Abstract. Rho-like GTPases, including Cdc42, Rac, and Rho, regulate signaling pathways that control actin cytoskeletal structures and transcriptional activation. The Tiam1 gene encodes an activator of Rac1, and similarly to constitutively activated (V12)Rac1, overexpression of Tiam1 in fibroblasts induces the formation of membrane ruffles. Tiam1 contains a Dbl homology (DH) domain and adjacent pleckstrin homology (PH) domain, hallmarks for activators of Rho-like GTPases. Unique for Tiam1 are an additional PH domain and a Disc-large homology region in the NH$_2$-terminal part of the protein. Here we show that both in fibroblasts and COS cells, membrane localization of Tiam1 is required for the induction of membrane ruffling. A detailed mutational analysis, in combination with confocal laser scanning microscopy and immunoelectron microscopy, demonstrates that the NH$_2$-terminal PH domain of Tiam1, but not the DH-adjacent PH domain, is essential for membrane association. This NH$_2$-terminal PH domain of Tiam1 can be functionally replaced by the myristoylated membrane localization domain of c-Src, indicating that the primary function of this PH domain is to localize the protein at the membrane. After serum starvation, both membrane association of Tiam1 and ruffling can be induced by serum, suggesting that receptor stimulation induces membrane translocation of Tiam1. Similar to V12Rac1, Tiam1 stimulates the activity of the c-Jun NH$_2$-terminal kinase (JNK). This Rac-dependent stimulation of JNK also requires membrane association of Tiam1. We conclude that the regulated membrane localization of Tiam1 through its NH$_2$-terminal PH domain determines the activation of distinct Rac-mediated signaling pathways.

Rho-like GTPases, which include Cdc42, Rac1, and RhoA, control distinct signal transduction pathways that determine the organization of the actin cytoskeleton in response to various extracellular stimuli. In fibroblast cells, activation of Cdc42 and Rac results in the formation of focal complexes and filopodia or lamellipodia, respectively, while Rho is involved in the formation of stress fibers and focal contacts (Ridley and Hall, 1992; Ridley et al., 1992; Kozma et al., 1995; Nobes and Hall, 1995a). Each of these GTPases can be activated by specific growth factors, and they may also constitute a hierarchical signaling cascade (Kozma et al., 1995; Nobes and Hall, 1995a). The resulting cytoskeletal rearrangements influence both adhesion and motility of cells, implicating Rho-like GTPases as key regulators of these processes (Nobes and Hall, 1995b).

Apart from their effects on the cytoskeleton, both Cdc42 and Rac1 can activate the c-Jun NH$_2$-terminal kinase (JNK)$^1$ pathway, while all three Rho-like GTPases activate serum response factor (Cosentino et al., 1995; Hill et al., 1995; Minden et al., 1995; Olson et al., 1995). Rho-like proteins thus may also play a role in transcriptional activation of genes. Moreover, both Rac1 and RhoA are involved in the transformation of cells by Ras (Khosravi-Far et al., 1995; Qiu et al., 1995a, b), and constitutively active mutants of Rac1

---

1. Abbreviations used in this paper: aa, amino acids; DH, Dbl homology; DHR, Discs-large homology region; GDI, guanine nucleotide dissociation inhibitors; GDS, guanine nucleotide dissociation stimulator; GRF, guanine nucleotide release factor; GST, glutathione S-transferase; HA, hemagglutinin; IP$_3$, inositol (3,4,5)trisphosphate; JNK, c-Jun NH$_2$-terminal kinase; MAPK, mitogen-activated protein kinase; PH, pleckstrin homology; PIP2 and PIP3, phosphatidylinositol (4,5)bisphtate and (3,4,5)trisphosphate.
(V12Rac1) and RhoA (V14RhoA) can induce an oncogenic phenotype in NIH3T3 cells (Perona et al., 1993; Qiu et al., 1995a; Van Leeuwen et al., 1995).

Rho-like GTPases are activated by guanine nucleotide dissociation stimulators (GDSs), also known as guanine nucleotide exchange factors. Inactivation occurs by hydrolysis of bound GTP, which is stimulated by interaction with GTPase activating proteins, while guanine nucleotide dissociation inhibitors (GDIs) lock the GTPases either in the active or in the inactive state (Boguski and McCormick, 1993). The role of these regulators in the diverse signaling pathways mediated by Rho-like proteins is largely unknown.

**Tiam1** was originally identified in T-lymphoma cells as an invasion- and metastasis-inducing gene (Habets et al., 1994). The predicted Tiam1 protein consists of 1,591 amino acids and contains a Dbl homology (DH) domain. This domain is present in GDS proteins for Rho-like GTPases and is considered to be the catalytic domain (Hart et al., 1994). DH domains are found in a rapidly expanding group of proteins, many of which are encoded by transforming genes that were identified after transfection of genomic DNA or cDNA libraries into NIH3T3 cells (Cerione and Zheng, 1996; Collard, 1996). A number of these proteins, like Dbl, Ost, Cdc24, Lbc, and Vav were shown to activate Rho-like GTPases (Hart et al., 1991; Horii et al., 1994; Zheng et al., 1994, 1995; Olson et al., 1996). Tiam1 is the only GDS protein identified that specifically activates Rac in vitro as well as in vivo (Michiels et al., 1995). In fibroblasts, Tiam1 induces the formation of membrane ruffles, similarly to constitutively activated V12Rac1 (Michiels et al., 1995). The Tiam1-induced phenotype is inhibited by coexpression of dominant-negative mutant (N17)Rac1, but not by coexpression of (N17)Cdc42 or by inactivation of RhoA with C3 transferase (Michiels et al., 1995; Collard, 1996). This indicates that the Tiam1-induced membrane ruffling is primarily caused by activation of Rac and that other Rho-like GTPases are not involved. Moreover, V12Rac1, but not V14RhoA, induces an invasive phenotype in T-lymphoma cells, similar to Tiam1, suggesting that Tiam1-induced invasiveness is also caused by activation of Rac (Michiels et al., 1995).

Apart from the DH domain, Tiam1 contains several other conserved motifs, including a consensus myristoylation sequence at the NH2 terminus, a Discs-large homology region (DHRR), and two pleckstrin homology (PH) domains (Habets et al., 1994; Collard, 1996; see Fig. 1A). One of the PH domains is present COOH-terminally adjacent to the DH domain, as found in all other GDS proteins for Rho-like GTPases (Collard, 1996), while a second PH domain is located in the NH2-terminal part of Tiam1. DHR domains have been implicated as protein–protein interaction motifs (Ponting and Phillips, 1995). PH domains, primarily found in signaling molecules, are thought to determine the cellular localization and/or activity of these proteins by interacting with proteins or phospholipids (for review see Lemmon et al., 1996).

Since little is known of the intracellular localization and requirements of GDS proteins to stimulate Rho-like GTPases, we analyzed the conditions for Tiam1 to stimulate Rac-dependent membrane ruffling and JNK activity. For this, truncated Tiam1 proteins, or proteins that contain small deletions in each of the conserved domains, were expressed in fibroblast cells and COS cells, and their intracellular localization and biological activity were analyzed by confocal microscopy, immunoelectron microscopy, and analysis of JNK activity. We demonstrate that membrane association of Tiam1 is absolutely required for Rac-dependent induction of membrane ruffling and stimulation of JNK activity. Membrane association of Tiam1 is accomplished through the NH2-terminal PH domain, but not the COOH-terminal PH domain or the DHR domain. Moreover, PH domain–dependent membrane association of Tiam1 could be induced by serum. These results suggest that the controlled membrane association of Tiam1 is an important factor in the activation of distinct Rac-mediated signaling pathways.

**Materials and Methods**

**Transfection Constructs**

Full-length mouse Tiam1 (FL1591) and the NH2-terminally truncated C1199 and CS80 Tiam1 constructs (nomenclature refers to the number of COOH-terminal amino acids [aa] of the encoded Tiam1 proteins) contain artificial SpeI and SalI restriction sites in front of the first ATG and a hemagglutinin tag (HA-tag), followed by a SalI restriction site, at their 3' ends. They were cloned as SpeI-SalI fragments into the eukaryotic expression vector pUTSV1 (Eurogentec S.A., Belgium), which was linearized by SpeI and Xhol. C1199-ΔPHc carries a small internal PstI (aa 1377) to BsmI (aa 1390) deletion in the conserved COOH-terminal part of the DH-adjacent PH domain. C1199-ΔDH1 carries a BamHI (aa 1103) to XbaI (aa 1130) deletion in a nonconserved part of the DH domain. C1199-ΔDHRR carries a large NotI (aa 853) to Asp718 (aa 905) deletion in the DHR region that eliminates most of the DHR region. C1199-ΔPHn carries a small internal Asp700 (aa 513) to EarI (aa 528) deletion in the conserved COOH-terminal part of the NH2-terminal PH domain, which is quite similar to the deletion made in the COOH-terminal PH domain (C1199-ΔPHc). Overhangs were blunted by either Klenow end filling reactions (Boehringer Mannheim Corp., Indianapolis, IN) or with T4 DNA polymerase (Boehringer Mannheim Corp.) before ligation. The myristoylation sequence of c-Src, encoding the NH2-terminal 20 amino acids, was amplified with SpeI-SalI adaptors by PCR with Pfu polymerase (Stratagene, La Jolla, CA) and cloned between the SpeI and SalI sites at the 5' ends of the FL1591-ΔPHn, C1191-ΔPHn, and CS80 Tiam1 constructs. Fragments containing the COOH-terminal PH domain of Tiam1, the PH domain of Dbl, or the PH domain of β-Ark were amplified by PCR with Smal and PvuII adaptors and used to replace the region containing the NH2-terminal PH domain of Tiam1 in the C1199 construct. The exchanged regions contain 17 additional aa at the NH2-terminal end and 36 additional aa (33 aa for β-Ark) at the COOH-terminal end, in comparison to the consensus PH domain (Gibson et al., 1994). To analyze whether the NH2-terminal PH domain is sufficient for membrane targeting, a region containing the NH2-terminal PH domain, from Sall (aa 393) to BstXI (aa 647), was fused to the Bsu36I site (aa 1022) at the NH2 terminus of the CS80 Tiam1 protein. All amplified fragments were sequenced with the T7 polymerase sequencing kit (Pharmacia LKB Biotechnology Inc., Uppsala, Sweden).

**Cells and Transfection Experiments**

NIH3T3 cells, stably expressing the C1199 Tiam1 protein and C682 Tiam1 protein, have been described previously (Van Leeuwen et al., 1995). NIH3T3 cells and COS-7 cells were cultured in a humidified CO2 incubator in DME supplemented with 10% newborn calf serum or 10% fetal calf serum, respectively. For transient expression assays, NIH3T3 cells were seeded in dishes with or without coverslips (8,000 cells/cm2), 18 h after seeding, cells were transfected with lipofectamin (Life Technologies, Inc., Grand Island, NY). COS-7 cells were seeded in dishes with or without coverslips and transfected using DEAE dextran (Seed and Aruffo, 1987). 16 h after transfection, the medium was either replaced and cells were incubated for an additional 30 h before washing and fixation, or cells were incubated for 24 h in serum-free medium, followed by the addition of serum for 2 h. Western blot analyses were performed to monitor the size.
Membrane Association of Tiam1 Is Required for Membrane Ruffling

We have shown previously that full-length Tiam1 (FL1591) or a large COOH-terminal fragment of the Tiam1 protein (C1199) causes Rac1-dependent induction of membrane ruffling in NIH3T3 fibroblast cells (Michiels et al., 1995). Established NIH3T3 cell lines expressing either of these proteins are flat and epithelial-like and contain many membrane ruffles (Fig. 1 B), a phenotype that is also induced by transfection or microinjection of constitutively activated (V12)Rac1 (Ridley et al., 1992; Michiels et al., 1995; Van Leeuwen et al., 1995). In contrast, a smaller COOH-terminal part of the Tiam1 protein (C682), which contains only the DH domain and the adjacent PH domain, did not induce this phenotype (Fig. 1 C). As shown by confocal laser scanning immunofluorescence microscopy, the truncated large C1199 Tiam1 protein was present in the cytoplasm and colocalized with F-actin in membrane ruffles (Fig. 1 B). In contrast, the short C682 Tiam1 protein seemed to be restricted to the cytoplasm (Fig. 1 C). Western blot analyses (see Fig. 4, lanes I–3) indicated that both proteins were intact and equally expressed. This suggested that the difference in phenotypes induced by these truncated proteins is probably caused by a different intracellular localization, and not by differences in stability. Immunoelectron microscopy (immuno-EM) indeed confirmed that the C1199 protein is restricted to the cytoplasm, whereas the C682 protein is also present in membrane ruffles.

**Results**

**Membrane Association of Tiam1 Is Required for Membrane Ruffling**

We have shown previously that full-length Tiam1 (FL1591) or a large COOH-terminal fragment of the Tiam1 protein (C1199) causes Rac1-dependent induction of membrane ruffling in NIH3T3 fibroblast cells (Michiels et al., 1995). Established NIH3T3 cell lines expressing either of these proteins are flat and epithelial-like and contain many membrane ruffles (Fig. 1 B), a phenotype that is also induced by transfection or microinjection of constitutively activated (V12)Rac1 (Ridley et al., 1992; Michiels et al., 1995; Van Leeuwen et al., 1995). In contrast, a smaller COOH-terminal part of the Tiam1 protein (C682), which contains only the DH domain and the adjacent PH domain, did not induce this phenotype (Fig. 1 C). As shown by confocal laser scanning immunofluorescence microscopy, the truncated large C1199 Tiam1 protein was present in the cytoplasm and colocalized with F-actin in membrane ruffles (Fig. 1 B). In contrast, the short C682 Tiam1 protein seemed to be restricted to the cytoplasm (Fig. 1 C). Western blot analyses (see Fig. 4, lanes I–3) indicated that both proteins were intact and equally expressed. This suggested that the difference in phenotypes induced by these truncated proteins is probably caused by a different intracellular localization, and not by differences in stability. Immunoelectron microscopy (immuno-EM) indeed confirmed that the C1199 protein is restricted to the cytoplasm, whereas the C682 protein is also present in membrane ruffles.

**Figure 1.** Confocal images of NIH3T3 cells expressing truncated Tiam1 proteins. A depicts the Tiam1 constructs encoding the COOH-terminal 1,199 amino acids (C1199) or 682 amino acids (C682) that were used for transfection of NIH3T3 cells, in comparison to the full-length Tiam1 protein (FL1591). Established cell lines that express the C1199 Tiam1 protein (B) or the C682 Tiam1 protein (C) were fixed and stained with anti-Tiam1 antibodies (Habets et al., 1994), followed by FITC-coupled secondary antibodies (left) and by TRITC-labeled phalloidin for F-actin (right). Note the prominent membrane ruffling in cells that express the C1199 Tiam1 protein. Stress fibers are hardly visible in these cells, since the optical sections were made through the upper half of the cells to reveal the presence or absence of membrane ruffling. No significant differences were found in the amount or appearance of stress fibers between Tiam1-expressing cells and controls. M, myristoylation signal; P, PEST regions; PHn and PHc, NH2-terminal and COOH-terminal pleckstrin homology domains. Magnification is 250×. Bar, 40 μm.
Tiam1 protein is present in the cytoplasm as well as at the cell membrane and particularly in the membrane ruffles, whereas the C682 Tiam1 protein is almost exclusively located in the cytoplasm (Fig. 2). We hypothesized, therefore, that membrane localization of Tiam1 is required for morphological transformation of NIH3T3 cells, including the formation of membrane ruffles.

**The NH₂-terminal PH Domain Is Essential for Membrane Localization of Tiam1**

To investigate which of the conserved domains in Tiam1 determines the intracellular localization, small deletions were made in each of these domains within the C1199 construct (see Fig. 3 and Materials and Methods). These mutant proteins were transiently expressed in COS-7 cells to analyze their intracellular localization and ability to induce membrane ruffling. Transfection of these mutant Tiam1 constructs in NIH3T3 cells resulted in the same phenotypic changes (not shown). Although Tiam1 is endogenously expressed in COS-7 cells and NIH3T3 cells, the levels are too low to be visualized by immunocytochemistry or Western blotting. If phenotypic changes were induced by the transfection of Tiam1 mutants, they were found in >80% of the transfected cells.

As shown in Fig. 3 B, the C1199 Tiam1 protein carrying a small internal deletion in the conserved COOH-terminal part of the DH-adjacent PH domain (C1199-ΔPHc) was still able to induce membrane ruffling. This was an unexpected finding since deletions in the DH-adjacent PH domain of other GDS proteins interfered with their proper functioning (Hart et al., 1994; Whitehead et al., 1995b), and mutations in this region of the PH domain of β-Ark abolished interactions with both Gp[subscript γ] proteins and phospholipids (Touhara et al., 1995). In contrast, a C1199 Tiam1 protein with a deletion in the DH domain (C1199-ΔDH) did not induce membrane ruffling (Fig. 3 C), corroborating a previously proposed catalytic function for the DH domain (Hart et al., 1994). Deletion of most of the DHR region (C1199-ΔDHR) did not affect ruffling (Fig. 3 D), indicating that the DHR domain is not required for the induction of membrane ruffles. However, a small deletion in the NH₂-terminal PH domain (C1199-ΔPHn), comparable to the deletion made in the COOH-terminal PH domain, completely abolished membrane ruffling (Fig. 3 E). Western blot analyses showed that all mutant proteins were of the predicted size and expressed at similar levels (see Fig. 4, lanes 4–9), although somewhat less than the C1199 Tiam1 protein. This excludes the possibility that these results were due to major differences in protein stability. We conclude that both the catalytic DH domain and the NH₂-terminal PH domain are essential for Tiam1-induced membrane ruffling.

Immuno-EM analyses of transfected COS cells showed that all mutant proteins were equally present in the cytoplasm and at the plasma membrane (Fig. 5), except for mutant C1199 Tiam1, which contains a deletion in the NH₂-terminal PH domain (C1199-ΔPHn). This protein was almost exclusively localized in the cytoplasm (Fig. 5 D), similar to the C682 Tiam1 protein (Fig. 2 B). The C1199-ΔDH Tiam1 protein, which carries a deletion in the catalytic DH domain and does not induce membrane ruffling, was still capable of associating with the plasma membrane (Fig. 5 B). This clearly shows that membrane localization of Tiam1 is not a consequence of the induction of membrane ruffling. Therefore, it can be concluded that the NH₂-terminal PH domain is essential for the membrane localization of C1199 Tiam1 and that this membrane localization is required for the formation of membrane ruffles.

**The NH₂-terminal PH Domain of Tiam1 Can Be Functionally Replaced by the c-Src Membrane Localization Domain, but Not by Other PH Domains**

To determine whether membrane localization is the only function of the NH₂-terminal PH domain, we fused the NH₂-terminal 20 amino acids of c-Src, containing the myristoylation site and a basic region, in front of a C580 Tiam1 protein, resulting in M⁸-C580 Tiam1 (see Materials and Methods). C580 Tiam1 encompasses the COOH-terminal 580 amino acids and encodes the DH domain and adjacent PH domain (Fig. 6 A). Similar to the C682 Tiam1 protein (see Fig. 2 B), the C580 Tiam1 protein did not induce membrane ruffling and was not localized at the plasma membrane (Figs. 6 A and 7 A). In contrast, the M⁸-C580 Tiam1 protein induced ruffling in both NIH3T3 cells and
COS-7 cells (Fig. 6 B), albeit less extensively than C1199 Tiam1 (Fig. 3 A). No differences were observed in the expression levels of these proteins (Fig. 4, lanes 10–12). Immuno-EM showed that M^5^-CS80 Tiam1 was able to associate with the plasma membrane (Fig. 7 B), although this protein seemed to be more interiorly located than the mutant C1199 Tiam1 proteins (compare Figs. 5 and 7 B). Furthermore, part of the expressed M^5^-CS80 Tiam1 protein was present around vesicle-like structures in the cytoplasm, similar to other M^5^-containing Tiam1 fusion proteins (see for example Fig. 6 E, inset). A fusion protein containing the NH₂-terminal Src domain in front of the C1199-ΔPHn Tiam1 protein was also able to localize at the plasma membrane and to cause ruffling (data not shown). The Src membrane localization domain thus enables C580 Tiam1 and C1199-ΔPHn to induce membrane ruffling by tethering these proteins to the plasma membrane.

To test whether the NH₂-terminal PH domain of Tiam1 is sufficient for membrane localization, we fused a region containing this PH domain to the CS80 Tiam1 protein (see Materials and Methods). The resulting protein, however, did not induce membrane ruffling and was not associated with the plasma membrane (Michiels, F., and J.C. Stam, unpublished results). This might argue that additional sequences are required to ensure membrane localization. Alternatively, the juxtaposition of the PH domain to the DH domain might interfere with the proper folding of these domains. A construct expressing solely the region containing the NH₂-terminal PH domain did not function as a dominant-negative Tiam1 mutant. However, C1199-ΔDH,
which contains a deletion in the catalytic DH domain, also does not interfere with the induction of membrane ruffling by Tiam1. The reason for this is not clear at the moment.

To analyze the specificity of the NH₂-terminal PH domain of Tiam1, a region containing this PH domain was exchanged for the corresponding regions containing the PH domain of DbL, the PH domain of β-ARK, or the COOH-terminal PH domain of Tiam1 (see Materials and Methods). However, none of these mutant Tiam1 proteins localized at the plasma membrane and induced membrane ruffling (data not shown). This means either that additional sequences are required for correct functioning of these PH domains or that the primary function of the NH₂-terminal PH domain, namely to localize Tiam1 through specific interactions with components of the plasma membrane, cannot be substituted for by other PH domains.

The NH₂-terminal PH Domain Is Required for the Induction of Membrane Ruffles by the Full-Length Tiam1 Protein

The full-length Tiam1 protein (FL1591) carries a consensus myristoylation sequence at the NH₂ terminus. By labeling with [³H]myristate, we have confirmed that the NH₂ terminus of Tiam1 is myristoylated (not shown). To test whether the myristoylation is sufficient for the membrane association of full-length Tiam1, a small deletion was also made in the NH₂-terminal PH domain of full-length FL1591.

Figure 4. Immunoblotting of mutant Tiam1 proteins. Cell lysates were separated on a 7.5% SDS-polyacrylamide gel and blotted to nitrocellulose. All mutant C1199 and C682 Tiam1 proteins were detected with a polyclonal anti-Tiam1 antibody (Habets et al., 1994). Mutant C580 Tiam1 proteins were detected with a monoclonal antibody against the HA-tag (12CA5). Proteins were visualized using enhanced chemiluminescence (Amersham Corp.). Molecular mass markers (in kD) are shown. The arrow indicates the position of the mutant C1199 Tiam1 proteins.

Figure 5. Ultrastructural localization of mutant C1199 Tiam1 proteins in COS-7 cells. Immunogold labeling of mutant C1199 Tiam1 proteins with a deletion in the COOH-terminal PH domain (A), a deletion in the DH domain (B), a deletion in the DHR domain (C), and a deletion in the NH₂-terminal PH domain (D). C1199-ΔPHn Tiam1 is almost exclusively localized in the cytoplasm, while other mutant Tiam1 proteins also associate with the plasma membrane. Bar, 400 nm.
Tiam1. However, similar to C1199-ΔPHn, mutant full-length Tiam1 (FL1591-ΔPHn) was unable to induce membrane ruffling in NIH3T3 cells or COS cells (Fig. 6, C and D), and immuno-EM showed that the protein was not localized at the plasma membrane (data not shown). Apparently, the NH2-terminal myristoylation of full-length Tiam1 alone is not sufficient for membrane localization. To further substantiate this, the NH2-terminal c-Src sequences were fused in front of the FL1591-ΔPHn Tiam1 protein. This region of Src contains a basic region that is required for optimal membrane translocation in addition to the myristoylation sequence, whereas other Src-like tyrosine kinases contain a palmitoylated cysteine in this region (Superti-Furga and Courtneidge, 1995). Both additional sequences are absent in Tiam1. Cells expressing the M5-FL1591-ΔPHn1 Tiam1 protein again showed membrane ruffling, although less extensive than cells expressing FL1591 Tiam1 (Fig. 6, C–E). Again, no main differences in expression levels were observed between these proteins (data not shown). Immuno-EM confirmed that the M5-FL1591-ΔPHn1 Tiam1 protein was present at and close to the plasma membrane, as found for M5-CS80 Tiam1 (data not shown). Apparently, the accessory basic region of c-Src also functions to properly localize M5-FL1591-ΔPHn1 Tiam1. Similar to M5-CS80, the expression of M5-FL1591-ΔPHn1 Tiam1 led to the formation of small cytoplasmic vesicle-like structures, and the protein was also located around these structures (Fig. 6 E). These observa-

Figure 6. Confocal images of COS-7 cells expressing mutant Tiam1 proteins. Confocal laser scanning microscopic images of COS-7 cells expressing CS80 Tiam1 (A), M5-CS80 Tiam1 (B), full-length Tiam1 (FL1591) (C), full-length Tiam1 with a deletion in the NH2-terminal PH domain (FL-ΔPHn) (D), and FL-ΔPHn containing a Src myristoylation signal at the NH2 terminus (M5-FL-ΔPHn) (E). The insert in E is a higher magnification of the framed region showing the vesicle-like structures that are surrounded by the M5-FL-ΔPHn Tiam1 protein. Indicated in blue is the myristoylation signal from c-Src (M5), containing the NH2-terminal 20 amino acids. In the merged images, Tiam1 is shown in green and F-actin in red. Magnification is 200×. Bar, 40 μm.
tions indicate that the NH₂-terminal PH domain also serves as an essential membrane tag, or perhaps membrane anchor, for full-length Tiam1.

Controlled Cellular Localization of Tiam1

PH domains have been identified in other signaling molecules as protein–protein and/or protein–phospholipid interaction motifs that are required for the controlled targeting of these proteins to the plasma membrane (Lemmon et al., 1996). In tissue sections of skin and certain carcinomas, endogenous Tiam1 is predominantly present in the cytoplasm. Also in some cell lines, where we can envision endogenous Tiam1 by Western blotting, including T-lymphoma cells and neuronal cells, it is mainly localized in the cytoplasmic fraction (data not shown), suggesting that Tiam1 may translocate to the plasma membrane after receptor stimulation. So far, however, we have not been able to identify a receptor-mediated signaling pathway involving Tiam1 activation. To investigate whether membrane translocation of exogenous Tiam1 could be visualized in NIH3T3 cells, we analyzed whether serum could affect the localization and capacity of Tiam1 to induce membrane ruffling. As shown in Fig. 8 A, NIH3T3 cells transiently expressing the C1199 Tiam1 protein showed no membrane ruffling after serum starvation for 24 h. Almost no Tiam1 protein was present at the plasma membrane, and F-actin was mostly concentrated in lamellipodia in the Tiam1-expressing cells. Since these optical sections were taken at the basal site of the cells to illustrate the lamellipodia, stress fibers are also visible. Note that after serum starvation for 24 h, NIH3T3 cells still contain some stress fibers, in contrast to Swiss 3T3 cells. Immuno-EM confirmed that most of the cells contained significantly less Tiam1 at the plasma membrane after serum starvation (Fig. 8, D and F). The residual membrane-associated Tiam1 might be sufficient for the presence of lamellipodia under these conditions. Addition of serum induced membrane localization and subsequent ruffling of C1199 Tiam1-expressing cells after 2 h (Fig. 8, B and E), at which time point serum-induced stress fibers have already decreased. A quantification of these results is presented in Fig. 8 F. Similar results were obtained with FL1591 Tiam1, C1199-ΔPHc, and C1199-ΔDHR Tiam1 (data not shown). In contrast, after 24 h of serum starvation the M⁵-C580 Tiam1 protein remained at the plasma membrane and still induced membrane ruffling (Fig. 8 C). This suggests that the serum-induced membrane translocation of Tiam1 is mediated by the NH₂-terminal PH domain.

Unexpectedly, neither PDGF nor insulin could substitute for serum in the induction of membrane ruffling (data not shown). Both growth factors induce lamellipodia formation in NIH3T3 cells within 5 min, which can easily be discriminated from the Tiam1-induced ruffling. This might indicate that Tiam1 is not activated by PDGF or insulin.

Membrane-associated Tiam1 Activates JNK

To investigate whether membrane association of Tiam1 is also required for the induction of other Rac-mediated signaling pathways besides membrane ruffling, the activity of JNK was determined after cotransfection with different Tiam1 mutants (see Materials and Methods). Both in COS-7 cells and NIH3T3 cells, cotransfection of full-length Tiam1 led to an almost sevenfold stimulation of JNK activity, similar to constitutively activated (V12)Rac1 (Fig. 9 A). Cotransfection of tagged mitogen-activated protein kinase (MAPK) with full-length or mutant Tiam1 or (V12)Rac did not result in activation of MAPK (not shown). The stimulation of JNK by Tiam1 was dependent on the activation of Rac, since cotransfection of dominant-negative (N17)Cdc42 partly blocked the activation of JNK by Tiam1 (Fig. 9 A). Higher amounts of (N17)Rac interfered with the expression of JNK. Furthermore, a deletion in the catalytic DH domain of Tiam1 prevented JNK activation (not shown). Cotransfection of dominant-negative (N17)Cdc42 did not interfere with the activation of JNK by Tiam1 (data not shown). Transfection of C1199 Tiam1 stimulated JNK activity to a similar extent as FL1591 (Fig. 9 B). However, shorter COOH-terminal Tiam1 fragments such as C682 and C580 Tiam1, which did not localize to the plasma membrane, were not able to activate JNK above background levels. Also, mutant C1199-ΔPHn Tiam1, which did not localize to the plasma membrane because of the deletion in the NH₂-terminal PH domain, was unable to activate JNK (Fig. 9 B). M⁵-C580 Tiam1 caused no stimulation of JNK activity (Fig. 9 B), and neither did M⁵-C1199-ΔPHn or M⁵-FL1591-ΔPHn Tiam1 proteins (data not shown). These proteins, however, induced membrane ruffling and were present at the plasma membrane (Fig.
A possible explanation for this somewhat unexpected result is that activation of endogenous Rac by Mε-containing Tiam1 proteins is sufficient for induction of membrane ruffling but not for stimulation of JNK. Alternatively, the lack of induction of JNK activity is caused by the different ultrastructural localization of the Mε-CS80 Tiam1 protein (compare Figs. 5 and 7) or may reflect the need for an intact NH2-terminal PH domain. Interestingly, similar results were obtained with membrane-targeted p110 phosphoinositide-3-kinase which was able to stimulate membrane ruffling but not gene transcription from the Jun-inducible Fos promoter (Reif et al., 1996). Whatever the mechanism, these results indicate that the localization of Tiam1 at the plasma membrane is also required for Rac-mediated stimulation of JNK activity.

**Discussion**

The data presented here demonstrate that Tiam1 is a cytoplasmic protein that is capable of associating with the plasma membrane. The NH2-terminal PH domain is essential for membrane association of Tiam1, and this membrane association is required for Rac-mediated induction of membrane ruffling and stimulation of JNK activity.
A short COOH-terminal fragment of Tiam1, C682 Tiam1, which lacks the NH2-terminal PH domain, did not associate with the plasma membrane in NIH3T3 cells or COS-7 cells and was unable to induce membrane ruffling (see Figs. 1 and 2). Similar to C1199 Tiam1 and (V12)Rac1, the C682 Tiam1 protein induces a tumorigenic phenotype in NIH3T3 cells (Van Leeuwen et al., 1995). This indicates that the Tiam1-induced formation of membrane ruffles and induction of a tumorigenic phenotype are triggered by two distinct signaling pathways. Since JNK activity could not be stimulated by C682 Tiam1 and none of the truncated or mutant Tiam1 proteins activated MAPK, it is unlikely that the induction of a tumorigenic phenotype is due to activation of JNK or MAPK. An explanation could be that tumorigenicity is caused by activation of cytoplasmic Rac, although we cannot exclude that cytoplasmic Tiam1 activates another, yet unknown GTPase. Both the C1199 and C682 Tiam1 proteins were also able to induce an invasive phenotype in T-lymphoma cells (Habets et al., 1994). As the localization of Tiam1 might be differently regulated in lymphoid cells compared to adherent COS and fibroblast cells, we are currently testing whether or not JNK is involved in the Tiam1/Rac-mediated induction of an invasive phenotype in T-lymphoma cells.

A detailed structural analysis showed that a small deletion in the NH2-terminal PH domain, but not the DH-adjacent COOH-terminal PH domain, abolished the membrane localization of Tiam1 and the subsequent induction of membrane ruffling. In all DH domain–containing GDS proteins analyzed thus far, the DH domain is flanked by a PH domain (Cerione and Zheng, 1996; Collard, 1996), suggesting that the DH–PH combination is a functional unit. Indeed, deletions in either the DH domain or the flanking PH domain of the protooncogenes Dbl, Ost, Dbs, and Lfc result in loss of transforming capacity (Ron et al., 1991; Horii et al., 1994; Whitehead et al., 1995a,b; Zheng et al., 1996). The transforming capacity of a mutant of Lfc, which carried a deletion in the PH domain, could be restored by the addition of a COOH-terminal Ras CAAX motif, suggesting that the localization of Lfc at the plasma membrane is required for its transforming capacity (Whitehead et al., 1995b). In contrast, the Ras-CAAX motif was not sufficient to replace the PH domain of Dbl, which is required for the presence of Dbl in the particulate fraction of cells (Zheng et al., 1996). Corresponding results were obtained for the NH2-terminal PH domain of Ras-guanine nucleotide release factor (GRF), suggesting that the association of Ras-GRF and Dbl in the particulate fraction is a prerequisite for their activity (Buchsbaum et al., 1996; Zheng et al., 1996). Together with pleckstrin and Ras-GRF, Tiam1 is one of a few proteins that contains two PH domains (Habets et al., 1994). Similarly to Ras-GRF, only the NH2-terminal PH domain of Tiam1 is involved in the localization of the protein. The COOH-terminal PH domain of Tiam1 has only moderate homology with other PH domains and lacks a highly conserved tryptophan residue in the COOH-terminal α-helix (Habets et al., 1994). Although a complete deletion of the DH-adjacent PH domain of Tiam1 abolished membrane ruffling, it did not interfere with the membrane localization of the protein (data not shown). What other functions can be attributed to this PH domain remains to be elucidated.

Figure 9. Stimulation of JNK activity by Tiam1. (A) COS-7 cells were transfected with pCMV-Flag-JNK1 and empty vector (pcDNA-neo), full-length Tiam1 (FL1591), or constitutively activated (V12)Rac1. Cotransfection with dominant-negative (N17)Rac1 was performed as indicated. The activity of immunoprecipitated Flag-JNK was determined 48 h after transfection by an in vitro kinase assay using bacterially expressed GST-Jun as a substrate. The expression of Tiam1, Myc-tagged (N17)Rac, and Flag-tagged JNK was analyzed by Western blotting and is shown underneath the graph. (B) NIH3T3 cells were transfected with pCMV-Flag-JNK1 and mutant Tiam1 constructs. JNK activity was determined as described. All data are presented as fold stimulation of empty vector controls. Equal amounts of expressed Flag-JNK1 and Tiam1 proteins, as determined by Western blotting, were used. Data represent mean ± standard deviation of at least two independent experiments.
Membrane-associated Tiam1 Mediates Rac Signaling

Several reports have demonstrated that isolated PH domains can bind in vitro to Gβγ subunits and phospholipids like phosphatidylinositol (4,5)bisphosphate (PIP2) and inositol (3,4,5)trisphosphate (IP3) (Harlan et al., 1994; Ferguson et al., 1995; Mahadevan et al., 1995; Touhara et al., 1995). Phosphoinositide-3-kinase, which stimulates the synthesis of phosphatidylinositol (3,4,5)trisphosphate (PIP3) from PIP2 (Hiles et al., 1992), has been implicated in the activation of Rac by PDGF and insulin (Wennstrom et al., 1994; Hawkins et al., 1995) and might be required for the induction of membrane ruffles and activation of JNK. Alternative explanations would be that the activity of Tiam1 is enhanced at the plasma membrane, or that Tiam1 is also involved in the translocation of Rac from the cytoplasm to the plasma membrane. In all these models, the controlled membrane association of Tiam1 is the only determinant for the induction of membrane ruffling by Rac. Since Mγ-C580 Tiam1, but not C580 Tiam1, induces membrane ruffling, it is unlikely that the activation of cytoplasmic Rac by Tiam1 leads to the membrane translocation of GTP-bound Rac. As discussed before, however, cytoplasmic GTP-bound Rac might be responsible for the induction of a tumorigenic phenotype by C682 Tiam1. Further exploration of these models will require the generation of antibodies that efficiently detect endogenous Tiam1 and Rac and tools to discriminate between active and inactive endogenous Rac.

Given the importance of PH domains in Tiam1 and other GDS proteins, it is conceivable that phospholipids and/or Gβγ subunits are involved in their intracellular localization and/or activation. The next challenge will be to identify the upstream signaling pathways and molecules that translocate and activate these GDS proteins.

We thank Drs. M. Karin, A. Eva, and T. van Biezen for their gift of constructs; G. Habets and F. van Leeuwen for their help in the initial studies; L. Oomen for his assistance with the confocal microscope; L. Oomen and N. Ong for preparation of some of the figures; and F. van Leeuwen, E. Roos, and R. Engers for critically reading the manuscript.

This work was supported by grants from the Netherlands Organization for Scientific Research and the Dutch Cancer Society to J.G. Collard.

Received for publication 8 October 1996 and in revised form 23 January 1997.
