Ectopic acromegaly due to a GH-secreting pituitary adenoma in the sphenoid sinus: a case report and review of the literature

Claudia Ramírez1, Laura-Cristina Hernández-Ramírez3, Ana-Laura Espinosa-de-los-Monteros1, Juan Manuel Franco1, Gerardo Guinto2 and Moises Mercado1*

Abstract

Background: In more than 98% of cases, acromegaly is due to a GH-secreting pituitary adenoma. The term “ectopic acromegaly” includes neuroendocrine tumors secreting GH releasing hormone (GHRH), usually located in the lungs, thymus and endocrine pancreas. Considerably less frequent are cases of ectopic acromegaly due to GH-secreting tumors located out of the pituitary fossa; except for one isolated case of a well-documented GH-secreting lymphoma, the majority of these lesions are located in the sphenoid sinus.

Case presentation: We present the case of a 45 year old woman with acromegaly whose MRI showed an empty sella without evidence of a pituitary adenoma but revealed a large mass within the sphenoid sinus. She underwent transsphenoidal surgery and the excised sphenoid sinus mass, proved to be a GH-secreting adenoma; the sellar floor was intact and no other lesions were found in the pituitary fossa. She required postoperative treatment with somatostatin analogs and cabergoline for clinical and biochemical control.

Conclusions: This case highlights the importance of carefully evaluating the structures surrounding the sellar area when a pituitary adenoma is not found with currently available imaging techniques. The finding of an intact sellar floor and duramater lead us to conclude that the patient’s tumor originated de novo from embryological pituitary remnants. Upon a careful review of the literature and a critical evaluation of our case we found neither clinical nor biochemical features that would distinguish an ectopic from the more common eutopically located somatotrophinoma.

Keywords: Ectopic acromegaly, Sphenoid sinus, GH-secreting adenoma

Background
Acromegaly results from an excessive GH secretion by a pituitary adenoma in over 98% of the cases [1]. It is a relatively rare condition, with a prevalence of 20–40 cases per million and an incidence of 3–4 new patients per year [1]. In less than 2% of the cases, acromegaly results from GHRH-secreting neuroendocrine tumors usually located in the lungs, thymus and endocrine pancreas [1,2]. Even less frequent are cases of real ectopic GH secretion by adenomas arising in pituitary remnants in this sphenoid sinus or by other neoplastic lesions like lymphomas [3,4].

Ectopic acromegaly due to a GHRH neuroendocrine tumor (NET) should be suspected when a patient presents with all the clinical and biochemical features of the disease but without evidence of a pituitary adenoma on MRI [2,5,6]. In this scenario, the pituitary gland may appear hyperplastic or even normal and the condition is documented by the demonstration of an elevated serum GHRH level. What follows is the localization of the NET by means of high resolution CT and 111In-labeled octreotide scintigraphy [2,5,6]. The absence of a pituitary adenoma in a patient with clinical and biochemical evidence of GH excess, should prompt a careful evaluation of the sphenoid sinus, since pituitary remnants, abnormally...
located at this site could be the source of the problem [3]. In these rare cases MRI of the region can be entirely normal or may show an empty sella [7].

We here in report the case of a woman with acromegaly without a pituitary lesion in whom GH-secreting adenomatous tissue in the sphenoid sinus proved to be the source of her hypersomatotrophism.

**Case presentation**

A 45-year-old woman presented with a 5-year history of menstrual abnormalities, knee and elbow arthralgias, hands and feet enlargement, coarsening of facial features, fatigue, dental spacing and symptoms of obstructive sleep apnea (snoring and day-time sleepiness). On physical exam her blood pressure was 180/100 mmHg, pulse 80 and regular, weight 65 Kg, height 1.55 m. She had evident acral enlargement with prominence of supracilliary arches and nose bridge, prognathism and dental spacing. Numerous pigmented skin tags were visible in her anterior chest wall and there was slight acanthosis nigricans in her neck and axillary regions. Her thyroid was palpable and somewhat nodular but without distinct lesions. The diagnosis of acromegaly was confirmed by an age adjusted IGF-1 level 4.8 times the upper limit of normal (ULN) and a basal and post glucose GH concentrations of 7.7 ng/mL and 2.5 ng/mL, respectively (Table 1). The rest of anterior pituitary hormones were normal (Table 1).

MRI revealed an empty sella without clearly defined intrapituitary lesions. The sphenoid sinus was occupied by a heterogeneous but mostly hyperintense mass (Figure 1). CT scan did not reveal any abnormalities of the sellar floor. $^{111}$In-labeled octreotide scintigraphy showed abnormal uptake in the sellar remnant on postoperative MRI (Figure 2).

Upon treatment with octreotide-LAR 20 mg monthly for 4 months, the patient reported clinical improvement of her headaches and joint pain, and her GH and IGF-1 levels decreased to 2.4 ng/mL and 3.5 times the ULN, respectively. She underwent surgical resection of the sphenoid sinus mass via an endonasal, transsphenoidal approach; the surgeon found an intact sellar floor and duramater. Both structures were opened looking for a possible intrasellar tumor, but only a protrusion of the arachnoid membrane into the sella was found. Pathological examination of the resected mass revealed an acidophilic adenoma on HE and immunohistochemistry was positive for GH (Figure 3).

Six months postoperatively she still had biochemically active acromegaly despite the absence of a tumor remnant on postoperative MRI (Figure 1). She was treated with a combination of octreotide LAR and cabergoline, eventually achieving an adequate hormonal control (Figure 4).

**Discussion and review of the literature**

Pituitary tissue remnants can settle along the embryological migration and invagination pathway of Rathke’s pouch [8]. Such remnants have been found in the mucoperiosteum of the vomerosphenoidal articulation, the sphenoid bone, or more commonly, within the sphenoid sinus [9-11]. Since these embryological remnants lie out of the hypophysial-portal system they are unlikely to be regulated by hypothalamic releasing hormones [12]. However, some data, albeit controversial, suggest they can respond to feedback inhibition [12]. Alternatively, the finding of adenomatous pituitary tissue within the sphenoid sinus can be explained by a pituitary tumor that protrudes inferiorly due to the pressure exerted by a large empty sella. This scenario is likely to have occurred when the sellar floor is eroded or frankly absent with the duramater extending downwards into the sphenoid sinus [3,8,10,13-16].

Ectopic acromegaly due to a GH-secreting adenoma arising from abnormally located pituitary tissue is an extremely rare entity; barely cases have been reported in the literature in the past 30 years (Table 2). The most frequent localization for these ectopic tumors has been the sphenoid sinus, followed by the clivus and isolated cases of tumors in the cavernous sinus or the suprasellar region [3,8,11,13-19]. Clinically, patients present the typical symptoms and signs of acromegaly. Sinus congestion symptoms are not commonly reported, which is interesting considering that some of the tumors fully occupy the sphenoid sinus. Biochemical documentation of acromegaly with varying combinations of basal and post-glucose GH as well as IGF-1 levels is provided in 10 of these 13 cases; PRL was measured in 7 and found to be elevated in three. No biochemical features can be found that would differentiate ectopic from eutopic acromegaly. Neither the degree of hypersomatotropinemia, nor the presence of hyperprolactinemia were associated with a

---

### Table 1 Preoperative hormone levels

| Hormone          | Result   | Normal range |
|------------------|----------|--------------|
| IGF-1 (ng/mL)    | 920      | 84-191       |
| IGF-1 x ULN      | 4.81     | < 1          |
| Basal GH (ng/mL) | 7.7      | -            |
| Nadir post-glucose GH (ng/mL) | 2.5 | < 0.4 |
| Prolactin (ng/mL) | 12.27  | 3.4-24.1     |
| LH (mU/mL)       | 10.4     | Postmenopausal range > 10 |
| FSH (mU/mL)      | 36.4     | Postmenopausal range > 20 |
| Estradiol (pg/mL)| 34.7     | 12-211       |
| Cortisol (µg/mL) | 17.5     | 5-25         |
| Free T4 (ng/dL)  | 1.4      | 0.93-1.70    |
| TSH (mU/L)       | 1.95     | 0.27-4.20    |
particular ectopic location or the concomitant finding of an empty sella. The careful evaluation of the sphenoid sinus in our patient by MRI revealed the presence of a mass, which avidly took up $^{111}$In-labeled octreotide. Thus, the possibility that such mass in the sphenoid sinus was in fact the source of the excessive GH was entertained preoperatively. To our knowledge, none of the reported cases of ectopic acromegaly due to ectopically located GH-secreting adenomas have been evaluated with octreotide scintigraphy. The GH-secreting nature of the ectopic tumor was documented by immunohistochemistry in 12 of the reported cases; in six, there was concomitant, PRL immunostaining (Table 2). There is not sufficient data to ascertain if these six tumors were real mammo-somatotrophe adenomas, although that was likely the case in the three patients who had significant

**Figure 1** Preoperative (left) and postoperative (right) MRI. A) T1W sagital, gadolinium-enhanced; B) T1W coronal, gadolinium-enhanced; C) T2W coronal.
hyperprolactinemia. Our patient’s tumor also showed faint PRL immunostaining and yet her serum PRL was normal.

Among the 9 cases with lesions located in the sphenoid sinus, 5 were reported to have bone gaps or erosions of the sellar floor, and duramater defects were found in one (Table 2). Information regarding surgical outcome is described in 10 of the 13 cases found in the literature, with half of them achieving normal IGF-1 levels. In our case both, the sellar floor and the duramater were intact and although the duramater was protruding inferiorly, this could had been the result of the associated arachnoidcele. Although GH and IGF-1 levels improved after surgery in our patient, she remained biochemically active, and required combination therapy with high dose octreotide LAR and cabergoline, as it is frequently the case with eutopically located tumors. We decided against surgical reintervention in view of the absence of a tumor remnant upon follow up MRI and the low probability of achieving biochemical remission [20].

Conclusions

In contrast to the few reported cases with this condition, our case was fully worked up preoperatively both biochemically as well as from an imaging standpoint (MRI and octreoscan scintigraphy); the excised adenomatous tissue was analyzed both by HE and immunohistochemistry for pituitary hormones, and proved to be a GH-secreting tumor. The surgical findings support the hypothesis that our patient’s adenoma originated from pituitary embryological remnants located in the sphenoid sinus. This is probably the first case of ectopic acromegaly due to a sphenoid sinus adenoma to be treated successfully with a combination of a somatostatin analog and a dopamine agonist.

Consent

Written informed consent was obtained from the patient for publication of this Case report and any accompanying images. A copy of the written consent is available for review by the Editor of this journal.

GH: Growth hormone; IGF-1: Insulin-like growth factor type 1; LH: Luteinizing hormone; FSH: Follicle stimulating hormone; PRL: Prolactin; TSH: Thyroid stimulating hormone; FT4: Free thyroxine; GRH: Growth hormone releasing hormone; MRI: Magnetic resonance imaging; CT: Computed tomography; ULN: Upper limit of normal; CBG: Cabergoline.

Competing interests
The authors have no conflict of interest to declare.

Authors’ contributions
CR and MM drafted the manuscript. CR, LH, JMF and ALE collected all medical reports of the patient. ALE and MM were the neuroendocrinologists in charge of the case and GG was the neurosurgeon who performed the transsphenoidal resection of the tumor, contributing the technical aspects of the procedure and its findings. MM coordinated the group. All authors read and approved the final manuscript.

Authors’ information
Claudia Ramírez, MD, MSc: Endocrinologist, Associate Professor of Medicine, Universidad Nacional Autónoma de México Faculty of Medicine. Staff investigator, Experimental Endocrinology Unit, Hospital de Especialidades CMN SXXI, IMSS, México City. Research interests: Pituitary adenomas, Neuroendocrine tumors.
Laura-Cristina Hernández-Ramírez, MD: Endocrinologist, currently completing her PhD in molecular endocrinology at the Centre for...
Endocrinology, William Harvey Research Institute, Barts and The University of London School of Medicine.

Ana Laura Espinosa de los Monteros, MD: Associate Professor of Medicine Universidad Nacional Autónoma de México Faculty of Medicine. Senior attending endocrinologist, Endocrinology Service, Hospital de Especialidades, CMN SXXI, IMSS, México City. Member of the National System of Investigators. Research interests: Pituitary adenomas, acromegaly and Cushing's disease.

Juan Manuel Franco: Sixth year medical student, Universidad Nacional Autónoma de México Faculty of Medicine. Currently completing a 12-month research fellowship at the Experimental Endocrinology Unit, Hospital de Especialidades, CMN SXXI, IMSS, México City.

Gerardo Guinto, MD: Professor of Neurosurgical Surgery Universidad Nacional Autónoma de México Faculty of Medicine, Head of the Neurosurgery Service, Hospital de Especialidades, CMN SXXI, IMSS, México City. Member of the National System of Investigators. Reviewer for Journal of Neurosurgery, Neurosurgery (editorial board member) and World Neurosurgery. Research interests: Skull base and pituitary surgery.

Moises Mercado, MD, FRCP(C): Professor of Medicine Universidad Nacional Autónoma de México Faculty of Medicine. Director Experimental Endocrinology Unit, Senior Consultant, Endocrinology Service, Hospital de Especialidades, CMN SXXI, IMSS, México City and ABC Medical Center Neurological Unit.
