi_1(x) \psi_2(x) dx \) or its different extensions.

**Definition 3.1**

i) \( Y_1 \perp Y_2 \) means that \( Y_1 \) is symplectic orthogonal to \( Y_2 \), i.e. \( \Omega(Y_1, Y_2) = 0 \).

ii) A projection operator \( P : \mathcal{E} \to \mathcal{E} \) is called symplectic orthogonal if \( Y_1 \perp Y_2 \) for \( Y_1 \in \text{Ker } P \) and \( Y_2 \in \text{Im } P \).

3.2 Symplectic Projection onto Solitary Manifold

From now on we suppose that the condition (1.11) is satisfied. Let us consider the tangent space \( T \sigma S \) to the manifold \( S \) at a point \( S(\sigma) \), where \( \sigma = (b, v) \). The vectors \( \tau_j := \partial_\sigma S(\sigma) \), where \( \partial_\sigma := \partial_{b_j} \) and \( \partial_{\sigma_{3+j}} := \partial_{v_j} \)

with \( j = 1, 2, 3 \), form a basis in \( T\sigma S \). In detail,

\[
\begin{align*}
\tau_j &= \tau_j(v) := \partial_{b_j} S(\sigma) = \begin{pmatrix} \partial_1 \psi_j(y) & \partial_2 \pi_j(y) & e_j & 0 \end{pmatrix} \\
\tau_{3+j} &= \tau_{3+j}(v) := \partial_{v_j} S(\sigma) = \begin{pmatrix} \partial_1 \psi_j(v_j) & \partial_2 \pi_j(v_j) & 0 & \partial_3 e_j \end{pmatrix}
\end{align*}
\]

where \( y := x - b \) is the “coordinate in the moving frame”, \( e_1 = (1, 0, 0) \) etc.

By (2.12) for the tangent vectors we have

$$\tau_j(v) \in \mathcal{E}_\alpha, \quad \alpha < \frac{9}{2}, \quad j = 1, \ldots, 6.$$

**Lemma 3.2**
The matrix with the elements \( \Omega(\tau_j(v), \tau_j(v)) \) is non-degenerate for \( |v| < 1 \).

The proof is made by a straightforward computation, see [19], Lemma 3.2 for the case \( m = 0 \) (note that the left hand side of the identity [19 (A.8)]) is well defined by the condition (1.11).

Now we show that in a small neighborhood of the soliton manifold \( S \) a “symplectic orthogonal projection” onto \( S \) is well defined. Let us introduce the translations \( T_a : (\psi(x), \pi(x), q, p) \mapsto (\psi(x - a), \pi(x - a), q + a, p) \), \( a \in \mathbb{R}^3 \). Note that the manifold \( S \) is invariant with respect to the translations.

**Definition 3.3**
Let us denote by \( \nu(Y) := p/\sqrt{1 + p^2} \) where \( p \in \mathbb{R}^3 \) is the last component of the vector \( Y \).

**Lemma 3.4**
Let (1.9) hold, \( \alpha > -9/2 \) and \( \overline{v} < 1 \). Then

i) there exists a neighborhood \( \mathcal{O}_\alpha(S) \) of \( S \) in \( \mathcal{E}_\alpha \) and a map \( \Pi : \mathcal{O}_\alpha(S) \to S \) such that \( \Pi \) is uniformly continuous on \( \mathcal{O}_\alpha(S) \) \( \cap \{Y \in \mathcal{E}_\alpha : \nu(Y) \leq \overline{v}\} \) in the metric of \( \mathcal{E}_\alpha \).

\[
\Pi Y = Y \ \text{for } Y \in S, \quad \text{and } \quad Y - S \upharpoonright T \sigma S, \quad \text{where } S = \Pi Y.
\]

ii) \( \mathcal{O}_\alpha(S) \) is invariant with respect to the translations \( T_a \), and

\[
\Pi T_a Y = T_a \Pi Y, \quad \text{for } Y \in \mathcal{O}_\alpha(S) \text{ and } a \in \mathbb{R}^3.
\]

iii) For any \( \overline{v} < 1 \) there exists a \( \tilde{v} < 1 \) such that \( |\nu(\Pi Y)| < \tilde{v} \) when \( |\nu(Y)| < \overline{v} \).

iv) For any \( \tilde{v} < 1 \) there exists an \( r_\alpha(\tilde{v}) \) s.t. \( S(\sigma) + Z \in \mathcal{O}_\alpha(S) \) if \( |\nu(S(\sigma))| < \tilde{v} \) and \( \|Z\|_\alpha < r_\alpha(\tilde{v}) \).
The proof is similar to that of [19 Lemma 3.4].

We will call $\Pi$ the symplectic orthogonal projection onto $S$. 

**Corollary 3.5** [19, Corollary 3.5]. The condition (2.13) implies that $Y_0 = \tilde{S} + \tilde{Z}_0$ where $\tilde{S} = \Pi Y_0$, and

$$\|\tilde{Z}_0\|_\beta \ll 1.$$  \hfill (3.7)

## 4 Linearization on the Solitary Manifold

Let us consider a solution to the system (1.2), and split it as the sum

$$Y(t) = S(\sigma(t)) + Z(t),$$  \hfill (4.1)

where $\sigma(t) = (b(t), v(t)) \in \mathbb{R}^3 \times \{|v| < 1\}$ is an arbitrary smooth function of $t \in \mathbb{R}$. In detail, denote $Y = (\psi, \pi, q, p)$ and $Z = (\Psi, \Pi, Q, P)$. Then (4.1) means that

$$\begin{align*}
\psi(x, t) &= \psi_{v(t)}(x - b(t)) + \Psi(x - b(t), t), \quad q(t) = b(t) + Q(t) \\
\pi(x, t) &= \pi_{v(t)}(x - b(t)) + \Pi(x - b(t), t), \quad p(t) = p_{v(t)} + P(t)
\end{align*}$$  \hfill (4.2)

Let us substitute (4.2) to (1.2), and linearize the equations in $Z$. Later we will choose $S(\sigma(t)) = \Pi Y(t)$, i.e. $Z(t)$ is symplectic orthogonal to $T_{S(\sigma(t))}S$. However, this orthogonality condition is not needed for the formal process of linearization. The orthogonality condition will be important in Section 6, where we derive “modulation equations” for the parameters $\sigma(t)$.

Let us proceed to linearization. Setting $y = x - b(t)$ which is the coordinate in the moving frame, we obtain from (4.2) and (1.2) that

$$\begin{align*}
\dot{\psi} &= \dot{b} \cdot \nabla \psi_{v(t)}(y) - \dot{b} \cdot \nabla \psi_{v(t)}(y) + \psi(y, t) - \dot{b} \cdot \nabla \Psi(y, t) = \pi_{v(t)}(y) + \Pi(y, t) \\
\dot{\pi} &= \dot{b} \cdot \nabla \pi_{v(t)}(y) - \dot{b} \cdot \nabla \pi_{v(t)}(y) + \dot{\Pi}(y, t) - \dot{b} \cdot \nabla \Pi(y, t) \\
&= \Delta \psi_{v(t)}(y) + \Delta \Psi(y, t) - \rho(y - Q) \\
\dot{q} &= \dot{b} + \dot{Q} = \frac{p_{v} + P}{\sqrt{1 + (p_{v} + P)^2}} \\
\dot{p} &= \dot{b} \cdot \nabla \pi_{v} p_{v(t)} + \dot{P} = -\langle \nabla (\psi_{v(t)}(y)) + \Psi(y, t), \rho(y - Q) \rangle
\end{align*}$$  \hfill (4.3)

The equations are linear in $\Psi$ and $\Pi$, hence it remains to extract linear terms in $Q$ and $P$. Within this section, we estimate the remainders in the norms of the space $\mathcal{E}_\alpha$ with an arbitrary $\alpha > 0$.

First note that $\rho(y - Q) = \rho(y) - Q \cdot \nabla \rho(y) - N_2(Q)$, where $-N_2(Q) = \rho(y - Q) - \rho(y) + Q \cdot \nabla \rho(y)$; for $N_2(Q)$ the bound holds,

$$|N_2(Q)|_{\alpha} \leq C(Q)Q^2$$  \hfill (4.4)

uniformly in $|Q| \leq \overline{Q}$ for any fixed $\overline{Q}$. Second, the Taylor expansion gives

$$\frac{p_{v} + P}{\sqrt{1 + (p_{v} + P)^2}} = v + \nu(P - v(v \cdot P)) + N_3(v, P),$$

where $\nu = \nu_v := (1 + p_v^2)^{-1/2} = \sqrt{1 - v^2}$, and

$$|N_3(v, P)| \leq C(\overline{v})P^2$$  \hfill (4.5)

uniformly in $v$ with $|v| \leq \overline{v} < 1$. Using the equations (2.13), we obtain from (4.3) the following equations for the components of the vector $Z(t)$:

$$\begin{align*}
\dot{\Psi}(y, t) &= \Pi(y, t) + \dot{b} \cdot \nabla \Psi(y, t) + (\dot{b} - v) \cdot \nabla \psi_{v}(y) - \dot{v} \cdot \nabla \psi_{v}(y) \\
\dot{\Pi}(y, t) &= \Delta \Psi(y, t) + \dot{b} \cdot \nabla \Pi(y, t) + \Psi(\rho(y) + Q \cdot \nabla \rho(y)) + \dot{b} - v \cdot \nabla \pi_{v}(y) - \dot{v} \cdot \nabla \pi_{v}(y) + N_2 \\
\dot{Q}(t) &= \nu_v (I_3 - v \otimes v) P + (v - \dot{b}) + N_3 \\
\dot{P}(t) &= \langle \Psi(y, t), \nabla \rho(y) \rangle + \langle \nabla \psi_{v}(y), Q \cdot \nabla \rho(y) \rangle - \dot{v} \cdot \nabla \pi_{v} p_{v} + N_4(v, Z)
\end{align*}$$  \hfill (4.6)
where \( N_4(v, Z) = \langle \nabla \psi_v, N_2(Q) \rangle + \langle \nabla \Psi, Q \cdot \nabla \rho \rangle + \langle \nabla \Psi, N_2(Q) \rangle \). Clearly, \( N_4(v, Z) \) satisfies the following estimate

\[
|N_4(v, Z)| \leq C_{\beta}(\rho, \tilde{v}, \overline{Q}) [Q^2 + \|\Psi\|_{-\alpha} |Q|], \tag{4.7}
\]

uniformly in \( v, Q \) with \( |v| \leq \tilde{v} \) and \( |Q| \leq \overline{Q} \). We can write the equations (4.6) as

\[
\dot{Z}(t) = A(t)Z(t) + T(t) + N(t), \quad t \in \mathbb{R}. \tag{4.8}
\]

Here the operator \( A(t) \) depends on \( \sigma(t) = (b(t), v(t)) \). We will use the parameters \( v = v(t) \) and \( w := \dot{b}(t) \). Then \( A(t) \) can be written in the form

\[
A(t) = A_{v,w} = \begin{pmatrix} \Psi \\ \Pi \\ Q \\ P \end{pmatrix} := \begin{pmatrix} w \cdot \nabla & \Delta & w \cdot \nabla & 0 \\ 0 & \nabla \rho & 0 & 0 \\ \langle \cdot, \nabla \rho \rangle & 0 & \langle \nabla \psi_v, \cdot \nabla \rho \rangle & 0 \\ 0 & 0 & 0 & B_v \end{pmatrix}, \tag{4.9}
\]

where \( B_v = \nu_v(I_3 - v \otimes v) \). Furthermore, \( T(t) \) and \( N(t) \) in (4.8) stand for

\[
T(t) = T_{v,w} = \begin{pmatrix} (w - v) \cdot \nabla \psi_v - \dot{v} \cdot \nabla_v \psi_v \\ (w - v) \cdot \nabla \pi_v - \dot{v} \cdot \nabla_v \pi_v \\ v - w \\ -\dot{v} \cdot \nabla_v p_v \end{pmatrix}, \quad N(t) = N(\sigma, Z) = \begin{pmatrix} 0 \\ 0 \\ N_2(Z) \\ N_3(v, Z) \end{pmatrix}, \tag{4.10}
\]

where \( v = v(t), \; w = w(t), \; \sigma = \sigma(t) = (b(t), v(t)), \) and \( Z = Z(t) \). Since \( |Q| \leq \|Z\|_{-\alpha} \) for any \( \alpha \), the estimates (4.1) with \( \overline{Q} = r_{-\alpha}(\tilde{v}) \), (4.5) and (4.7) imply the following

**Lemma 4.1** For any \( \alpha > 0 \)

\[
\|N(\sigma, Z)\|_{\alpha} \leq C(\tilde{v}) \|Z\|^2_{-\alpha} \tag{4.11}
\]

uniformly in \( \sigma, Z \) with \( \|Z\|_{-\alpha} \leq r_{-\alpha}(\tilde{v}) \) and \( |v| < \tilde{v} \).

**Remarks 4.2**

i) The term \( A(t)Z(t) \) in the right hand side of the equation (4.8) is linear in \( Z(t) \), and \( N(t) \) is a high order term in \( Z(t) \). On the other hand, \( T(t) \) is a zero order term which does not vanish at \( Z(t) = 0 \) since \( S(\sigma(t)) \) generally is not a soliton solution if (2.14) does not hold (though \( S(\sigma(t)) \) belongs to the solitary manifold).

ii) Formulas (3.3) and (4.10) imply:

\[
T(t) = -\sum_{l=1}^{3} [(w - v)_l \tau_l + \dot{v}_l \tau_{l+3}] \tag{4.12}
\]

and hence \( T(t) \in \mathcal{T}_{S(\sigma(t))} \mathcal{S}, \; t \in \mathbb{R} \). This fact suggests an unstable character of the nonlinear dynamics along the solitary manifold.

## 5 The Linearized Equation

Here we collect some Hamiltonian and spectral properties of the operator (4.9). The statements of the section are particular cases of those in [19], Section 5 for \( m = 0 \). First, we consider the linear equation

\[
\dot{X}(t) = A_{v,w}X(t), \quad t \in \mathbb{R} \tag{5.1}
\]

with an arbitrary fixed \( v \) such that \( |v| < 1 \), and \( w \in \mathbb{R}^3 \). Let us define the space

\[
\mathcal{E}^+ = H^2(\mathbb{R}^3) \oplus H^1(\mathbb{R}^3) \oplus \mathbb{R}^3 \oplus \mathbb{R}^3.
\]
Lemma 5.1  i) For any \( v, |v| < 1 \) and \( w \in \mathbb{R}^3 \) the equation (5.1) formally can be written as the Hamilton system (cf. (3.1)),
\[
\dot{X}(t) = JD\mathcal{H}_{v,w}(X(t)), \quad t \in \mathbb{R},
\]
where \( D\mathcal{H}_{v,w} \) is the Fréchet derivative of the Hamilton functional
\[
\mathcal{H}_{v,w}(X) = \frac{1}{2} \int \left[ |\Pi|^2 + |\nabla \Psi|^2 \right] dy + \int \Pi w \cdot \nabla \Psi dy + \int \rho(y)Q \cdot \nabla \Psi dy + \frac{1}{2} P \cdot B_v P - \frac{1}{2} (Q \cdot \nabla \psi_v(y), Q \cdot \nabla \rho(y)), \quad X = (\Psi, \Pi, Q, P) \in \mathcal{E}.
\]

ii) Energy conservation law holds for the solutions \( X(t) \in C(\mathbb{R}, \mathcal{E}) \),
\[
\mathcal{H}_{v,w}(X(t)) = \text{const}, \quad t \in \mathbb{R}.
\]

iii) The skew-symmetry relation holds,
\[
\Omega(A_{v,w}X_1, X_2) = -\Omega(X_1, A_{v,w}X_2), \quad X_1 \in \mathcal{E}, \quad X_2 \in \mathcal{E}^+.
\]

Lemma 5.2  The operator \( A_{v,w} \) acts on the tangent vectors \( \tau_j(v) \) to the solitary manifold as follows,
\[
A_{v,w}[\tau_j(v)] = (w - v) \cdot \nabla \tau_j(v), \quad A_{v,w}[\tau_{j+3}(v)] = (w - v) \cdot \nabla \tau_{j+3}(v) + \tau_j(v), \quad j = 1, 2, 3.
\]

We will apply Lemmas 5.1 and 5.2 mainly to the operator \( A_{v,v} \) corresponding to \( w = v \). In that case (5.6) reads
\[
A_{v,v}[\tau_j(v)] = 0, \quad A_{v,v}[\tau_{j+3}(v)] = \tau_j(v), \quad j = 1, 2, 3.
\]
Moreover, the linearized equation acquires the additional essential feature.

Lemma 5.3  Let us assume that \( w = v \) and \( |v| < 1 \). Then the Hamilton functional (5.2) reads, see [19] (5.14)
\[
\mathcal{H}_{v,v}(X) = \frac{1}{2} \int \left( |\Pi + v \cdot \nabla \Psi|^2 + |\Lambda_v^{1/2} \Psi - \Lambda_v^{-1/2} Q \cdot \nabla \rho|^2 \right) dx + \frac{1}{2} P \cdot B_v P \geq 0.
\]
Here \( \Lambda_v \) is the operator defined by (2.9).

Remark 5.4  Lemma 5.3 together with energy conservation (5.4) imply the analyticity of the resolvent \( (A_{v,v} - \lambda)^{-1} \) for \( \Re \lambda > 0 \), see below.

Remark 5.5  For a soliton solution of the system (1.2) we have \( \dot{b} = \dot{v} = 0 \), and hence \( T(t) \equiv 0 \). Thus, the equation (5.1) is the linearization of the system (1.2) on a soliton solution, but on a trajectory \( S(\sigma(t)) \) with \( \sigma(t) \) being nonlinear in \( t \). We will show later that \( T(t) \) is quadratic in \( Z(t) \) if we choose \( S(\sigma(t)) \) to be the symplectic orthogonal projection of \( Y(t) \). Then (5.1) is again the linearization of (1.2).

6  Symplectic Decomposition of the Dynamics

Here we decompose the dynamics in two components: along the manifold \( \mathcal{S} \) and in transversal directions. The equation (1.8) is obtained without any assumption on \( \sigma(t) \) in (1.1). We are going to choose \( S(\sigma(t)) := \Pi Y(t) \), but then we need to know that
\[
Y(t) \in \mathcal{O}_\alpha(\mathcal{S}), \quad t \in \mathbb{R},
\]
with some \( \mathcal{O}_\alpha(\mathcal{S}) \) defined in Lemma 3.1. It is true for \( t = 0 \) and \( \alpha \leq \beta := 4 + \delta \) by (3.7), if \( d_\beta > 0 \) in (2.15) is sufficiently small. Then \( S(\sigma(0)) = \Pi Y(0) \) and \( Z(0) = Y(0) - S(\sigma(0)) \) are well defined.

We select \( \alpha = -\beta \) and will prove below that (6.1) holds if \( d_\beta \) is sufficiently small. First, the a priori estimate (2.7) together with Lemma 3.1 iii) imply that \( \Pi Y(t) = S(\sigma(t)) \) with \( \sigma(t) = (b(t), v(t)) \), and
\[
|v(t)| \leq \tilde{v} < 1, \quad t \in \mathbb{R}
\]
if \( Y(t) \in \mathcal{O}_\alpha(\mathcal{S}) \). Denote by \( r_\alpha(\tilde{v}) \) the positive number from Lemma 3.2 iv) which corresponds to the chosen \( \alpha = -\beta \). Then \( S(\sigma) + Z \in \mathcal{O}_\alpha(\mathcal{S}) \) if \( \sigma = (b, v) \) with \( |v| < \tilde{v} \) and \( \|Z\|_\alpha < r_\alpha(\tilde{v}) \). Note that (3.7) implies \( \|Z(0)\|_\alpha < r_\alpha(\tilde{v}) \) if \( d_\beta \) is sufficiently small. Therefore, \( S(\sigma(t)) = \Pi Y(t) \) and \( Z(t) = Y(t) - S(\sigma(t)) \) are well defined for \( t \geq 0 \) so small that \( \|Z(t)\|_\alpha < r_\alpha(\tilde{v}) \). This is formalized by the following standard definition.
Definition 6.1 \( t_* \) is the “exit time”,

\[
t_* = \sup \{ t > 0 : \| Z(s) \|_{\beta} < r_{-\beta}(\tilde{v}), \ 0 \leq s \leq t \}, \ Z(s) = Y(s) - S(\sigma(s)). \tag{6.3}
\]

One of our main goals is to prove that \( t_* = \infty \) if \( d_\beta \) is sufficiently small. This would follow if we show that

\[
\| Z(t) \|_{-\beta} < r_{-\beta}(\tilde{v})/2, \ 0 \leq t < t_*. \tag{6.4}
\]

Now \( N(t) \) in (6.8) satisfies, by (4.11) with \( \alpha = \beta \), the following estimate:

\[
\| N(t) \|_{\beta} \leq C(\tilde{v})\| Z(t) \|^2_{-\beta}, \ 0 \leq t < t_*\tag{6.5}
\]

6.1 Longitudinal Dynamics: Modulation Equations

From now on we fix the decomposition \( Y(t) = S(\sigma(t)) + Z(t) \) for \( 0 < t < t_* \) by setting \( S(\sigma(t)) = \Pi Y(t) \) which is equivalent to the symplectic orthogonality condition of type (3.5),

\[
Z(t) \perp T_{S(\sigma(t))}S, \ 0 \leq t < t_*.
\tag{6.6}
\]

This allows us to simplify drastically the asymptotic analysis of the dynamical equations (4.8) for the transversal \( \sigma \) parameters is equivalent to the symplectic orthogonality condition of type (3.5), let us write (6.6) in the form

where the vectors \( \tau_j \) span the tangent space \( T_{S(\sigma(t))}S \). Note that \( \sigma(t) = (b(t), v(t)) \), where

\[
|v(t)| \leq \tilde{v} < 1, \ 0 \leq t < t_*\tag{6.8}
\]

by Lemma \[3.4 \text{ iii) } \). It would be convenient for us to use some other parameters \( (c, v) \) instead of \( \sigma = (b, v) \), where \( c(t) = b(t) - \int_0^t v(\tau)d\tau \) and

\[
\dot{c}(t) = \dot{b}(t) - v(t) = w(t) - v(t), \ 0 \leq t < t_*\tag{6.9}
\]

\[
0 = \Omega(v) \left( \begin{array}{c} \dot{c}(t) \\ \dot{v}(t) \end{array} \right) + M_0(\sigma, Z) \left( \begin{array}{c} \dot{c}(t) \\ \dot{v}(t) \end{array} \right) + N_0(\sigma, Z), \ N_{0j}(\sigma, Z) = \Omega(N, \tau_j). \tag{6.10}
\]

where

\[
N(\sigma, Z) = \mathcal{O}(\| Z \|^2_{-\beta})
\tag{6.11}
\]

uniformly in \( \sigma \in \{(b, v) : |v| \leq \tilde{v}\} \).

Proof We differentiate (6.7) in \( t \) and take the equation (4.8) into account. Then (see details of computation in [19], Lemma 6.2) we obtain, in the vector form \[19 \ (6.18)\]:

\[
0 = \Omega(v) \left( \begin{array}{c} \dot{c} \\ \dot{v} \end{array} \right) + M_0(\sigma, Z) \left( \begin{array}{c} \dot{c} \\ \dot{v} \end{array} \right) + N_0(\sigma, Z), \ N_{0j}(\sigma, Z) = \Omega(N, \tau_j). \tag{6.12}
\]

Here the matrix \( \Omega(v) \) has the matrix elements \( \Omega(\tau_j, \tau_j) \) and hence is invertible by Lemma \[3.2 \). The \( 6 \times 6 \) matrix \( M_0(\sigma, Z) \) has the matrix elements \( \sim \| Z \|_{-\beta} \) and hence we can resolve the equation (6.12) with respect to \( (\dot{c}, \dot{v}) \). Then (6.11) follows from Lemma [4.1] with \( \alpha = \beta \), since \( N_0 = \mathcal{O}(\| Z \|^2_{-\beta})\). \( \square \)
6.2 Decay for the Transversal Dynamics

In Section 15 we will show that our main Theorem 2.5 can be derived from the following time decay of the transversal component $Z(t)$:

**Proposition 6.3** Let all conditions of Theorem 2.5 hold. Then $t_\ast = \infty$, and

$$
\|Z(t)\|_{-\beta} \leq \frac{C(\rho, \bar{\nu}, d_\beta)}{(1 + t)^{1+\beta}}, \quad t \geq 0. \tag{6.13}
$$

We will derive (6.13) in Sections 8 – 14 from our equation (4.8) for the transversal component $Z(t)$. This equation can be specified using Lemma 6.2. Namely, by (4.12) and (6.9)

$$
T(t) = -\sum_{l=1}^{3} [\dot{c}_l \tau_l + \dot{v}_l \tau_{l+3}].
$$

Note that the norm $\|T(t)\|_\beta$ is well-defined by (3.4). Then Lemma 6.2 implies

$$
\|T(t)\|_\beta \leq C(\bar{v}) \|Z(t)\|_{-\beta}^2, \quad 0 \leq t < t_\ast. \tag{6.14}
$$

Thus, in (4.8) we should combine the terms $T(t)$ and $\bar{N}(t)$ and obtain

$$
\dot{Z}(t) = A(t)Z(t) + \bar{N}(t), \quad 0 \leq t < t_\ast, \tag{6.15}
$$

where $A(t) = A_{v(t),w(t)}$, and $\bar{N}(t) := T(t) + N(t)$. From (6.14) and (6.5) we obtain that

$$
\|\bar{N}(t)\|_\beta \leq C(\bar{v}) \|Z(t)\|_{-\beta}^2, \quad 0 \leq t < t_\ast. \tag{6.16}
$$

In the remaining part of our paper we will analyze mainly the basic equation (6.15) to establish the decay (6.13). We are going to derive the decay using the bound (6.16) and the orthogonality condition (6.6).

Let us comment on two main difficulties in proving (6.13). The difficulties are common for the problems studied in [5] [8]. First, the linear part of the equation is non-autonomous, hence we cannot apply directly known methods of scattering theory. Similarly to the approach of [5] [8], we reduce the problem to the analysis of the frozen linear equation,

$$
\dot{X}(t) = A_1 X(t), \quad t \in \mathbb{R}, \tag{6.17}
$$

where $A_1$ is the operator $A_{v_1,v_1}$ defined in (4.9) with $v_1 = v(t_1)$ and a fixed $t_1 \in [0,t_\ast)$. Then we estimate the error by the method of majorants. Let us note that recently some methods of freezing were developed by Cuccagna and Mizumachi, [10] [11].

Second, even for the frozen equation (6.17), the decay of type (6.13) for all solutions does not hold without the orthogonality condition of type (6.6). Namely, by (5.7) the equation (6.17) admits the secular solutions

$$
X(t) = \sum_{j=1}^{3} C_j \tau_j(v_1) + \sum_{j=1}^{3} D_j [\tau_j(v_1) t + \tau_{j+3}(v_1)] \tag{6.18}
$$

which arise also by differentiation of the soliton (1.5) in the parameters $a$ and $v_1$ in the moving coordinate $y = x - v_1 t$. Hence, we have to take into account the orthogonality condition (6.6) in order to avoid the secular solutions. For this purpose we will apply the corresponding symplectic orthogonal projection which kills the “runaway solutions” (6.18).

**Remark 6.4** The solution (6.18) lies in the tangent space $T_{S(\sigma_1)} \mathcal{S}$ with $\sigma_1 = (b_1,v_1)$ (for an arbitrary $b_1 \in \mathbb{R}$) that suggests an unstable character of the nonlinear dynamics along the solitary manifold (cf. Remark 4.2 ii)).

**Definition 6.5** i) Denote by $\Pi_v$, $|v| < 1$, the symplectic orthogonal projection of $\mathcal{E}$ onto the tangent space $T_{S(\sigma)} \mathcal{S}$, and $P_v = I - \Pi_v$.

ii) Denote by $Z_v = P_v \mathcal{E}$ the space symplectic orthogonal to $T_{S(\sigma)} \mathcal{S}$ with $\sigma = (b,v)$ (for an arbitrary $b \in \mathbb{R}$).
Note that by the linearity,
\[ \Pi_v Z = \sum \Pi_j(v) \tau_j(v) \Omega(\tau_l(v), Z), \quad Z \in \mathcal{E}, \]
with some smooth coefficients \( \Pi_j(v) \). Hence, the projector \( \Pi_v \), in the variable \( y = x - b \), does not depend on \( b \), and this explains the choice of the subindex in \( \Pi_v \) and \( P_v \). Now we have the symplectic orthogonal decomposition
\[ \mathcal{E} = T_{S(\sigma)} S + Z_v, \quad \sigma = (b, v), \]
and the symplectic orthogonality (6.6) can be written in the following equivalent forms,
\[ \Pi_v(t) Z(t) = 0, \quad P_v(t) Z(t) = Z(t), \quad 0 \leq t < t_+. \]  

Remark 6.6 The tangent space \( T_{S(\sigma)} S \) is invariant under the operator \( A_{v, v} \) by Lemma 5.2. Hence the space \( Z_v \) is also invariant by (5.5): \( A_{v, v} Z \in Z_v \) for sufficiently smooth \( Z \in Z_v \).

The following proposition is one of main ingredients for proving (6.13). Let us consider the Cauchy problem for the equation (6.17) with \( A = A_{v, v} \) for a fixed \( v \), \( |v| < 1 \). Recall that the \( \beta = 4 + \delta, 0 < \delta < 1/2 \).

Proposition 6.7 Let (1.9), the Wiener condition (1.10), and the condition (1.11) hold, \( |v| \leq \bar{v} < 1 \), and \( X_0 \in \mathcal{E} \). Then
i) The equation (6.17), with \( A_1 = A_{v_1, v_1} \), admits the unique solution \( e^{A_{1t}} X_0 := X(t) \in C_b(\mathbb{R}, \mathcal{E}) \) with the initial condition \( X(0) = X_0 \).
ii) If \( X_0 \in Z_{v_1} \cap \mathcal{E}_\beta \), the following decay holds,
\[ ||e^{A_{1t}} X_0||_{-2-\delta} \leq \frac{C(\bar{v})}{(1 + |t|)^{1+\delta}} ||X_0||_\beta, \quad t \in \mathbb{R}. \]  

Part i) follows by standard arguments using the positivity (5.8) of the Hamilton functional. Part ii) will be proved in Sections 7.10 developing general strategy [19] [20]. Namely, the equation (6.17) is a system of four equations involving field components, \( \Psi \) and \( \Pi \) as well as vector components, \( Q \) and \( P \). We apply Fourier-Laplace transform, and express the field components in terms of the vector components. Then we obtain a closed system for the vector components alone and prove their decay. Finally, for the field components we come to a wave equation with a right hand side which has the established decay. This implies the corresponding decay for the field components.

7 Solving the Linearized Equation

Here we start the proof of Proposition 6.7 solving the linearized equations (6.17). Let us apply the Laplace transform
\[ \Lambda X = \tilde{X}(\lambda) = \int_0^\infty e^{-\lambda t} X(t) dt, \quad \text{Re} \lambda > 0 \]

(7.1) to (6.17). The integral converges in \( \mathcal{E} \), since \( ||X(t)||_\mathcal{E} \) is bounded by Proposition 6.7 i). The analyticity of \( \tilde{X}(\lambda) \) and Paley-Wiener arguments should provide the existence of a \( \mathcal{E} \)-valued distribution \( X(t) = (\Psi(t), \Pi(t), Q(t), P(t)) \), \( t \in \mathbb{R} \), with a support in \([0, \infty)\). Formally,
\[ \Lambda^{-1} \tilde{X} = X(t) = \frac{1}{2\pi} \int_\mathbb{R} e^{i\omega t} \tilde{X}(i\omega + 0) d\omega, \quad t \in \mathbb{R}. \]

(7.2)

To prove the decay (6.22), we have to study the smoothness of \( \tilde{X}(i\omega + 0) \) at \( \omega \in \mathbb{R} \). After the Laplace transform the equation (6.17) becomes
\[ \lambda \tilde{X}(\lambda) = A_1 \tilde{X}(\lambda) + X_0, \quad \text{Re} \lambda > 0. \]

In detail (for simplicity we write \( v \) instead of \( v_1 \) in this section),
\[ \Pi(y) + v \cdot \nabla \tilde{\Psi}(y) - \lambda \tilde{\Psi}(y) = -\tilde{\Psi}_0(y) \]
\[ \Delta \tilde{\Psi}(y) + v \cdot \nabla \tilde{\Pi}(y) + \tilde{Q} \cdot \nabla \rho(y) - \lambda \tilde{\Pi}(y) = -\tilde{\Pi}_0(y) \]
\[ B_v \tilde{P} - \lambda \tilde{Q} = -Q_0 \]
\[ -\langle \nabla \tilde{\Psi}(y), \rho(y) \rangle + \langle \nabla \psi_v(y), \tilde{Q} \cdot \nabla \rho(y) \rangle - \lambda \tilde{P} = -P_0 \]

\( y \in \mathbb{R}^3 \).
Let us consider the first two equations. In Fourier space they become
\[
\hat{\Pi}(k) - i\nu k \hat{\Psi}(k) - \lambda \hat{\Psi}(k) = -\hat{\Psi}_0(k) \\
-k^2 \hat{\Psi}(k) - (i\nu k + \lambda) \hat{\Pi}(k) = -\hat{\Pi}_0(k) + i\tilde{Q} k \tilde{\rho}(k)
\]
This implies
\[
\hat{\Psi} = \frac{1}{D} ((i\nu k + \lambda) \hat{\Psi}_0 + \hat{\Pi}_0 - i\tilde{Q} k \tilde{\rho}),
\]
\[
\hat{\Pi} = \frac{1}{D} (-k^2 \hat{\Psi}_0 + (i\nu k + \lambda) \hat{\Pi}_0 - i(i\nu k + \lambda) k \tilde{Q} \tilde{\rho}),
\]
where
\[
\hat{D} = \hat{D}(\lambda) = k^2 + (i\nu k + \lambda)^2.
\]
From now on we use the system of coordinates in \(x\)-space in which \(v = (|v|, 0, 0)\), hence \(\nu k = |v| k_1\). Substitute (7.5) to the 4-th equation of (7.3) and obtain
\[
\int \frac{ik}{D} ((i\nu k + \lambda) \hat{\Psi}_0 + \hat{\Pi}_0 - i\tilde{Q} k \tilde{\rho}) dk + \int k \hat{\psi}_v k \tilde{Q} \tilde{\rho} dk - \lambda \hat{P} = -P_0.
\]
Since \(\hat{\psi}_v = -\hat{\rho} / (k^2 - (kv)^2)\), we come to
\[
(K - H(\lambda)) \hat{Q} + \lambda \hat{P} = P_0 + \Phi(\lambda).
\]
Here
\[
\Phi(\lambda) = \Phi(\Psi_0, \Pi_0)(\lambda) := i \int \frac{k}{D} ((i\nu k + \lambda) \hat{\Psi}_0 + \hat{\Pi}_0) \tilde{\rho} dk = i (\frac{i\nu k + \lambda}{D} \hat{\Psi}_0 + \hat{\Pi}_0, k \tilde{\rho}),
\]
and \(K, H(\lambda)\) are 3 \times 3-matrices with the matrix elements
\[
K_{ij} = \int \frac{k_i k_j |\tilde{\rho}(k)|^2 dk}{k^2 - (|v| k_1)^2}, \quad H_{ij}(\lambda) = \int \frac{k_i k_j |\tilde{\rho}(k)|^2 dk}{k^2 + (i|v| k_1 + \lambda)^2}.
\]
The matrix \(K\) is diagonal and positive definite since \(\tilde{\rho}(k)\) is spherically symmetric and not identically zero by (1.10). The matrix \(H(\lambda)\) is well defined for \(\text{Re} \lambda > 0\) since the denominator does not vanish. The matrix \(H\) is diagonal similar to \(K\). Indeed, if \(i \neq j\), then at least one of these indexes is not equal to one, and the integrand in (7.9) is odd with respect to the corresponding variable by (1.9). Finally the 3-rd and the 4-th equations of (7.3) become
\[
M(\lambda) \begin{pmatrix} \hat{Q} \\ \hat{P} \end{pmatrix} = \begin{pmatrix} Q_0 \\ P_0 + \Phi(\lambda) \end{pmatrix}, \quad \text{where} \quad M(\lambda) = \begin{pmatrix} \lambda I_3 & B_v \\ -F(\lambda) & \lambda I_3 \end{pmatrix}, \quad F(\lambda) := H(\lambda) - K.
\]

**Remark 7.1** Note that
\[
\Phi(\lambda) = \Phi(\Psi_0, \Pi_0)(\lambda) = \Lambda \langle W^1(t)(\Psi_0, \Pi_0), \nabla \rho \rangle,
\]
where \(W^1(t)\) is the first component of the dynamical group \(W(t)\) defined below by (10.5) and \(\Lambda\) is the Laplace transform (1.1).

Let us proceed to \(x\)-representation. We invert the matrix of the system (7.4) and obtain
\[
\begin{pmatrix} -(i\nu k + \lambda) & 1 \\ -k^2 & -(i\nu k + \lambda) \end{pmatrix}^{-1} = \left( \begin{pmatrix} (i\nu k + \lambda)^2 + k^2 \end{pmatrix}^{-1} \right) \begin{pmatrix} -1 \\ -(i\nu k + \lambda) \end{pmatrix}.
\]
Taking the inverse Fourier transform, we obtain the corresponding fundamental solution
\[
G_\lambda(y) = \begin{pmatrix} v \cdot \nabla - \lambda & -1 \\ -\Delta & v \cdot \nabla - \lambda \end{pmatrix} g_\lambda(y),
\]
where \(g_\lambda(y)\) is the unique tempered fundamental solution of the determinant
\[
D = D(\lambda) = -\Delta + (-v \cdot \nabla + \lambda)^2.
\]
Thus,
\[
g_\lambda(y) = F_k^{-1} \begin{pmatrix} 1 \\ \frac{1}{k^2 + (i\nu k + \lambda)^2} \end{pmatrix} = F_k^{-1} \begin{pmatrix} 1 \\ \frac{1}{k^2 + (i|v| k_1 + \lambda)^2} \end{pmatrix}, \quad y \in \mathbb{R}^3.
\]
Note that the denominator does not vanish for \(\text{Re} \lambda > 0\). This implies
Lemma 7.2 The operator $G_\lambda$ with the integral kernel $G_\lambda(y - y')$ is continuous operator $H^1(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3) \to H^2(\mathbb{R}^3) \oplus H^1(\mathbb{R}^3)$ for $\Re \lambda > 0$.

From (7.5) and (7.6) we obtain the convolution representation

$$
\Psi = -(v \cdot \nabla - \lambda)g_\lambda \ast \Psi_0 + g_\lambda \ast \Pi_0 + (g_\lambda \ast \nabla \rho) \cdot Q
$$

(7.15)

$$
\Pi = \Delta g_\lambda \ast \Psi_0 - (v \cdot \nabla - \lambda)g_\lambda \ast \Pi_0 - (v \cdot \nabla - \lambda)(g_\lambda \ast \nabla \rho) \cdot Q
$$

Let us compute $g_\lambda(y)$ explicitly. First consider the case $v = 0$. The fundamental solution of the operator $-\Delta + \lambda^2$ is

$$
g_\lambda(y) = \frac{e^{-\lambda|y|}}{4\pi|y|}.
$$

(7.16)

Thus, in the case $v = 0$ we have

$$
G_\lambda(y - y') = \left( \begin{array}{cc}
-\lambda & -1 \\
-\Delta & -\lambda
\end{array} \right) \frac{e^{-\lambda|y - y'|}}{4\pi|y - y'|}.
$$

For general $v = (|v|, 0, 0)$ with $|v| < 1$ the denominator in (7.14), which is the Fourier symbol of $D$, reads

$$
\hat{D}(k) = k^2 + (i|v|k_1 + \lambda)^2 = (1 - v^2)k_1^2 + k_2^2 + k_3^2 + 2i|v|k_1\lambda + \lambda^2
$$

(7.17)

\[
= (1 - v^2)(k_1 + i|v|\lambda)^2 + k_2^2 + k_3^2 + \kappa^2,
\]

where

$$
\kappa^2 = \frac{v^2\lambda^2}{1 - v^2} + \lambda^2 = \frac{\lambda^2}{1 - v^2}.
$$

(7.18)

Therefore, setting $\gamma := 1/\sqrt{1 - v^2}$, we have

$$
\kappa = \gamma\lambda.
$$

(7.19)

Return to $x$-space:

$$
D = -\frac{1}{\gamma^2}(\nabla_1 + \gamma\kappa_1)^2 - \nabla_2^2 - \nabla_3^2 + \kappa^2,
$$

$\kappa_1 := \gamma|v|\lambda$

(7.20)

Define $\tilde{y}_1 := \gamma y_1$ and $\tilde{\nabla}_1 := \partial/\partial\tilde{y}_1$. Then

$$
D = -(\tilde{\nabla}_1 + \kappa_1)^2 - \nabla_2^2 - \nabla_3^2 + \kappa^2.
$$

(7.21)

Thus, its fundamental solution is

$$
g_\lambda(y) = \frac{e^{-\kappa|\tilde{y} - \kappa_1\tilde{y}_1}}{4\pi|\tilde{y}|}, \quad \tilde{y} := (\gamma y_1, y_2, y_3).
$$

(7.22)

By (7.19), (7.20) we obtain

$$
0 < \Re \kappa_1 < \Re \kappa, \quad \Re \lambda > 0.
$$

(7.23)

Let us state the result which we have got above.

Lemma 7.3 i) The operator $D = D(\lambda)$ is invertible in $L^2(\mathbb{R}^3)$ for $\Re \lambda > 0$ and its fundamental solution $g_\lambda(\cdot)$ decays exponentially in $y$.

ii) The formulas (7.22) and (7.19), (7.20) imply that the distribution $g_\lambda(\cdot)$ admits an analytic continuation in the parameter $\lambda$ from the domain $\Re \lambda > 0$ to the entire complex plane $\mathbb{C}$.

Lemma 7.4 The matrix function $M(\lambda)$ (respectively, $M^{-1}(\lambda)$) admits an analytic (respectively meromorphic) continuation from the domain $\Re \lambda > 0$ to the entire complex plane $\mathbb{C}$.
Proof From the first equation of \((7.15)\) and the last equation of \((7.3)\) it follows that
\[
H_{jj}(\lambda) = \langle g_\lambda \ast \partial_j \rho, \partial_j \rho \rangle
\]
and thus, by \((7.22)\),
\[
|H_{jj}(\lambda)| = |\langle g_\lambda \ast \partial_j \rho, \partial_j \rho \rangle| \leq \int \frac{C}{|x-y|} \partial_j \rho(x) \partial_j \rho(y) dx dy < \infty.
\]
By \((7.9)\), \((7.10)\) this implies
\[
\sup_{\Re \lambda \geq 0} |F(\lambda)| < \infty. \tag{7.25}
\]
The analytic continuation of \(M(\lambda)\) exists by the expressions \((7.24)\) and Lemma \((7.3)\) ii), since the function \(\rho(x)\) is compactly supported by \((1.9)\). The inverse matrix is then meromorphic since it exists for large \(\Re \lambda\). The latter follows from \((7.10)\) since \(H(\lambda) \to 0\), \(\Re \lambda \to \infty\), by \((7.9)\).

8 Regularity in Continuous Spectrum

Proposition 8.1 The matrix \(M^{-1}(i\omega)\) is analytic in \(\omega \in \mathbb{R} \setminus \{0\}\).

Proof It suffices to prove that the limit matrix \(M(i\omega) := M(i\omega + 0)\) is invertible for \(\omega \neq 0\), \(\omega \in \mathbb{R}\) if \(\rho\) satisfies the Wiener condition \((1.10)\), and \(|v| < 1\). Let \(|\omega| > 0\). One has
\[
\det M(i\omega) = \det \begin{pmatrix} i\omega I_3 & -B_v \\ -F(i\omega) & i\omega I_3 \end{pmatrix} = -(\omega^2 + v^3 f_1)(\omega^2 + v f)^2, \quad \omega \in \mathbb{R}, \tag{8.1}
\]
where \(F(i\omega) := F(i\omega + 0)\), \(f_1 := F_{11}(i\omega)\), and \(f := F_{22}(i\omega) = F_{33}(i\omega)\). The invertibility of \(M(i\omega)\) follows from \((8.1)\) by the following lemma, whose proof is based on the Sokhotsky-Plemelj formula, see [39, Chapter VII, formula (58)].

Lemma 8.2 If \((1.11)\) holds, then for \(\omega \in \mathbb{R}\) the imaginary part of the matrix \(\frac{\omega}{|\omega|} F(i\omega)\) is negative definite, i.e. \(\frac{\omega}{|\omega|} \text{Im} F_{jj}(i\omega) < 0\), \(j = 1, 2, 3\).

Proof Since \(F(i\omega) = H(i\omega + 0) - K\), where the matrix \(K\) is real, we will consider only the matrix \(H(i\omega + 0)\). For \(\varepsilon > 0\) we have
\[
H_{jj}(i\omega + \varepsilon) = \int \frac{k^2 |\hat{\rho}(k)|^2 dk}{k^2 - (|v| k_1 + \omega - i\varepsilon)^2}, \quad j = 1, 2, 3. \tag{8.2}
\]
Consider the denominator
\[
\hat{D}(i\omega + \varepsilon, k) = k^2 - (|v| k_1 + \omega - i\varepsilon)^2.
\]
\(\hat{D}(i\omega, k) = 0\) on the ellipsoid \(T_\omega\) if \(|\omega| > 0\), where
\[
T_\omega = \{ k : (\nu k_1 - \frac{|v|\omega}{\nu})^2 + k_2^2 + k_3^2 = \frac{\omega^2}{\nu^2} \},
\]
here \(\nu = \sqrt{1 - v^2}\). From the Sokhotsky-Plemelj formula for \(C^1\)-functions it follows that
\[
\text{Im} H_{jj}(i\omega + 0) = -\frac{\omega}{|\omega|} \pi \int_{T_\omega} \frac{k^2 |\hat{\rho}(k)|^2}{|\nabla \hat{D}(i\omega, k)|} dS, \tag{8.3}
\]
where \(dS\) is the element of the surface area. This immediately implies the statement of the Lemma since the integrand in \((8.3)\) is positive by the Wiener condition \((1.10)\). This completes the proofs of the lemma and the Proposition 8.1.

Remark 8.3 The proof of Lemma \((8.2)\) is the unique point in the paper where the Wiener condition is indispensable.
9 Time Decay of the Vector Components

Here we prove the decay \((6.22)\) for the vector components \(Q(t)\) and \(P(t)\) of the solution \(e^{A_1 t} X_0\). Formula \((7.10)\) expresses the Laplace transforms \(\tilde{Q}(\lambda), \tilde{P}(\lambda)\). Hence, the components are given by the integral

\[
\begin{pmatrix}
Q(t) \\
P(t)
\end{pmatrix}
= \frac{1}{2\pi} \int e^{i\omega t} M^{-1}(i\omega) \begin{pmatrix} Q_0 \\ P_0 + \Phi(i\omega) \end{pmatrix} d\omega. \tag{9.1}
\]

Let us recall that in Proposition \((8.7) ii)\) we assume that

\[X_0 \in Z_0 \cap E, \quad \beta = 4 + \delta, \quad 0 < \delta < 1/2. \tag{9.2}\]

**Theorem 9.1** The functions \(Q(t), P(t)\) are continuous for \(t \geq 0\), and

\[|Q(t)| + |P(t)| \leq \frac{C(\rho, \tilde{\nu})}{(1 + |t|)^{1+\delta}} \|X_0\|_\beta, \quad t \geq 0. \tag{9.3}\]

**Proof** Note that the Proposition \((8.1)\) alone is not sufficient for the proof of the convergence and decay of the integral \((9.1)\). We need an additional information about the regularity of the matrix \(M^{-1}(i\omega)\) at its singular point \(\omega = 0\), and some bounds at \(|\omega| \to \infty\).

Let us split the integral \((9.1)\) in two terms using the partition of unity \(\zeta_1(\omega) + \zeta_2(\omega) = 1, \omega \in \mathbb{R}\):

\[
\begin{pmatrix}
Q(t) \\
P(t)
\end{pmatrix}
= \frac{1}{2\pi} \int e^{i\omega t} (\zeta_1(\omega) + \zeta_2(\omega)) \begin{pmatrix} \tilde{Q}(i\omega) \\ \tilde{P}(i\omega) \end{pmatrix} d\omega = \begin{pmatrix}
Q_1(t) \\
P_1(t)
\end{pmatrix} + \begin{pmatrix}
Q_2(t) \\
P_2(t)
\end{pmatrix}, \tag{9.4}
\]

where the functions \(\zeta_k(\omega) \in C^\infty(\mathbb{R})\) are supported by

\[\text{supp} \zeta_1 \subset \{\omega \in \mathbb{R} : |\omega| < r + 1\}, \quad \text{supp} \zeta_2 \subset \{\omega \in \mathbb{R} : |\omega| > r\}, \tag{9.5}\]

where \(r\) is introduced below in Lemma \((9.3)\). We prove the decay \((9.3)\) for \((Q_1, P_1)\) and \((Q_2, P_2)\) in Propositions \((9.4)\) and \((9.2)\) respectively.

**Proposition 9.2** The functions \(Q_2(t), P_2(t)\) are continuous for \(t \geq 0\), and

\[|Q_2(t)| + |P_2(t)| \leq \frac{C(\rho, \tilde{\nu})}{(1 + |t|)^{3+\delta}} \|X_0\|_\beta. \tag{9.6}\]

**Proof** First we study the asymptotic behavior of \(M^{-1}(\lambda)\) at infinity. Let us recall that \(M^{-1}(\lambda)\) was originally defined for \(\text{Re} \lambda > 0\), but it admits a meromorphic continuation to \(\mathbb{C}\) (see Lemma \((7.4)\)).

**Lemma 9.3** There exist a matrix \(R_0\) and a matrix-function \(R_1(\omega)\), such that

\[M^{-1}(i\omega) = \frac{R_0}{\omega} + R_1(\omega), \quad |\omega| > r > 0, \quad \omega \in \mathbb{R}, \tag{9.7}\]

where, for every \(k = 0, 1, 2, \ldots\),

\[|\partial^k \omega R_1(\omega)| \leq \frac{C_k}{|\omega|^r}, \quad |\omega| > r > 0, \quad \omega \in \mathbb{R}, \tag{9.8}\]

\(r\) is sufficiently large.

**Proof** The statement follows from the explicit formulas \((A.4)\) to \((A.8)\) for the inverse matrix \(M^{-1}(i\omega)\) and from the bound \((7.25)\).

Further, \((9.3)\) implies that

\[
\begin{pmatrix}
Q_2(t) \\
P_2(t)
\end{pmatrix}
= \frac{1}{2\pi} \int e^{i\omega t} \zeta_2(\omega) M^{-1}(i\omega) \begin{pmatrix} Q_0 \\ P_0 + \Phi(i\omega) \end{pmatrix} d\omega
\]

\(\square\)
\[= s(t) \left( \begin{array}{c} Q_0 \\ P_0 \end{array} \right) + s * \left( \begin{array}{c} 0 \\ f \end{array} \right), \] (9.9)

where (see (7.2))
\[s(t) := \Lambda^{-1} \left[ \zeta_2(\omega)M^{-1}(i\omega) \right] \]

and
\[f(t) := \Lambda^{-1}\Phi(i\omega) = \langle W^1(t)(\Psi_0, \Pi_0), \nabla \rho \rangle, \] (9.10)
since \(\Phi\) is given by (7.8) and (7.11). Note that \(s(t)\) is continuous for \(t \geq 0\), and
\[|s(t)| = O(t^{-N}), \quad t \to \infty, \quad \forall N > 0. \] (9.11)

by (9.7)-(9.8). On the other hand, recall that, under the conditions of Proposition 6.7 and Theorem 2.5, \((\Psi_0, \Pi_0) \in F_\beta\) with \(\beta = 4 + \delta\) where \(\delta > 0\). Then we obtain that
\[|f(t)| \leq C(\rho, \bar{\nu})\|X_0\|_\beta (1 + t)^{1+\delta}, \quad t \geq 0. \] (9.12)

by Lemma 10.2 below with \(\alpha = \beta\). Hence, (9.6) follows from (9.9) by (9.11) and (9.12).

Now let us prove the decay for \(Q_1(t)\) and \(P_1(t)\). In this case the proof will rely substantially on the symplectic orthogonality conditions. Namely, (9.2) implies that
\[Q_1(t) = 1\omega L_{11}(\omega)Q_0 + 1\omega L_{12}(\omega)(P_0 + \Phi(i\omega)), \] (9.17)
\[P_0 + \Phi(0) = 0 \quad \text{and} \quad B_v^{-1}Q_0 + \Phi'(0) = 0. \] (9.19)

Proposition 9.4 The functions \(Q_1(t)\) and \(P_1(t)\) are continuous for \(t \geq 0\), and
\[|Q_1(t)| + |P_1(t)| \leq C(\rho, \bar{\nu})\|X_0\|_\beta (1 + t)^{1+\delta}, \quad t \geq 0. \] (9.14)

Proof First, we obtain the formulas for the Fourier transforms \(\tilde{Q}(i\omega)\) and \(\tilde{P}(i\omega)\).

Lemma 9.5 The matrix \(M^{-1}(i\omega)\) can be represented as follows,
\[L(\omega) := M^{-1}(\omega) = \left( \begin{array}{cc} 1\omega L_{11} & 1\omega L_{12} \\ 1\omega L_{21} & 1\omega L_{22} \end{array} \right), \] (9.15)

where \(L_{ij}(\omega), i, j = 1, 2\) are smooth diagonal 3 \times 3-matrices, \(L_{ij}(\omega) \in C^\infty(-r-1; r+1),\) and
\[L_{11} = iL_{12}B_v^{-1}. \] (9.16)

For proof see Appendix A. Now (7.10) implies that the vector components are given by
\[\tilde{Q}(i\omega) = 1\omega L_{11}(\omega)Q_0 + 1\omega L_{12}(\omega)(P_0 + \Phi(i\omega)), \] (9.17)
\[\tilde{P}(i\omega) = L_{21}(\omega)Q_0 + 1\omega L_{22}(\omega)(P_0 + \Phi(i\omega)), \] (9.18)

Next we calculate the symplectic orthogonality conditions (9.13).

Lemma 9.6 The symplectic orthogonality conditions (9.13) read
\[P_0 + \Phi(0) = 0 \quad \text{and} \quad B_v^{-1}Q_0 + \Phi'(0) = 0. \] (9.19)
For proof see Appendix B.

Now we can prove Proposition 9.4.

**Step i)** Let us prove (9.14) for \( P_1(t) \) relying on the representation (9.18). Namely, (9.4) and (9.18) imply

\[
P_1(t) = \Lambda^{-1}J_1(\omega)Q_0 + \Lambda^{-1}J_1(\omega)L_{22}(\omega)P_0 + \Phi(i\omega) = P_1(t) + P''_1(t).
\]

The first term \( P'_1(t) \) decays like \( Ct^{-\infty}||X_0||_\beta \) by Lemma 9.5. The second term admits the convolution representation \( P''_1(t) = \Lambda^{-1}J_1L_{22} * g(t) \), where

\[
g(t) = \Lambda^{-1}\frac{P_0 + \Phi(i\omega)}{\omega}.
\]

Now we use the symplectic orthogonality conditions (9.19) and obtain

\[
g(t) = \Lambda^{-1}\frac{\Phi(i\omega) - \Phi(0)}{\omega} = i\int_0^t f(s)ds.
\]

Therefore, \( P''_1(t) \) decays like \( Ct^{-(2+\delta)}||X_0||_\beta \) for \( t \geq 0 \), since by (9.12)

\[
|g(t)| \leq C(\rho, \bar{v})(1 + t)^{-\delta}||X_0||_\beta, \quad t \geq 0.
\]

**Step ii)** Now let us prove (9.14) for \( Q_1(t) \). By (9.17), (9.16), and the symplectic orthogonality conditions (9.19),

\[
\dot{Q}(i\omega) = \frac{L_{12}}{\omega} \left( iB^{-1}_vQ_0 + \frac{P_0 + \Phi(i\omega)}{\omega} \right) = \frac{L_{12}}{\omega} \left( iB^{-1}_vQ_0 + \frac{\Phi(i\omega) - \Phi(0)}{\omega} \right) = \frac{L_{12}}{\omega} \left( iB^{-1}_vQ_0 + \frac{\Phi(i\omega) - \Phi(0)}{\omega} \right).
\]

\[
\frac{L_{12}}{\omega}(iB^{-1}_vQ_0 + \dot{Q}(i\omega)) = L_{12} \frac{iB^{-1}_vQ_0 + \Phi(0) + \Phi(i\omega) - \Phi(0)}{\omega} = \frac{L_{12}}{\omega} \left( \Phi(i\omega) - \Phi(0) \right),
\]

since \( iB^{-1}_vQ_0 + \dot{g}(0) = 0 \) by the symplectic orthogonality conditions (9.19), because \( \dot{g}(0) = i\Phi'(0) \). Thus, \( Q_1(t) = \Lambda^{-1}J_1(\omega)L_{12} * h(t) \) by (9.4), where

\[
h(t) := \Lambda^{-1}\frac{\Phi(i\omega) - \Phi(0)}{\omega} = i\int_0^t g(s)ds,
\]

similarly to (9.20). This integral decays like \( Ct^{\delta}||X_0||_\beta \) for \( t \geq 0 \) by (9.21), hence (9.14) for \( Q_1(t) \) is proved. The proof of Proposition 9.4 and Theorem 9.1 is complete.

## 10 Time Decay of Fields

Here we construct the field components \( \Psi_\alpha(x,t), \Pi_\alpha(x,t) \) of the solution \( X(t) \) and prove their decay corresponding to (6.22). Let us denote \( F(t) = (\Psi(\cdot,t), \Pi(\cdot,t)) \). We will construct the fields solving the first two equations of (6.17), where \( A \) is given by (11.9). These two equations have the form

\[
\dot{F}(t) = \left( \begin{array}{c}
v \cdot \nabla \\
\Delta \end{array} \right) F + \left( \begin{array}{c}
0 \\
v \cdot \nabla Q(t) \end{array} \right).
\]

By Theorem 9.1 we know that \( Q(t) \) is continuous and

\[
|Q(t)| \leq C(\rho, \bar{v})||X_0||_\beta \left( \frac{1}{1 + t} \right)^{1+\delta}, \quad t \geq 0.
\]

Hence, the Proposition 6.7 is reduced now to the following
Proposition 10.1  i) Let a function $Q(t) \in C([0, \infty); \mathbb{R}^3)$, and $F_0 \in \mathcal{F}$. Then the equation (10.1) admits a unique solution $F(t) \in C[0, \infty; \mathcal{F})$ with the initial condition $F(0) = F_0$.

ii) If $X_0 = (F_0; Q_0, P_0) \in C_{\beta}$ and the decay (10.2) holds, the corresponding fields also decay uniformly in $v$:

$$
\|F(t)\|_{-2-\delta} \leq \frac{C(\rho, \tilde{v})\|X_0\|_{\beta}}{(1 + t)^{1+\delta}}, \quad t \geq 0,
$$

(10.3)

for $|v| \leq \tilde{v}$ with any $\tilde{v} \in (0; 1)$.

Proof  The statement i) follows from the Duhamel representation

$$
F(t) = W(t)F_0 + \left[ \int_0^t W(t-s) \left( \frac{0}{\nabla \rho} \cdot Q(s) \right) ds \right], \quad t \geq 0,
$$

(10.4)

where $W(t)$ is the dynamical group of the modified wave equation

$$
\hat{F}(t) = \left( \begin{array}{cc} v \cdot \nabla & 1 \\ \Delta & v \cdot \nabla \end{array} \right) F(t).
$$

(10.5)

The group $W(t)$ can be expressed through the group $W_0(t)$ of the wave equation

$$
\hat{\Phi}(t) = \left( \begin{array}{cc} 0 & 1 \\ \Delta & 0 \end{array} \right) \Phi(t).
$$

(10.6)

Namely, the problem (10.6) corresponds to (10.5), when $v = 0$, and it is easy to see that

$$
[W(t)F(0)](x) = [W_0(t)F(0)](x + vt), \quad x \in \mathbb{R}^3, \quad t \in \mathbb{R}.
$$

(10.7)

The identity (10.7) implies the energy conservation law for the group $W(t)$: for $(\Psi(\cdot, t), \Pi(\cdot, t)) = W(t)F(0)$ we have

$$
\int (|\Pi(x, t) - v \cdot \nabla \Psi(x, t)|^2 + |\nabla \Psi(x, t)|^2) \, dx = \text{const}, \quad t \in \mathbb{R}.
$$

In particular, this gives by (2.2)

$$
\|W(t)F_0\|_{\mathcal{F}} \leq C(\tilde{v})\|F_0\|_{\mathcal{F}}, \quad t \in \mathbb{R}.
$$

(10.8)

This estimate and (10.3) imply the statement i).

Let us proceed to the statement ii).

Lemma 10.2  For $\tilde{v} < 1$ and $F_0 \in \mathcal{F}_\alpha$, $\alpha > 1$, the following decay holds,

$$
\|W(t)F_0\|_{-\alpha} \leq \frac{C(\alpha, \tilde{v})\|F_0\|_{\alpha}}{(1 + t)^{\alpha-1}}, \quad t \geq 0,
$$

(10.9)

for the dynamical group $W(t)$ corresponding to the modified wave equation (10.5) with $|v| < \tilde{v}$.

Proof  For the case $v = 0$ the proof is provided in [26]. For a nonzero $v$ with $|v| < \tilde{v}$ the proof is similar, we provide it for convenience.

We should estimate $\|W(t)F_0\|_{-\alpha}$ for large $t > 0$. Set $\varepsilon = (1 - \tilde{v})/2$. For an arbitrary sufficiently large $t \geq 1$ let us split the initial function $F_0$ in two terms, $F_0 = F'_{0,t} + F''_{0,t}$ such that

$$
\|F'_{0,t}\|_{\alpha} + \|F''_{0,t}\|_{\alpha} \leq C\|F_0\|_{\alpha}, \quad t \gg 1,
$$

(10.10)

where $C$ does not depend on $t$, and

$$
F'_{0,t}(x) = 0, \quad |x| > \varepsilon t, \quad F''_{0,t}(x) = 0, \quad |x| < \varepsilon t - 1.
$$

(10.11)

For an arbitrary $f \in \tilde{H}^1$ and $\alpha > 1$ one has $|f|_{-\alpha} \leq C\|f\|_{\tilde{H}^1}$, see [26], formula (2.9). Now the estimate for $W(t)F''_{0,t}$ follows by (10.8), (10.11) and (10.10):

$$
\|W(t)F''_{0,t}\|_{-\alpha} \leq C\|W(t)F''_{0,t}\|_{\mathcal{F}} \leq C\|F''_{0,t}\|_{\mathcal{F}} \leq C_1(\tilde{v})\|F''_{0,t}\|_{\alpha}(1+|t|)^{-\alpha} \leq C_2(\tilde{v})\|F_0\|_{\alpha}(1+|t|)^{-\alpha}, \quad t \geq 1,
$$

(10.12)
It remains to estimate $W(t)F_{0,t}'$. First note that

$$W_0(t)F'_{0,t}(x) = 0 \text{ for } |x| < (1 - \varepsilon)t$$

(10.13)

by the strong Huygen’s principle for the group $W_0(t)$. The principle reads

$$W_0(x - y, t) = 0, \quad |x - y| \neq t,$$

(10.14)

where $W_0(z,t)$ is the integral (distribution) matrix kernel of the operator $W_0(t)$. Further, from (10.13) it follows that

$$[W(t)F'_{0,t}](x) = 0 \text{ for } |x| < \varepsilon t$$

by (10.7) and since $|v| < \tilde{v} = 1 - 2\varepsilon$.

For an arbitrary $f \in \dot{H}^1$ such that $f(x) = 0$ in the region $\{|x| < \varepsilon t\}$, one has $|f|_{-\alpha} \leq C(\tilde{v})t^{-\alpha + 1}\|f\|_{\dot{H}^1}$, see [26], the proof of Proposition 2.1. Applying to $f = W(t)F_{0,t}'$ we obtain by (10.8) that,

$$\|W(t)F'_{0,t}\|_{-\alpha} \leq C(\tilde{v})t^{-\alpha + 1}\|W(t)F_{0,t}'\|_{\mathcal{F}} \leq Ct^{-\alpha + 1}\|F_0\|_{\mathcal{F}} \leq Ct^{-\alpha + 1}\|F_{0,t}'\|_{\mathcal{F}} \leq Ct^{-\alpha + 1}\|F_0\|_{\mathcal{F}}.$$

The proof is complete. □

Now the statement ii) of Proposition [10.1] follows from the Lemma [10.2] and the Duhamel representation (10.3). Indeed,

$$\|W(t)F_0\|_{-2-\delta} \leq Ct^{-1-\delta}\|F_0\|_{2+\delta} \leq Ct^{-1-\delta}\|X_0\|_{2+\delta} \leq Ct^{-1-\delta}\|X_0\|_{\beta}$$

by Lemma [10.2] with $\alpha = 2 + \delta$. Further,

$$\| \int_0^t W(t-s) \left( \begin{array}{c} 0 \\ \nabla \rho \cdot Q(s) \\ \end{array} \right) ds \|_{-2-\delta} \leq C \int_0^t \| (0, \nabla \rho \cdot Q(s)) \|_{2+\delta} ds \leq C' \int_0^t \frac{|Q(s)| ds}{(1 + (t-s))^{1+\delta}} \leq C'' \|X_0\|_{\beta} \int_0^t \frac{ds}{(1 + (t-s))^{1+\delta}(1 + s)^{1+\delta}}$$

by Lemma [10.2] with $\alpha = 2 + \delta$, regularity properties of $\rho$, and (10.2). The last integral decays like $(1 + t)^{-1-\delta}$ by a well known result on decay of a convolution.

The proof of Proposition [6.7] is complete. □

11 Frozen Form of Transversal Dynamics

In next four sections we will prove the transversal decay (6.13) relying on the Proposition [6.7]. First, let us fix an arbitrary $t_1 \in [0, t_*]$, and rewrite the equation (6.15) in a “frozen form”

$$\dot{Z}(t) = A_1Z(t) + (A(t) - A_1)Z(t) + \tilde{N}(t), \quad 0 \leq t < t_*\quad (11.1)$$

where $A_1 = A_{v(t_1), v(t_1)}$ and

$$A(t) - A_1 = \begin{pmatrix} [w(t) - v(t_1)] \cdot \nabla & 0 & 0 & 0 \\ 0 & [w(t) - v(t_1)] \cdot \nabla & 0 & 0 \\ 0 & 0 & 0 & B_v(t) - B_v(t_1) \\ 0 & 0 & \langle \nabla (\psi_v(t) - \psi_v(t_1)), \cdot \nabla \rho \rangle & 0 \end{pmatrix}.$$

The next trick is important since it allows us to kill the “bad terms” $[w(t) - v(t_1)] \cdot \nabla$ in the operator $A(t) - A_1$.

**Definition 11.1** Let us change the variables $(y, t) \mapsto (y_1, t) = (y + d_1(t), t)$ where

$$d_1(t) := \int_{t_1}^t (w(s) - v(t_1)) ds, \quad 0 \leq t \leq t_1.$$  

(11.2)
Next define
\[
Z_1(t) = (\Psi_1(y_1, t), \Pi_1(y_1, t), Q(t), P(t)) := (\Psi(y, t), \Pi(y, t), Q(t), P(t))
\]
\[
= (\Psi(y_1 - d(t), t), \Pi(y_1 - d(t), t), Q(t), P(t)).
\] (11.3)

Then we obtain the final form of the “frozen equation” for the transversal dynamics
\[
\dot{Z}_1(t) = A_1 Z_1(t) + B_1(t) Z_1(t) + N_1(t), \quad 0 \leq t \leq t_1,
\] (11.4)
where \(N_1(t) = \tilde{N}(t)\) from the basic equation (6.15) expressed in terms of \(y = y_1 - d(t)\), and
\[
B_1(t) = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & B_v(t) - B_v(t_1) \\
0 & 0 & \langle \nabla(\psi_{v(t)} - \psi_{v(t_1)}), \cdot \nabla \rho \rangle & 0
\end{pmatrix}.
\]

At the end of this section, we will derive appropriate bounds for the “remainder terms” \(B_1(t)Z_1(t)\) and \(N_1(t)\) in (11.4). First, note that we have by Lemma 6.2,
\[
|B_v(t) - B_v(t_1)| \leq \left| \int_t^{t_1} \dot{v}(s) \cdot \nabla_v B_v(s) ds \right| \leq C \int_t^{t_1} \|Z(s)\|^2_{-\beta} ds.
\] (11.5)

Similarly,
\[
|\langle \nabla(\psi_{v(t)} - \psi_{v(t_1)}), \cdot \nabla \rho \rangle| \leq C \int_t^{t_1} \|Z(s)\|^2_{-\beta} ds.
\] (11.6)

Let us recall the following well-known inequality: for any \(\alpha \in \mathbb{R}\)
\[
(1 + |y + x|)^\alpha \leq (1 + |y|)^\alpha (1 + |x|)^|\alpha|, \quad x, y \in \mathbb{R}^3.
\] (11.7)

**Lemma 11.2** [19] Lemma 7.2. For \((\Psi, \Pi, Q, P) \in E_\alpha\) with any \(\alpha \in \mathbb{R}\) the following estimate holds:
\[
\|\Psi(y_1 - d_1), \Pi(y_1 - d_1), Q, P\|_\alpha \leq \|\Psi, \Pi, Q, P\|_\alpha (1 + |d_1|)^|\alpha|, \quad d_1 \in \mathbb{R}^3.
\] (11.8)

**Corollary 11.3** The following bound holds
\[
\|N_1(t)\|_{-\beta} \leq \|Z_1(t)\|^2_{-\beta} (1 + |d_1(t)|)^{3\beta}, \quad 0 \leq t \leq t_1.
\] (11.9)

Indeed, applying the previous lemma twice, once for \(\alpha = \beta\) and once for \(\alpha = -\beta\), we obtain from (6.16) that
\[
\|N_1(t)\|_{-\beta} \leq (1 + |d_1(t)|)^{\beta} \|\tilde{N}(t, Z(t))\|_{-\beta} \leq \|Z(t)\|_{-\beta} (1 + |d_1(t)|)^{3\beta} \|Z_1(t)\|^2_{-\beta}.
\]

**Corollary 11.4** The following bound holds
\[
\|B_1(t)Z_1(t)\|_{-\beta} \leq C \|Z_1(t)\|_{-\beta}^2 \int_t^{t_1} (1 + |d_1(\tau)|)^{2\beta} \|Z_1(\tau)\|^2_{-\beta} d\tau, \quad 0 \leq t \leq t_1.
\] (11.10)

For proof we apply Lemma 11.2 with \(\alpha = -\beta\) to (11.5) and (11.6) and use the fact that \(B_1(t)Z_1(t)\) depends only on the finite-dimensional components of \(Z_1(t)\).
12 Integral Inequality

Recall that $0 < \delta < 1/2$. The equation (11.4) can be written in the integral form:

$$Z_1(t) = e^{A_1 t} Z_1(0) + \int_0^t e^{A_1(t-s)} [B_1 Z_1(s) + N_1(s)] ds, \ 0 \leq t \leq t_1. \quad (12.1)$$

We apply the symplectic orthogonal projection $P_1 := P_{v(t_1)}$ to both sides, and get

$$P_1 Z_1(t) = e^{A_1 t} P_1 Z_1(0) + \int_0^t e^{A_1(t-s)} P_1 [B_1 Z_1(s) + N_1(s)] ds.$$  

We have used here that $P_1$ commutes with the group $e^{A_1 t}$ since the space $Z_1 := P_1 \mathcal{E}$ is invariant with respect to $e^{A_1 t}$, see Remark 6.6. Applying (6.22) we obtain that

$$\|P_1 Z_1(t)\|_{-2-\delta} \leq \frac{C}{(1+t)^{1+\delta}} \|Z_1(0)\|_\beta + C \int_0^t \frac{1}{(1+|t-s|)^{1+\delta}} \|B_1 Z_1(s) + N_1(s)\|_\beta ds,$$  

where $d_1 := \sup_{0 \leq s \leq t_1} |d_1(t)|$. Since $\|Z_1(t)\|_{1+\beta} \leq C(d_1) \|Z(t)\|_{1+\beta}$ by Lemma 11.2 we can rewrite (12.3) as

$$\|P_1 Z_1(t)\|_{-2-\delta} \leq \frac{C(d_1)}{(1+t)^{1+\delta}} \|Z(0)\|_\beta + C(d_1) \int_0^t \frac{1}{(1+|t-s|)^{1+\delta}} \left[ \|Z(s)\|_{-\beta} \int_s^{t_1} \|Z(\tau)\|_{1+\beta}^2 d\tau + \|Z(s)\|_{1+\beta}^2 \right] ds, \ 0 \leq t \leq t_1.$$  

Let us introduce the majorant

$$m(t) := \sup_{s \in [0,t]} (1+s)^{1+\delta} \|Z(s)\|_{-\beta}, \quad t \in [0,t_*). \quad (12.5)$$

To estimate $d_1(t)$ by $m(t)$ we note that

$$w(s) - v(t_1) = w(s) - v(s) + v(s) - v(t_1) = c(s) + \int_s^{t_1} \dot{v}(\tau) d\tau \quad (12.6)$$

by (6.9). Hence, (11.2), Lemma 6.2 and the definition (12.5) imply

$$|d_1(t)| = \left| \int_t^{t_1} (w(s) - v(t_1)) ds \right| \leq \int_t^{t_1} \left( |\dot{c}(s)| + \int_s^{t_1} |\dot{v}(\tau)| d\tau \right) ds$$

$$\leq C m^2(t_1) \int_t^{t_1} \frac{1}{(1+s)^{2+2\delta}} + \int_s^{t_1} \frac{d\tau}{(1+\tau)^{2+2\delta}} ds \leq C m^2(t_1), \quad 0 \leq t \leq t_1. \quad (12.7)$$

We can replace in (12.4) the constants $C(d_1)$ by $C$ if $m(t_1)$ is bounded for $t_1 \geq 0$. In order to do this replacement, we reduce the exit time. Let us denote by $\varepsilon$ a fixed positive number which we will specify below.

**Definition 12.1** $t'_* \text{ is the exit time}$

$$t'_* = \sup \{ t \in [0,t_*) : m(s) \leq \varepsilon, \ 0 \leq s \leq t \}. \quad (12.8)$$

Now (12.4) and (12.7) imply that for $t_1 < t'_*$

$$\|P_1 Z_1(t)\|_{-2-\delta} \leq \frac{C}{(1+t)^{1+\delta}} \|Z(0)\|_\beta + C \int_0^t \frac{1}{(1+|t-s|)^{1+\delta}} \left[ \|Z(s)\|_{-\beta} \int_s^{t_1} \|Z(\tau)\|_{1+\beta}^2 d\tau + \|Z(s)\|_{1+\beta}^2 \right] ds, \ 0 \leq t \leq t_1.$$  

(12.9)
13 Symplectic Orthogonality

Finally, we are going to change \( P_1 Z_1(t) \) by \( Z(t) \) in the left hand side of (12.9). We will prove that it is possible using again that \( d_\beta \ll 1 \) in (2.13) and due to the following important bound:

**Lemma 13.1** For sufficiently small \( \varepsilon > 0 \), we have for \( t_1 < t' \):

\[
\|Z(t)\|_{-2-\delta} \leq C\|P_1 Z_1(t)\|_{-2-\delta}, \quad 0 \leq t \leq t_1,
\]

(13.1)

where \( C \) depends only on \( \rho \) and \( \tilde{v} \).

**Proof** The proof is based on the symplectic orthogonality (6.21), i.e.

\[
\Pi_{v(t)} Z(t) = 0, \quad t \in [0, t_1],
\]

(13.2)

and on the fact that all the spaces \( Z(t) := P_{v(t)} E \) are almost parallel for all \( t \).

Namely, we first note that \( \|Z(t)\|_{-2-\delta} \leq C(\varepsilon)\|Z_1(t)\|_{-2-\delta} \) by Lemma 11.2 since \( |d_1(t)| \leq C\varepsilon^2 \) for \( t \leq t_1 < t'_* \) by (12.7). Therefore, it suffices to prove that

\[
\|Z_1(t)\|_{-2-\delta} \leq 2\|P_1 Z_1(t)\|_{-2-\delta}, \quad 0 \leq t \leq t_1.
\]

(13.3)

This estimate will follow from

\[
\|\Pi_{v_1} Z_1(t)\|_{-2-\delta} \leq \frac{1}{2} \|Z_1(t)\|_{-2-\delta}, \quad 0 \leq t \leq t_1,
\]

(13.4)

since \( P_1 Z_1(t) = Z_1(t) - \Pi_{v_1} Z_1(t) \), where \( v_1 = v(t_1) \). To prove (13.4), we write (13.5) as

\[
\Pi_{v(t),1} Z_1(t) = 0, \quad t \in [0, t_1],
\]

(13.5)

where \( \Pi_{v(t),1} Z_1(t) \) is \( \Pi_{v(t)} Z(t) \) expressed in terms of the variable \( y_1 = y + d_1(t) \). Hence, (13.4) follows from (13.5) if the difference \( \Pi_{v_1} - \Pi_{v(t),1} \) is small uniformly in \( t \), i.e.

\[
\|\Pi_{v_1} - \Pi_{v(t),1}\|_{-2-\delta} \leq \frac{1}{2} \|Z_1(t)\|_{-2-\delta}, \quad 0 \leq t \leq t_1.
\]

(13.6)

It remains to justify (13.6) for a sufficiently small \( \varepsilon > 0 \). In order to prove the bound (13.6), we will need the formula (6.19) and the following relation which follows from (6.19):

\[
\Pi_{v(t)} Z_1(t) = \sum \Pi_{j1}(v(t))\tau_{j,1}(v(t))\Omega(\tau_{j,1}(v(t)), Z_1(t)),
\]

(13.7)

where \( \tau_{j,1}(v(t)) \) are the vectors \( \tau_j(v(t)) \) expressed in the variables \( y_1 \). In detail (cf. (3.3)),

\[
\tau_{j,1}(v) := (-\partial_j \psi_v(y_1 - d_1(t)), -\partial_j \pi_v(y_1 - d_1(t)), e_j, 0), \quad j = 1, 2, 3,
\]

(13.8)

\[
\tau_{j+3,1}(v) := (\partial_{e_j} \psi_v(y_1 - d_1(t)), \partial_{e_j} \pi_v(y_1 - d_1(t)), 0, \partial_{e_j} \pi_v), \quad j = 1, 2, 3,
\]

where \( v = v(t) \). Thus, we have to estimate the difference of

\[
\Pi_{v_1} Z_1(t) = \sum \Pi_{j1}(v(t))\tau_{j,1}(v_1, y_1)\Omega(\tau_{j,1}(v_1, y_1), Z_1(t, y_1))
\]

and

\[
\Pi_{v(t),1} Z_1(t) = \sum \Pi_{j1}(v(t))\tau_{j,1}(v(t), y_1 - d_1(t))\Omega(\tau_{j,1}(v(t), y_1 - d_1(t)), Z_1(t, y_1)).
\]

The estimate is based on the following bounds. First,

\[
|\Pi_{j1}(v(t)) - \Pi_{j1}(v(t_1))| = |\int_t^{t_1} \dot{v}(s) \cdot \nabla_v \Pi_{j1}(v(s))ds| \leq C \int_t^{t_1} |\dot{v}(s)|ds, \quad 0 \leq t \leq t_1,
\]

(13.9)

since \( |\nabla_v \Pi_{j1}(v(s))| \) is uniformly bounded by (6.8). Second,

\[
|\Omega(\tau_{j,1}(v_1, y_1) - \tau_{j,1}(v(t), y_1 - d_1(t)), Z_1(t, y_1))| \leq \|\tau_{j,1}(v_1, y_1) - \tau_{j,1}(v(t), y_1 - d_1(t))\|_{2+\delta} \|Z_1(t, y_1)\|_{-2-\delta}.
\]
Further, since \(|d_1(t)| \leq C\varepsilon^2\) and \(\nabla \tau_j\) are smooth and sufficiently fast decaying at infinity functions, Lemma 11.2 implies
\[
\|\tau_j,1(v(t)) - \tau_j(v(t))\|_{2+\delta} \leq C|d_1(t)| \leq C\varepsilon^2, \quad 0 \leq t \leq t_1
\] (13.10)
for all \(j = 1, 2, \ldots, 6\), where \(C\) depends only on \(\delta\) and \(\bar{u}\). Finally,
\[
\tau_j(v(t)) - \tau_j(v(t_1)) = \int_t^{t_1} \hat{v}(s) \cdot \nabla \tau_j(v(s))\,ds,
\]
and therefore
\[
\|\tau_j(v(t)) - \tau_j(v(t_1))\|_{2+\delta} \leq C \int_t^{t_1} |\hat{v}(s)|\,ds, \quad 0 \leq t \leq t_1.
\] (13.11)
At last, the bounds (13.6) will follow from (6.19), (13.7) and (13.10)-(13.9) if we establish that the integral in the right hand side of (13.11) and (13.9) can be made as small as we please by choosing \(\varepsilon > 0\) sufficiently small. Indeed,
\[
\int_t^{t_1} |\hat{v}(s)|\,ds \leq C m^2(t_1) \int_t^{t_1} ds (1 + s)^{2+2\delta} \leq C\varepsilon^2, \quad 0 \leq t \leq t_1.
\] (13.12)
The proof is complete.

\section{14 Decay of Transversal Component}

Here we complete the proof of Proposition 6.3.

\textbf{Step i}) We fix an \(\varepsilon, 0 < \varepsilon \leq r_\beta(\bar{v})\) and \(t'_\varepsilon(t)\) for which Lemma 13.1 holds. Then the bound of type (12.9) holds with \(\|P_1Z_1(t)\|_{-2-\delta}\) in the left hand side replaced by \(\|Z(t)\|_{-\beta}\):
\[
\|Z(t)\|_{-\beta} \leq C\|Z_1(t)\|_{-2-\delta} \leq C\|P_1Z_1(t)\|_{-2-\delta} \leq \frac{C}{(1 + t)^{1+\tau}}\|Z(0)\|_{\beta}
\]
\[
+ C \int_0^t \frac{1}{(1 + |t - s|)^{1+\delta}} \left[\|Z(s)\|_{-\beta} \int_s^{t_1} \|Z(\tau)\|_{-\beta} d\tau + \|Z(s)\|_{-\beta}^2\right] ds, \quad 0 \leq t \leq t_1
\] (14.1)
for \(t_1 < t'_\varepsilon\). This implies an integral inequality for the majorant \(m(t)\) introduced by (12.5). Namely, multiplying both sides of (14.1) by \((1 + t)^{1+\delta}\), and taking the supremum in \(t \in [0, t_1]\), we get
\[
m(t_1) \leq C\|Z(0)\|_{\beta} + C \sup_{t \in [0, t_1]} \left[\int_0^t \frac{(1 + t)^{1+\delta}}{(1 + |t - s|)^{1+\delta}} \left[\frac{m(s)}{(1 + s)^{1+\delta}} \int_s^{t_1} \frac{m^2(\tau)d\tau}{(1 + \tau)^{2+2\delta}} + \frac{m^2(s)}{(1 + s)^{2+2\delta}}\right] ds\right]
\]
for \(t_1 < t'_\varepsilon\). Taking into account that \(m(t)\) is a monotone increasing function, we get
\[
m(t_1) \leq C\|Z(0)\|_{\beta} + C[m^3(t_1) + m^2(t_1)]I(t_1), \quad t_1 < t'_\varepsilon.
\] (14.2)
where
\[
I(t_1) = \sup_{t \in [0, t_1]} \left[\int_0^t \frac{(1 + t)^{1+\delta}}{(1 + |t - s|)^{1+\delta}} \left[\frac{1}{(1 + s)^{1+\delta}} \int_s^{t_1} \frac{d\tau}{(1 + \tau)^{2+2\delta}} + \frac{1}{(1 + s)^{2+2\delta}}\right] ds\right] \leq \mathcal{T} < \infty, \quad t_1 \geq 0.
\]
Therefore, (14.2) becomes
\[
m(t_1) \leq C\|Z(0)\|_{\beta} + C\mathcal{T}[m^3(t_1) + m^2(t_1)], \quad t_1 < t'_\varepsilon.
\] (14.3)
This inequality implies that \(m(t_1)\) is bounded for \(t_1 < t'_\varepsilon\), and moreover,
\[
m(t_1) \leq C_1\|Z(0)\|_{\beta}, \quad t_1 < t'_\varepsilon,
\] (14.4)
since \(m(0) = \|Z(0)\|_{\beta}\) is sufficiently small by (3.7).

\textbf{Step ii}) The constant \(C_1\) in the estimate (14.4) does not depend on \(t_\varepsilon\) and \(t'_\varepsilon\) by Lemma 13.1. We choose \(d_\beta\) in (2.15) so small that \(\|Z(0)\|_{\beta} < \varepsilon/(2C_1)\). It is possible due to (3.7). Then the estimate (14.4) implies that \(t'_\varepsilon = t_\varepsilon\) and therefore (14.4) holds for all \(t_1 < t_\varepsilon\). Then the bound (12.7) holds for all \(t < t_\varepsilon\). Therefore, (6.4) also holds for all \(t < t_\varepsilon\). Finally, this implies that \(t_\varepsilon = \infty\), hence also \(t'_\varepsilon = \infty\) and (14.4) holds for all \(t_1 > 0\) if \(d_\beta\) is small enough.

The transversal decay (6.13) is proved. \qed
15 Soliton Asymptotics

Here we prove our main Theorem 2.5 relying on the transversal decay (6.13). First we will prove the asymptotics (2.16) for the vector components, and afterwards the asymptotics (2.17) for the fields.

15.1 Asymptotics for the vector components

From (4.3) we have \( \dot{q} = \dot{b} + \dot{Q} \), and from (6.15), (6.16) with \( \beta = 4 + \delta \), and (4.9) it follows that \( \dot{Q} = B_{v(t)}P + \mathcal{O}(\|Z\|^{-\beta}) \). Thus,

\[
\dot{q} = \dot{b} + \dot{Q} = v(t) + \dot{c}(t) + B_{v(t)}P(t) + \mathcal{O}(\|Z\|^{-\beta}).
\]

The equation (6.10) and the estimates (6.11), (6.13) imply

\[
|\dot{c}(t)| + |\dot{v}(t)| \leq \frac{C_1(\rho, \tau, d_\beta)}{(1 + t)^{2+2\delta}}, \quad t \geq 0.
\]

(15.2)

Therefore, \( c(t) = c_+ + \mathcal{O}(t^{-(1+2\delta)}) \) and \( v(t) = v_+ + \mathcal{O}(t^{-(1+2\delta)}) \), \( t \to \infty \). Since \( |P| \leq \|Z\|^{-\beta} \), the estimates (6.13), and (15.2), (15.1) imply that

\[
\dot{q}(t) = v_+ + \mathcal{O}(t^{-1-\delta}).
\]

Similarly,

\[
b(t) = c(t) + \int_0^t v(s)ds = v_+ t + a_+ + \mathcal{O}(t^{-2\delta}),
\]

(15.4)

hence the second part of (2.16) follows:

\[
q(t) = b(t) + Q(t) = v_+ t + a_+ + \mathcal{O}(t^{-2\delta}),
\]

(15.5)

since \( Q(t) = \mathcal{O}(t^{-1-\delta}) \) by (6.13).

15.2 Asymptotics for the fields

We apply the approach developed in [17], see also [15, 16, 18, 21]. For the field part of the solution, \( F(t) = (\psi(x,t), \pi(x,t)) \) let us define the accompanying soliton field as

\[
F_{v(t)}(t) = (\psi_{v(t)}(x - q(t)), \pi_{v(t)}(x - q(t))),
\]

where we define now \( v(t) = \dot{q}(t) \), cf. (15.1). Then for the difference \( Z(t) = F(t) - F_{v(t)}(t) \) we obtain easily the equation [21], Eq. (2.5),

\[
\dot{Z}(t) = AZ(t) - \psi \cdot \nabla \psi F_{v(t)}(t), \quad A(\psi, \pi) = (\pi, \Delta \psi).
\]

Then

\[
Z(t) = W_0(t)Z(0) - \int_0^t W_0(t - s)[\dot{\psi}(s) \cdot \nabla \psi F_{v(s)}(s)]ds.
\]

(15.6)

Since \( \| (\psi_{v_+}, \pi_{v_+})(x - v_+ t - a_+) - F_{v(t)}(t) \|_F = \mathcal{O}(t^{-2\delta}) \) by (15.3) and (15.5), to obtain the asymptotics (2.17) it suffices to prove that \( Z(t) = W_0(t) \Psi_+ + r_+ (t) \) with some \( \Psi_+ \in \mathcal{F} \) and \( \|r_+(t)\|_F = \mathcal{O}(t^{-\delta}) \). This is equivalent to

\[
W_0(-t)Z(t) = \Psi_+ + r'_+(t),
\]

(15.7)

where \( \|r'_+(t)\|_F = \mathcal{O}(t^{-\delta}) \) since \( W_0(t) \) is a unitary group in the Sobolev space \( \mathcal{F} \) by the energy conservation for the free wave equation. Finally, (15.7) holds since (15.6) implies that

\[
W_0(-t)Z(t) = Z(0) + \int_0^t W_0(-s)R(s)ds, \quad R(s) = \dot{\psi}(s) \cdot \nabla \psi F_{v(s)}(s),
\]

(15.8)

where the integral in the right hand side of (15.8) converges in the Hilbert space \( \mathcal{F} \) with the rate \( \mathcal{O}(t^{-\delta}) \). The latter holds since \( \|W_0(-s)R(s)\|_F = \mathcal{O}(s^{-1-\delta}) \) by the unitarity of \( W_0(-s) \) and the decay rate \( \|R(s)\|_F = \mathcal{O}(t^{-\delta}) \).
\( \mathcal{O}(s^{-1-\delta}) \). Let us prove this rate of decay. It suffices to prove that \( |\tilde{v}(s)| = \mathcal{O}(s^{-1-\delta}) \), or equivalently \( |\tilde{\rho}(s)| = \mathcal{O}(s^{-1-\delta}) \). Substitute (4.2) to the last equation of (1.2) and obtain

\[
\dot{\rho}(t) = \int \left[ \psi_{\nu(t)}(x - b(t)) + \Psi(x - b(t), t) \right] \nabla \rho(x - b(t) - Q(t)) \, dx
\]

\[
= \int \psi_{\nu(t)}(y) \nabla \rho(y) \, dy + \int \psi_{\nu(t)}(y) \left[ \nabla \rho(y - Q(t)) - \nabla \rho(y) \right] \, dy + \int \Psi(y, t) \nabla \rho(y - Q(t)) \, dy.
\]

The first integral in the right hand side is zero by the stationary equations (2.3). The second integral is \( \mathcal{O}(t^{-1-\delta}) \), since \( Q(t) = \mathcal{O}(t^{-1-\delta}) \), and by the conditions (1.9) on \( \rho \). Finally, the third integral is \( \mathcal{O}(t^{-1-\delta}) \) by the estimate (6.13). The proof is complete.

**A Structure of the matrix \( M^{-1}(i\omega) \)**

We prove Lemmas 9.3 and 9.5. Recall that for \( \omega \in \mathbb{R} \)

\[
M(i\omega) = \begin{pmatrix} i\omega I_3 & -B_v \\ -F(i\omega) & i\omega I_3 \end{pmatrix},
\]

where

\[
B_v = \begin{pmatrix} \nu^2 & 0 & 0 \\ 0 & \nu & 0 \\ 0 & 0 & \nu \end{pmatrix}, \quad F(i\omega) = \begin{pmatrix} f_1(\omega) & 0 & 0 \\ 0 & f(\omega) & 0 \\ 0 & 0 & f(\omega) \end{pmatrix}.
\]

Here \( f_1(\omega) = F_{11}(i\omega + 0), \ f(\omega) = F_{22}(i\omega + 0) = F_{33}(i\omega + 0) \) with

\[
F_{jj}(\lambda) = \int dk \frac{|\hat{\rho}|^2 k_j^2}{k^2 + (\lambda + ik_1 \nu)^2} - \int dk \frac{|\hat{\rho}|^2 k_j^2}{k^2 - (k_1 \nu)^2}.
\]

(A.1)

\( F_{jj}(\lambda) \) are analytic functions in \( \mathbb{C} \) by Lemma 7.4. Thus,

\[
F_{jj}(\lambda) = F_{jj}(0) + F'_{jj}(0) \lambda + \frac{F''_{jj}(0)}{2} \lambda^2 + \ldots
\]

Here \( F_{jj}(0) = 0 \) by (A.1). Further, by (A.1)

\[
F'_{jj}(\lambda) = -2 \int dk k_j^2 |\hat{\rho}|^2 \frac{\lambda + ik_1 \nu}{(k^2 + (\lambda + ik_1 \nu)^2)^2}
\]

(A.2)

and

\[
F'_{jj}(0) = -2ik \int dk k_j^2 |\hat{\rho}|^2 \frac{k_1}{(k^2 - (k_1 \nu)^2)^2} = 0,
\]

since the integrand function is odd in \( k_1 \). Hence, we obtain \( F_{jj}(\lambda) = \lambda^2 r_j(\lambda) \), where \( r_j(\lambda) \) is analytic in \( \mathbb{C} \). Note that \( r_j(0) = F''_{jj}(0)/2 \). By (A.2) we have

\[
F''_{jj}(\lambda) = -2 \int dk k_j^2 |\hat{\rho}|^2 \frac{k_1^2 - 3(\lambda + ik_1 \nu)^2}{(k^2 + (\lambda + ik_1 \nu)^2)^3}
\]

and finally,

\[
F_{jj}(i\omega) = -\omega^2 r_j(\omega), \quad r_j(0) = - \int dk k_j^2 |\hat{\rho}|^2 \frac{k_1^2 + 3(k_1 \nu)^2}{(k^2 - (k_1 \nu)^2)^3}.
\]

(A.3)

Let us denote \( r(\omega) = r_2(\omega) = r_3(\omega) \). Then

\[
L(\omega) := M^{-1}(i\omega) = \begin{pmatrix} L_{11}(\omega) & L_{12}(\omega) \\ L_{21}(\omega) & L_{22}(\omega) \end{pmatrix},
\]

(A.4)
where
\[
L_{11}(\omega) = \begin{pmatrix}
\frac{-i\omega}{\omega^2 + \nu^2 f_1(\omega)} & 0 & 0 \\
0 & \frac{-i\omega}{\omega^2 + \nu f(\omega)} & 0 \\
0 & 0 & \frac{-i\omega}{\omega^2 + \nu f(\omega)}
\end{pmatrix} = \frac{1}{\omega} \begin{pmatrix}
\frac{-i}{1 - \nu^2 r_1(\omega)} & 0 & 0 \\
0 & \frac{-i}{1 - \nu r(\omega)} & 0 \\
0 & 0 & \frac{-i}{1 - \nu r(\omega)}
\end{pmatrix},
\]
by \((A.3)\); we denote the last matrix \(\mathcal{L}_{11}(\omega)\). Similarly,
\[
L_{12}(\omega) = \begin{pmatrix}
\frac{-\nu^3}{\omega^2 + \nu^2 f_1(\omega)} & 0 & 0 \\
0 & \frac{-\nu}{\omega^2 + \nu f(\omega)} & 0 \\
0 & 0 & \frac{-\nu}{\omega^2 + \nu f(\omega)}
\end{pmatrix} = \frac{1}{\omega^2} \begin{pmatrix}
\frac{-\nu^3}{1 - \nu^2 r_1(\omega)} & 0 & 0 \\
0 & \frac{-\nu}{1 - \nu r(\omega)} & 0 \\
0 & 0 & \frac{-\nu}{1 - \nu r(\omega)}
\end{pmatrix},
\]
we denote the last matrix \(\mathcal{L}_{12}(\omega)\). Note that
\[
\mathcal{L}_{11}(\omega) = i\mathcal{L}_{12}(\omega)B_v^{-1}.
\]
Further,
\[
L_{21} = \begin{pmatrix}
\frac{-f_1(\omega)}{\omega^2 + \nu^2 f_1(\omega)} & 0 & 0 \\
0 & \frac{-f(\omega)}{\omega^2 + \nu f(\omega)} & 0 \\
0 & 0 & \frac{-f(\omega)}{\omega^2 + \nu f(\omega)}
\end{pmatrix} = \begin{pmatrix}
\frac{r_1(\omega)}{1 - \nu^2 r_1(\omega)} & 0 & 0 \\
0 & \frac{r(\omega)}{1 - \nu r(\omega)} & 0 \\
0 & 0 & \frac{r(\omega)}{1 - \nu r(\omega)}
\end{pmatrix},
\]
so we put \(L_{21} = L_{21}\). Finally,
\[
L_{22}(\omega) = L_{11}(\omega) = \frac{1}{\omega} \mathcal{L}_{11}(\omega),
\]
and thus, \(L_{22}(\omega) = L_{11}(\omega)\). Note that the denominators of the matrix elements of each matrix \(\mathcal{L}_{11}\) to \(\mathcal{L}_{22}\) are nonzero at \(\omega = 0\), since \(r_1(0) < 0\) and \(r(0) < 0\) by \((A.3)\). For \(\omega \neq 0\) the denominators are nonzero by Lemma \(8.2\). This completes the proof of Lemma \(9.3\). Finally, \((A.4)\) to \((A.8)\) imply Lemma \(9.3\) since \(r_j(\omega) = -F_{jj}(\omega)/\omega^2\), where \(F_{jj}(\omega)\) are bounded functions by \((7.25)\).

**B Symplectic orthogonality conditions**

Let us check that the symplectic orthogonality conditions \((9.13)\) with \(j = 1, 2, 3\) read the first equation of \((9.19)\). By \((7.8)\),
\[
\Phi(\Psi_0, \Pi_0)(0) = i\langle kv\hat{\Psi}_0 + \hat{\Pi}_0, \frac{k\hat{\rho}}{D(0)} \rangle, \quad \hat{D}(0) = k^2 - (kv)^2.
\]
On the other hand, by \((9.13)\) with \(j = 1, 2, 3\), and \((3.3), (2.10)\), we have
\[
0 = \Omega(X_0, \tau_j) = -\langle \Psi_0, \partial_j \pi_v \rangle + \langle \Pi_0, \partial_j \psi_v \rangle - P_0 \cdot e_j = \langle \hat{\Psi}_0, \frac{k_j k v \hat{\rho}}{D(0)} \rangle + \langle \hat{\Pi}_0, \frac{ik_j \hat{\rho}}{D(0)} \rangle - P_0 \cdot e_j
\]
\[
= \langle kv\hat{\Psi}_0, \frac{k_j \hat{\rho}}{D(0)} \rangle - i\langle \Pi_0, \frac{k_j \hat{\rho}}{D(0)} \rangle - (P_0)_j = -\Phi_j(\Psi_0, \Pi_0)(0) - (P_0)_j.
\]
Now let us check that the conditions \((9.13)\) with \(j = 4, 5, 6\) read the second equation of \((9.19)\). By \((7.8)\)
\[
\Phi'(0) = i\langle \hat{\Psi}_0, k\hat{\rho} \rangle - i\langle 2ikv \hat{\Psi}_0 + \hat{\Pi}_0, \frac{k\hat{\rho}}{D^2(0)} \rangle = \langle \frac{(k^2 + (kv)^2)i\hat{\Psi}_0 + 2kv\Pi_0}{(k^2 - (kv)^2)}, k\hat{\rho} \rangle,
\]
where the integral converges by the condition (1.11). On the other hand, by (9.13) with \( j = 4, 5, 6 \), and (3.3), (2.10), we have for \( j = 1, 2, 3 \)

\[
0 = \Omega(\tau_{3+j}) = \langle \hat{\Psi}_0, \partial_{v_j} \pi_v \rangle - \langle \hat{\Pi}_0, \partial_{v_j} \psi_v \rangle + Q_0 \cdot \partial_{v_j} p_v \\
= \langle \hat{\Psi}_0, -ik_j \frac{k^2 + (kv)^2}{D^2(0)} \hat{\rho} \rangle + \langle \hat{\Pi}_0, 2k_j \frac{k v \hat{\rho}}{D^2(0)} \rangle + Q_0 \cdot \partial_{v_j} p_v = \Phi_j'(0) + (B_v^{-1}Q_0)_j,
\]

since \( Q_0 \cdot \partial_{v_j} p_v = Q_0 \cdot B_v^{-1} e_j = B_v^{-1}Q_0 \cdot e_j \).
