Abstract

We revisit the long-standing problem of supersymmetric grand unified theory (GUT), the doublet-triplet splitting problem. We discuss whether symmetry which controls the $\mu$ term in the minimal supersymmetric standard model is compatible with GUT. We find that the symmetry must be broken at the GUT scale. A similar argument also shows that the $R$ symmetry, which is important for low energy supersymmetry, must be broken down to a $Z_{2R}$ symmetry at the GUT scale. We propose a new prescription to achieve the doublet-triplet splitting by symmetry. There, the symmetry which controls the $\mu$ term is spontaneously broken at the GUT scale by order parameters which are charged under other symmetries. Bilinear terms of triplet Higgses are charged under the other symmetries, while those of doublet Higgses are not. Then triplet Higgses directly couple to the order parameters and hence obtain GUT scale masses, while doublet Higgses obtain suppressed masses. The broken $R$ symmetry can be also effectively preserved by a similar prescription. As a demonstration, we construct an $SU(5) \times SU(5)$ GUT model. We also comment on unification of yukawa couplings.
1 Introduction

For decades, supersymmetry (SUSY) has been expected to be an important key for physics beyond the Standard Model (SM). In particular, the supersymmetric standard model (SSM) has been thought to be very successful since it allows a vast separation of low energy scales from high energy scales \[1-4\] such as the Planck scale or the scale of the Grand Unified Theory (GUT) \[5\]. The SSM has been also supported by unification of the gauge coupling constants of the SM at around \(10^{16}\) GeV. Interesting connection between the proton stability and the stability of a dark matter candidate, the lightest supersymmetric particle (LSP), also illuminates the success of the SSM.

With the Large Hadron Collider (LHC) showing no evidence for SUSY \[6\], however, the situation for natural electroweak symmetry breaking by SUSY particles around a sub TeV scale has grown increasingly severe. Besides, the observed Higgs boson mass of 125 GeV \[7\] seems to point the masses of SUSY particles in a tens to hundreds TeV range in the minimal SSM (MSSM). These facts might suggest that it is more difficult to obtain immediate hints on the SSM from collider experiments than anticipated before the LHC experiments.

With this little gloomy outlook, it is worthy to reappraise one of the strongest motivations of the SSM, the successful GUT, and try to obtain implications on the structure of the SSM. In particular, it is important to think again a strong correlation between the \(\mu\)-problem in the MSSM and the doublet-triplet splitting problem in the SUSY GUT \[3,8,9\]. On the one hand, a variety of solutions to the doublet-triplet splitting problem have been proposed so far, such as missing partner mechanism \[10,11\], missing vacuum expectation value (VEV) mechanism \[12\], product GUT models \[13\], and orbifold GUT models \[14,15\]. On the other hand, many successful models of the MSSM have been proposed in which the size of the \(\mu\)-term is controlled by a symmetry such as the \(R\) symmetry \[17,18\] or the Peccei-Quinn symmetry \[19,1\]. Although these two problems are intimately related with each other, the solutions to these problems are often discussed separately.

In this paper, we discuss these issues with a special emphasis on the consistency be-

---

1The symmetry which forbids the \(\mu\)-term is also important to suppress the so-called the dimension five proton decay operators.
tween a symmetry which controls the $\mu$-term and solutions to the doublet-triplet splitting problem. In fact, it has been shown in Refs. [20,21] that the low energy symmetry which forbids the $\mu$-term at the GUT scale cannot be consistently embedded in GUT models when the SM gauge groups are embedded into a simple GUT group (see also Ref. [22]). As we will see, this no-go theorem can be extended to GUT models based on a product group such as $SU(5) \times SU(5)$ where the SM gauge groups are embedded into the GUT group so that the coupling unification is automatically maintained.\footnote{If the SM gauge groups are embedded into an asymmetric product gauge groups such as $SU(5) \times U(3)$, it is actually possible to embed the low energy symmetry which forbids the $\mu$-term consistently to the GUT [13,16]. In such models, however, the coupling unification is not automatically achieved and requires that the gauge couplings other than that of $SU(5)$ are strong at the GUT scale.} It should be noted that this extension is non-trivial since the low energy symmetry does not necessarily commute with the GUT group in the case of a product GUT.

After discussing the no-go theorem, we discuss how to mend the low energy symmetry in the MSSM which forbids the $\mu$-term with GUT models with automatic coupling unification. There, we show a prescription such that the symmetry which forbids the mass of the doublet (hereafter, we refer to this symmetry as “doublet symmetry”) is broken at the GUT scale while its breaking does not generate the $\mu$-term of the GUT scale. Concretely, we assume that the order parameters of the doublet symmetry are also charged under other symmetries under which the doublets are not charged. Then, if the color triplet Higgses are charged under the above other symmetries, the triplet can obtain the mass of the GUT scale (hereafter, we refer to the other symmetries as the “triplet symmetries”) while the doublet Higgs mass is suppressed due to the lack of the charges of the triplet symmetries. It should be emphasized that this mechanism is close but opposite to the “collective symmetry breaking”, where Lagrangian terms charged under multiple symmetries are more suppressed. In our mechanism, instead, less charged fields obtain more suppressed masses, i.e., the haves get large masses while the have-nots get no masses at the GUT scale.

We also find that the $R$ symmetry, which is important for low energy SUSY, should be broken down to $Z_{2R}$ symmetry at the GUT scale when the coupling unification is guaranteed. In general, such a large breaking leads to a large VEV of the superpotential, which is incompatible with low energy SUSY. This worry can be easily solved if the order
parameters of the $R$ symmetry are also charged under other symmetries, as in the case of the doublet symmetries.

By observing the similar requirements on the doublet symmetry and the $R$ symmetry, we demonstrate GUT model building where the doublet symmetry is the $R$ symmetry. As order parameters of the $R$ symmetry are charged under triplet symmetries, the $\mu$-term is not generated at the GUT scale. The breaking of the $R$ symmetry generates a constant term in the superpotential which is suppressed by triplet symmetries. Eventually, the VEV of the superpotential leads to the $\mu$-term of the order of the gravitino mass, $m_{3/2}$, via Planck-suppressed operators [17,18]. As a bonus of our concrete example, we find an interesting connection between the gravitino mass and the GUT scale. We also show that the infamous problem of the unification of down-quark yukawa couplings and charged-lepton yukawa couplings can be solved rather simply in our example.

This paper is organized as follows. In Sec. 2, we prove the above mentioned no-go theorem on a symmetry which forbids the $\mu$-term. We also propose a prescription to achieve the doublet-splitting by using triplet symmetries. In Sec. 3, we discuss the consistency between the $R$ symmetry and unification. In Sec. 4, we construct a concrete realization of the mechanism. In Sec. 5, we discuss the detailed vacuum structure and the mass spectrum of the model constructed in Sec. 4. The final section is devoted to conclusions and discussion.

2 Mass Splitting and Unification

2.1 Doublet symmetry and coupling unification

In this subsection, we discuss the consistency between a low energy symmetry which forbids the $\mu$-term in the MSSM and the GUT gauge symmetry. Let us refer to the low energy symmetry which is embedded in the GUT as the doublet symmetry. Then, if the doublet symmetry remains unbroken at the GUT scale, the doublet mass is generated only after the remaining doublet symmetry is broken at a scale well below the GUT scale. If the triplet Higgs mass is, on the other hand, allowed by the doublet symmetry in some way, they obtain the mass of the GUT scale. This is the situation assumed in successful models of the MSSM where the $\mu$-problem is solved by symmetries. Unfortunately, however, we
will immediately see that this possibility is incompatible with GUT models where the
coupling unification is automatically maintained.

Since we are interested in GUT models which exhibit automatic coupling unification,
let us first discuss a $SU(5)$ GUT model as an example. The following arguments can
be extended to models with more generic simple GUT gauge groups. Throughout this
paper, we assume that the doublet Higgses are placed in chiral supermultiplets $H$ and $\bar{H}$
transforming $5 \oplus \bar{5}$. This choice is quite natural since it allows the yukawa interactions
in the MSSM easily embedded in the GUT model where quarks and leptons are unified
into chiral supermultiplets transforming $5 \oplus 10$.

Now, let us show that the doublet-triplet splitting with the unbroken doublet symme-
try is impossible under the reasonable assumption: the Higgs multiplets are not mixed
with quark and lepton multiplets in the GUT representations. As we have mentioned
earlier, we have discarded the possible mixing since such a complicated structure makes it
difficult to obtain appropriate yukawa interactions while keeping the proton stability etc.
Under this assumption, we can discuss the anomaly matching condition of the doublet
symmetry only within the Higgs sector.

We normalized the sum of the charges of a pair of doublet Higgses as $2q$\footnote{When the
doublet symmetry is the $R$ symmetry, charges we discuss denote those of fermion com-
nents.}. Below the GUT scale, only the doublet Higgses contribute to the anomaly of the
doublet symmetry, $D$. Thus, the contributions of the Higgs sector to $D-SU(3)_c-SU(3)_c$ and
$D-SU(2)_L-SU(2)_L$ are given by

$$A_{D-SU(3)_c-SU(3)_c}^{Higgs} = 0, \quad A_{D-SU(2)_L-SU(2)_L}^{Higgs} = 2q,$$

and hence, they are not equal with each other. If the doublet symmetry is unbroken, on
the other hand, the anomaly matching condition leads to

$$A_{D-SU(3)_c-SU(3)_c}^{Higgs} = A_{D-SU(2)_L-SU(2)_L}^{Higgs} = A_{D-SU(5)-SU(5)}^{Higgs},$$

which is not consistent with Eq. (1). Therefore, we find that the unbroken doublet sym-
metry is incompatible with the doublet-triplet splitting in the $SU(5)$ GUT model. This
arguments can be easily extended to GUT models based on simple GUT groups such as
$SO(10)$ or larger groups which contain a unique $SU(5)$ subgroup to which the SM gauge groups are embedded in. In such cases, the above arguments can be repeated by using the $SU(5)$ subgroup.

Next, let us consider models with product GUT gauge groups. Even in such cases, the coupling unification is also automatically maintained when the SM gauge groups originate from a single simple group. For example, in $SU(5)_1 \times SU(5)_2$ models, $SU(3)_c$, $SU(2)_L$ and $U(1)_Y$ originate from a vector $SU(5)$ part of $SU(5)_1 \times SU(5)_2$, which leads to automatic coupling unification. Unfortunately, however, things are no different in this class of product GUT models as for the no-go theorem. That is, as we have shown, $A_{D,SU(3)_c,SU(3)_c}^{\text{Higgs}} \neq A_{D,SU(2)_L,SU(2)_L}^{\text{Higgs}}$ if the doublet-triplet splitting occurs successfully. Then, the anomaly matching condition of the doublet symmetry and the GUT gauge group (in particular the vector $SU(5)$ part) again contradicts with $A_{D,SU(3)_c,SU(3)_c}^{\text{Higgs}} \neq A_{D,SU(2)_L,SU(2)_L}^{\text{Higgs}}$. It should be noted the anomaly matching should be satisfied even when the low energy doublet symmetry is a diagonal unbroken part of a symmetry and a subgroup of $SU(5)_1 \times SU(5)_2$ which do not commute with the SM gauge groups. This is because the subgroup of $SU(5)_1 \times SU(5)_2$ is anomaly-free. Therefore, we again find that the unbroken doublet symmetry is incompatible with the doublet-triplet splitting in a class of product GUT models where the SM gauge groups are embedded in a single simple group.

Before closing our discussion, let us comment on possible ways to evade the no-go theorem.

- **Higgs-matter mixing:** If Higgs multiplets mix with quarks and leptons multiplets, the above anomaly argument must involve quarks and leptons, and hence, we might be able to evade the no-go-theorem. It would not be easy to obtain appropriate Yukawa couplings of quarks and leptons. Also, it is non-trivial whether the $R$-parity can be conserved.

---

4 The discussion in [20, 21] cannot be used when the low energy doublet symmetry contains a subgroup of $SU(5)_1 \times SU(5)_2$, since their arguments are based on the Weyl symmetry of the characters of representations for a fixed charges of the doublet symmetry.

5 In product GUT models such as $SU(5) \times U(3)_H$, the difference of the anomalies does not lead to any inconsistency, since $SU(3)_c$ is a linear combination of $SU(3) \supset SU(5)$ and $SU(3)_H$ while $SU(2)_L \supset SU(5)$. Even in this case, if the product group is embedded in a simple group eventually, the above no-go theorem holds.

6 For simple GUT gauge groups, the discussion in Refs. [20, 21] excludes the first possibility.
• **Accidentally light additional field:** If there are GUT incomplete light multiplets (we refer them surplus multiplets) with non-trivial charges under the doublet symmetry, the anomaly mismatching can be evaded. However, those multiplets ruin the coupling unification, generically. If there are additional GUT incomplete multiplets, whose masses are allowed by the doublet symmetry but accidentally as large as the masses of the surplus multiplets, and they fit into GUT complete multiplets, the coupling unification is maintained. However, the lightness of the additional GUT incomplete multiplets brings up the mass splitting problem again.

• **Explicite Breaking of the doublet symmetry by strong dynamics:** If the doublet symmetry is explicitly broken, the above anomaly argument is invalidated. In $SU(5) \times SU(5)$ models presented in Ref. [23,24], the classical doublet symmetry has anomaly of a hidden strong gauge interaction. A dynamically generated superpotential explicitly breaks the classical doublet symmetry. The doublet mass is, however, absent due to missing VEVs. The doublet mass is given by the breaking of the classical doublet symmetry at a low energy scale.

2.2 Broken doublet symmetry and use of triplet symmetry

In this paper, we take a different approach. We break the doublet symmetry *at the GUT scale*. Then the above mentioned no-go theorem, which is based on the low energy theory with unbroken doublet symmetry, does not hold anymore.

The doublet symmetry broken at the GUT scale, however, seems to lead to a doublet mass around the GUT scale. To avoid the generation of the doublet mass at around the GUT scale, we assume that the order parameters of the doublet symmetry are charged under some other symmetries. We refer to those additional symmetries as “triplet symmetries”. The triplet Higgses (and other unwanted fields) are charged under the triplet symmetries appropriately. Then the order parameters of the doublet symmetry may directly couple to the triplet Higgses and give GUT scale masses to them. On the other hand, if the doublet Higgses are neutral under the triplet symmetries, direct couplings between the order parameters and the doublet Higgses are forbidden. The triplet symmetries may control flavor structure of quarks and leptons, if the doublet Higgses are charged under them, while keeping the doublet-triplet splitting.
is given only by higher dimensional operators and hence is suppressed in comparison with the GUT scale: the doublet symmetry is effectively preserved as a good approximate symmetry below the GUT scale, with an aid of the triplet symmetries.\footnote{The doublet-triplet splitting with broken doublet symmetry has been also considered in Ref.\cite{26}.}

This prescription should be compared with the usual collective symmetry breaking mechanism in which Lagrangian terms charged under multiple symmetries are more suppressed than the less charged ones. In our prescription, instead, the masses of less charged fields are more suppressed. That is, the \textit{have}s get large masses while the \textit{have-not}s get no masses at the GUT scale. From the viewpoint of the low energy MSSM models, this mechanism is advantageous, since the \(\mu\)-term looks controlled only by the doublet symmetry, and hence, many successful ideas to control the \(\mu\)-term by a symmetry can be embedded in GUT models without changing the symmetry structure of the low energy MSSM.

3 \(R\) symmetry and Unification

In low energy SUSY, the VEV of the superpotential, \(W_0\), is required to be small in order to achieve an almost vanishing cosmological constant. Such a small VEV can be achieved if there is a symmetry which prevents \(W_0\) from being very large, namely an \(R\) symmetry. In this section, let us comment on the consistency between the \(R\) symmetry and unification. We immediately see that the \(R\) symmetry should be broken at the GUT scale in GUT models with automatic coupling unification.

Now, let us repeat the above arguments of the anomaly matching in the case of the \(R\) symmetry. In the MSSM gaugino sector, the anomalies of the \(R\) symmetry are given by,

\[
A_{\text{Gaugino}}^{R-SU(3)_c-SU(3)_c} = 6, \quad A_{\text{Gaugino}}^{R-SU(2)_L-SU(2)_L} = 4. \quad (3)
\]

If the \(R\) symmetry is unbroken, on the other hand, the anomaly matching condition leads to

\[
A_{\text{Gaugino}}^{R-SU(3)_c-SU(3)_c} = A_{\text{Gaugino}}^{R-SU(2)_L-SU(2)_L} = A_{\text{Gaugino+GUT-breaking}}^{R-SU(5)-SU(5)}. \quad (4)
\]

Here, \(SU(5)\) denotes a simple subgroup of the GUT gauge group in which the standard model gauge groups are embedded in. It should be noted that the GUT breaking sec-
tor contributes to the matching condition since the mass partners of heavy GUT gauge multiplets are the would-be Nambu-Goldstone modes. It should be also noted that the multiplets in the GUT breaking sector never mix the quark, the lepton nor the Higgs sectors. Thus, the quark, the lepton nor the Higgs sectors do not contribute to the above condition. We find that the anomalies in Eq. (3) are consistent with the condition in Eq. (4) only when the $R$ symmetry is broken down to $Z_{2R}$ at the GUT scale.

This no-go theorem shows that it is not easy to embed a low energy theory with an $R$ symmetry into GUT models. As in the case of the doublet symmetry, one way to make the low energy $R$ symmetry compatible with GUT models is to assume that the order parameters of the $R$ symmetry are charged under other symmetries. In this case, if the low energy fields are neutral under the other symmetries, the $R$ symmetry is effectively preserved as a good approximate symmetry below the GUT scale.

The other symmetries are also helpful to suppress the VEV of the superpotential, so that the gravitino mass is small enough to be compatible with low energy SUSY. In the concrete model in the following section, we obtain the gravitino mass as small as $O(10^2 - 10^6)$ GeV (see Fig. 1), which is consistent with gravity mediation. It seems to be, however, not easy to obtain a gravitino mass appropriate for low energy gauge mediation.

4 $R$ symmetry as doublet symmetry

As we have discussed above, the doublet symmetry as well as the $R$ symmetry are required to be broken at the GUT scale. If the order parameters of these symmetries are charged under other symmetries, they are effectively preserved below the GUT scale. By observing this similarity, it is quite enticing to identify the $R$ symmetry as a doublet symmetry.

In fact, the use of $R$ symmetry to control the $\mu$-term in the MSSM is considered to be one of the most successful solution to the $\mu$-problem [17, 18]. When the pair of doublet Higgses has a vanishing $R$-charge (i.e. charge $-2$ in terms of the charge of fermionic components), the $\mu$-term of the gravitino mass size is naturally generated when the doublet Higgses couples to the VEV of the superpotential. It should be emphasized that this solution works without having singlet SUSY breaking fields unlike the usual Giudice-Masiero mechanism [27]. This mechanism is, therefore, particularly suitable for a class of
Table 1: Charge assignment of chiral multiplets. The charges of $\phi$ and $v^n$ are uniquely determined by the definitions of the symmetries, $Z_{2nR}$ and $Z_{n+1}$. The vanishing charges of $H_1$ and $\bar{H}_1$ are the simplest implementations of the $Z_{2nR}$ as the doublet symmetry and $Z_{n+1}$ as the triplet symmetry. The charge assignments of $\Phi_2$ and $\bar{\Phi}_2$ are generic at this point. Since we eventually allow the Higgs bi-linear terms in Eq. (13), the charges of $H_2$ and $\bar{H}_2$ and $\Phi_3$ are subsequently determined for given charges of $\Phi_3$ and a given value of $m = 1, 2$.

|          | $\phi$ | $v^n$ | $\Phi_3$ | $\bar{\Phi}_2$ | $\Phi_2$ | $H_1$ | $H_1$ | $H_2$ | $H_2$ |
|----------|--------|-------|----------|----------------|----------|-------|-------|-------|-------|
| $Z_{2nR}$ | 2      | 0     | $r_3$    | $r_2$         | $2 + 2m - r_3$ | $r_2$  | 0     | 0     | $2 - r_3$ | $r_3 - 2m$ |
| $Z_{n+1}$ | -1     | 1     | $q_3$    | $q_2$         | $-m - q_3$ | $q_2$  | 0     | 0     | $-q_3$ | $q_3 + m$ |
| $SU(5)_1$ | 1      | 1     | 5        | 5             | 5         | 5     | 5     | 5     | 5     |
| $SU(5)_2$ | 1      | 1     | 5        | 5             | 5         | 5     | 1     | 1     | 5     |

4.1 $R$ symmetry breaking and gravitino mass

We consider a discrete $R$ symmetry, $Z_{2nR}(n > 1)$, as the doublet symmetry. We assume that the discrete $R$ symmetry $Z_{2nR}$ is spontaneously broken by the following superpotential,

$$W = v^n \phi - \frac{\lambda}{n + 1} \phi^{n+1},$$

where $v^n$ and $\lambda$ are constants and $\phi$ is a chiral multiplet. Here and hereafter, we take the reduced Planck mass to be unity.

The charge assignments of $\phi$ and $v^n$ are as given in Table 1. There, we introduce a discrete symmetry $Z_{n+1}$ along with $Z_{2nR}$ symmetry, which will be identified with a part of triplet symmetries in the later discussion. The constant, $v^n$, is a spurious field of the breaking of $Z_{n+1}$ which may be considered to be generated dynamically.

At the vacuum, the $R$ symmetry is spontaneously broken down to $Z_{2R}$ symmetry. The high scale SUSY breaking models \[28–31\] with a gravitino mass in hundreds to thousands TeV range. Gaugino masses are dominantly given by the anomaly mediation \[32\] (see also \[33–35\]), where no singlet SUSY breaking fields are required\[9\].

\[9\]The absence of singlet SUSY breaking fields is advantageous by itself in view of the so-called Polonyi problem \[36–38\].
Figure 1: The VEV of $\phi$ for a given gravitino mass $m_{3/2}$ for a given order of the discrete $R$ symmetry, $Z_{2n R}$. Here, we have taken $\lambda = 1$.

VEV of $\phi$ and that of the superpotential are given by

$$\langle \phi \rangle = \lambda^{-1/n} v, \quad W_0 \equiv \langle W \rangle = \frac{n}{n+1} \lambda^{-1/n} v^{n+1} = \frac{n}{n+1} \lambda \langle \phi \rangle^{n+1}. \quad (6)$$

In Fig. 1 we show the relation between the gravitino mass $m_{3/2} = W_0$ and $\langle \phi \rangle$ for $n = 3$-7. Here, we take $\lambda = 1$. It should be noted that $\langle \phi \rangle$ is around the GUT scale $\sim 10^{16}$ GeV for a wide range of $m_{3/2}$ with $n = 5$-7. Since the $R$ symmetry is broken down to $Z_{2R}$, the $R$ symmetry itself does not forbid the doublet Higgs mass of the GUT scale anymore. As we demonstrate below, the triplet symmetries instead forbid the doublet Higgs mass although the doublet Higgses are neutral under the triplet symmetries. Eventually, the MSSM have a discrete $R$ symmetry as a good approximate symmetry.

4.2 $SU(5)_1 \times SU(5)_2$ breaking

To implement the triplet symmetries, let us consider an $SU(5)_1 \times SU(5)_2$ GUT gauge group [39] as an example, where, as we will see shortly, the doublet-triplet splitting is achieved rather easily [10]. To break $SU(5)_1 \times SU(5)_2$ down to $SU(3)_c \times SU(2)_L \times U(1)_Y$, we introduce four chiral multiplets in the bi-fundamental representation, $\Phi_3$, $\Phi_2$, $\bar{\Phi}_3$ and $\bar{\Phi}_2$ (see Table 1) which transform under $SU(5)_1 \times SU(5)_2$ as,

$$\Phi \rightarrow e^{i\alpha_1 T_I} \Phi e^{-i\alpha_2 T^I}, \quad \bar{\Phi} \rightarrow e^{i\alpha_1 T_I} \bar{\Phi} e^{-i\alpha_2 T^I}. \quad (7)$$

[10]The use of the product is not mandatory to implement the prescription in Sec 2.2.
Here, $T^I (I = 1-24)$ are generators of $SU(5)$ and $\alpha_I^1$ and $\alpha_I^2$ are parameters of $SU(5)_1$ and $SU(5)_2$ transformations, respectively. Specifically,

$$T^{1-8} = \begin{pmatrix} \lambda^{a=1-8} & 0 \\ 0 & 0 \end{pmatrix}, \quad T^{9-11} = \begin{pmatrix} 0 & 0 \\ \frac{1}{2} \sigma^{i=1-3} & 0 \end{pmatrix}, \quad T^{24} = \frac{\sqrt{15}}{30} \begin{pmatrix} 2 \times 1_3 & 0 \\ 0 & -3 \times 1_2 \end{pmatrix}, \quad (8)$$

where $\lambda^a$ are Gell-Mann matrices and $\sigma^i$ are Pauli matrices. We assume that the vacuum with $SU(3)_c \times SU(2)_L \times U(1)_Y$ symmetry is achieved by the following VEVs,

$$\langle \Phi_3 \rangle = v_3 \begin{pmatrix} 1_3 \\ 0 \\ 0 \end{pmatrix}, \quad \langle \bar{\Phi}_3 \rangle = \bar{v}_3 \begin{pmatrix} 1_3 \\ 0 \\ 0 \end{pmatrix}, \quad \langle \Phi_2 \rangle = v_2 \begin{pmatrix} 0 & 0 \\ 0 & 1_2 \end{pmatrix}, \quad \langle \bar{\Phi}_2 \rangle = \bar{v}_2 \begin{pmatrix} 0 & 0 \\ 0 & 1_2 \end{pmatrix}, \quad (9)$$

where $1_\ell$ denotes the $\ell$-dimensional unit matrix. The remaining $SU(3)_c$, $SU(2)_L$ and $U(1)_Y$ transformations are given by parameters $\alpha_{1-8}^1 = \alpha_{1-8}^2$, $\alpha_{9-11}^1 = \alpha_{9-11}^2$ and $\alpha_{24}^1 = \alpha_{24}^2$, respectively. As long as $v_3 \sim v_2$, the coupling constants of $SU(3)_c$, $SU(2)_L$ and $U(1)_Y$ are unified around the scale $v_2 \sim v_3$, since the SM gauge groups are embedded in a single vector $SU(5)$ subgroup of $SU(5)_1 \times SU(5)_2$. The stabilization of the VEVs is discussed in the next section. There, we obtain $v_2 \sim v_3 \sim \langle \phi \rangle$ in a natural way.

Let us mention a symmetry peculiar to $SU(5)_1 \times SU(5)_2$ models, which is quite useful to achieve the doublet-triplet splitting. Consider transformations with $\alpha_{24}^1 = -\alpha_{24}^2$, which we refer to as $U(1)^A_{24}$ transformations. Under $U(1)^A_{24}$ symmetry, $v_3$, $\bar{v}_3$, $v_2$ and $\bar{v}_2$ have charges of 4, $-6$, $-4$ and 6, respectively. A triplet and a doublet in 5 of $SU(5)_1$ have $U(1)^A_{24}$ charges of 2 and $-3$, while those of $SU(5)_2$ have $U(1)^A_{24}$ charges of $-2$ and +3.

### 4.3 Doublet-triplet splitting

In our discussion, we assume that quarks and leptons are unified into $\bar{5}$ and $10$ of $SU(5)_1$. We also assume that the doublet Higgses $H_u$ and $H_d$ are placed in 5 and $\bar{5}$ of $SU(5)_1$, which we denote by $H_1$ and $\bar{H}_1$:

$$H_1 = \begin{pmatrix} H^T_1 \\ H_u \end{pmatrix}, \quad \bar{H}_1 = \begin{pmatrix} \bar{H}^T_1 \\ H_d \end{pmatrix}. \quad (10)$$

With this arrangement, we can easily obtain yukawa couplings of quarks and leptons without any suppression, such as $H_1 \bar{10} 10$ and $H_2 \bar{5} 10$.

\[\text{11} \text{Here, the normalization of the rotation angle of } U(1)^A_{24} \text{ is } \sqrt{15}/30 \text{ times different from those of } \alpha_{24}^1 \text{s.}\]
Table 2: $U(1)_{24}^1$, $Z_{2nR}$ and $Z_{n+1}$ charges of Higgs quadratic terms. These charge assignments can be read off from Table 1.

|         | $H_1^T H_1^T / H_u H_d$ | $H_1^T H_2^T / H_u H_d$ | $H_2^T H_1^T / H_d H_d$ | $H_2^T H_2^T / H_d H_d$ |
|---------|--------------------------|--------------------------|--------------------------|--------------------------|
| $U(1)_{24}$ | 0 / 0                    | 4 / −6                   | −4 / 6                   | 0 / 0                    |
| $Z_{2nR}$  | 0                        | $r_3 − 2m$               | $2 − r_3$                | $2 − 2m$                |
| $Z_{n+1}$  | 0                        | $q_3 + m$                | $−q_3$                   | $m$                     |

Note that combinations $H_1^T H_1^T$ and $H_u H_d$ have identical charges under any symmetries. Thus, it is impossible to achieve hierarchy between their masses without fine-tuning if we assume that the triplet mass comes from the bi-linear term of $H_1^T$ and $H_1^T$. To avoid this problem, we are lead to introduce a pair of 5 and $\bar{5}$ of $SU(5)_2$, which we denote as $H_2$ and $\bar{H}_2$:

$$H_2 = \left(\begin{array}{c} H_2^T \\ H_2^D \end{array}\right), \quad \bar{H}_2 = \left(\begin{array}{c} \bar{H}_2^T \\ \bar{H}_2^D \end{array}\right). \quad (11)$$

The $U(1)_{24}$ charges of these Higgses are given by

$$H_1^T : 2, \quad \bar{H}_1^T : −2, \quad H_2^T : −2, \quad \bar{H}_2^T : 2, \quad H_u : −3, \quad H_d : 3, \quad H_2^D : 3, \quad \bar{H}_2^D : −3. \quad (12)$$

The charge assignment of those Higgses is given in Table 1. It should be noted that the mass terms of the Higgs multiplets are forbidden by $Z_{2nR}$ symmetry. In particular, the bi-linear term $H_1 \bar{H}_1$ is forbidden only by the $Z_{2nR}$ symmetry, and hence, it is identified with the doublet symmetry.

The $R$ symmetry is broken at the GUT scale by the VEVs of $\Phi$, $\bar{\Phi}$ and $\phi$. After spontaneous $R$ symmetry breaking, the mass terms of Higgs multiplets are generated via the couplings to those VEVs. From the charge assignments shown in Table 1, the following Higgs bi-linear terms in the superpotential are allowed,

$$W = H_1 \bar{\Phi}_3 \bar{H}_2 + H_2 \Phi_3 \bar{H}_1 + \phi^m H_2 \bar{H}_2, \quad (13)$$

which lead to the GUT scale masses to Higgs fields except for $H_u$ and $H_d$. It should be emphasized that the Higgs bi-linear term $H_1 \bar{H}_1$ does not appear due to the $Z_{n+1}$ symmetry.
in spite of the vanishing charges of $H_1 \bar{H}_1$. On the other hand, the Higgs bi-linear term $H_2 \bar{H}_2$ proportional to $\phi^m$ is allowed by the $Z_{n+1}$ symmetry, which leads to the mass of $O(v)$ or $O(v^2)$ for either $m = 1$ or $m = 2$.

The $U(1)_{A_{24}}^A$ symmetry also plays an important role in the doublet-triplet splitting. First, let us remember that the order parameters $v_3$ and $\bar{v}_3$ have $(U(1)_{A_{24}}, Z_{2nR}, Z_{n+1})$ charges of $(4, r_3, q_3)$ and $(-4, 2 + 2m - r_3, -m - q_3)$, respectively. Thus, the triplet mass terms $v_3 H_1^T \bar{H}_1^T$ and $\bar{v}_3 H_1^T \bar{H}_1^T$ are allowed by symmetries (see Table 2). The doublet mass terms such as $v_3 H_2^D H_d$ and $\bar{v}_3 H_u \bar{H}_2^D$ are on the other hand forbidden by $U(1)_{A_{24}}^A$ symmetry, although they can never be forbidden by $Z_{2nR}$ nor $Z_{n+1}$ symmetries.

From the above arguments, we see that both $U(1)_{A_{24}}^A$ and $Z_{n+1}$ symmetries play the roles of triplet symmetries, where the doublet mass term $H_u H_d$ are neutral under those symmetries. That is, due to the vanishing charges of $H_u H_d$ under the $U(1)_{A_{24}}^A$ and $Z_{n+1}$ symmetries, couplings to $v_3$, $\bar{v}_3$, $v_2$, $\bar{v}_2$ and $\langle \phi \rangle$ are highly surpressed, while other components in the Higgs sector obtain large masses. The doublet mass, i.e. the $\mu$-term is eventually generated via the Planck-suppressed interactions to the order parameters of the $R$ symmetry with charge 2 but neutral under the triplet symmetries,

$$W = \phi^{n+1} H_1 \bar{H}_1 , \quad v^n \phi H_1 \bar{H}_1 . \quad (14)$$

It should be emphasized that the scales of $\langle \phi \rangle^{n+1}$ and $v^n \langle \phi \rangle$ are nothing but the one of the VEV of the superpotential, $\langle W \rangle$, and hence, the doublet mass of the gravitino mass is naturally achieved as expected in the solution to the $\mu$-problem in the MSSM using the $R$ symmetry breaking [17,18].

Several comments are in order. In the above discussion, we have focused on the suppression of the bi-linear term $H_1 \bar{H}_1$. It should be noted, however, that the mass term of $H_u H_d$ could be induced by mixing of them with $H_2^D$ and $\bar{H}_2^D$. In fact, the $U(1)_{A_{24}}^A$ symmetry alone does not forbid mass terms proportional to $\bar{v}_2 H_u \bar{H}_2^D$ and $v_2 H_2^D H_d$. In the model discussed in the next section, we have checked that mass terms of $H_u \bar{H}_2^D$ and $H_2^D H_d$ are sufficiently suppressed due to charge-mismatching between these bilinear terms and order parameters of the $R$ symmetry breaking.

So far, we have given GUT scale masses to Higgs the multiplets other than $H_u$ and $H_d$. Still, it is necessary to consider masses of GUT breaking fields $\Phi_3$, $\Phi_2$, $\Phi_3$ and $\Phi_2$. 

13
We discuss this topic in the next section along with the unification scale and the decay rate of protons.

### 4.4 Bottom-tau unification

Here, we briefly mention the unification of down-quark yukawa couplings and charged-lepton yukawa couplings. As we have mentioned, we consider a model such that the MSSM doublet Higgses are embedded in $\mathbf{5}$ and $\mathbf{\bar{5}}$ of $SU(5)_1$, and quarks and leptons are unified into $\mathbf{5}$ and $\mathbf{10}$ of $SU(5)_1$. Then down-quark yukawa couplings and charged-lepton yukawa couplings must be unified at the GUT scale. In Fig. 2 we show the renormalization group running of the bottom yukawa coupling $Y_b$ and the tau yukawa coupling $Y_\tau$ in the MSSM. Here, we assume that SUSY particles are as heavy as 1 TeV. It can be seen that $Y_\tau > Y_b$ around that GUT scale, which is inconsistent with the unification of yukawa couplings. The discrepancy becomes larger for a high scale SUSY breaking models where the gaugino masses are kept in the TeV region (see e.g. [41]).

This problem can be easily mended by introducing $\mathbf{5}$ and $\mathbf{\bar{5}}$ of $SU(5)_2$, which we denote as $\mathbf{5}_2$ and $\mathbf{\bar{5}}_2$, respectively. Consider the following superpotential,

$$W = M \mathbf{5}_2 \mathbf{\bar{5}}_2 + \lambda' \mathbf{\bar{5}} \Phi_3 \mathbf{5}_2 + y \bar{H}_1 \mathbf{10} \mathbf{\bar{5}},$$  \hspace{1cm} (15)

where $M$, $\lambda'$ and $y$ are constants.\(^{12}\) This superpotential is always allowed with appropriate choice of charges of $\mathbf{5}_2$ and $\mathbf{\bar{5}}_2$. Here, we consider only the third generation of $\mathbf{10}$ and $\mathbf{\bar{5}}$, for simplicity.

After the GUT breaking, the triplet in $\mathbf{\bar{5}}$ mixes with that in $\mathbf{\bar{5}}_2$. The right-handed bottom quark we observe in low energy scales is a linear combination of them. Just below the GUT scale, the bottom yukawa coupling is smaller than the tau yukawa coupling by a factor of $O(1)$, if $M = O(\langle \nu_3 \rangle \)\(^{13}\). This is consistent with the running of yukawa couplings shown in Fig. 2. Similarly, one can arrange $O(1)$ differences between down-quark yukawa couplings and charged-lepton yukawa couplings of the first and the second generations, by mixing of triplets in $\mathbf{\bar{5}}$ of the first and the second generations with the triplet in $\mathbf{\bar{5}}_2$.

\(^{12}\) One may replace the constant $M$ with fields which obtain GUT scale VEVs.

\(^{13}\) A similar mechanism to split the yukawa couplings can be implemented in a simple $SU(5)$ GUT model.
Figure 2: Running of the bottom yukawa coupling $Y_b$ and the tau yukawa coupling $Y_\tau$ for $\tan\beta = 5$ (left) and $\tan\beta = 50$ (right). The x-axis, $Q$, denotes the renormalization scale. The discrepancy between $Y_\tau$ and $Y_b$ becomes larger for larger soft scalar masses.

5 Mass spectrum, unification and proton decay

In this section, we study models outlined in the previous section in detail. We present a model in which masses of $\Phi_3$, $\Phi_2$, $\bar{\Phi}_3$ and $\bar{\Phi}_2$ are sufficiently large. We show the mass spectrum and estimate unification scales as well as decay rates of the proton in the model.

5.1 Mass spectrum

In our model, we take $n = 6$, and hence, the discrete symmetries are $Z_{12R}$ and $Z_7$. In Table 3, we show the matter content and the charge assignment. With this charge assignment, the masses of Higgs multiplets are given by the one in previous section with $m = 2$. In addition to the fields introduced in the previous section, we introduce gauge singlet fields $\bar{\phi}$, $Z_1$, $Z_2$, $Z_3$, $Z_4$ and a spurious field $\bar{v}^6$. We assume that $v^6 \sim \bar{v}^6$, which is natural since they have opposite charges with each other.
Table 3: Matter contents and charge assignment.

|       | $\Phi_3$ | $\Phi_3$ | $\Phi_2$ | $\Phi_2$ | $\phi$ | $\phi$ | $v^a$ | $\bar{v}^b$ | $Z_1$ | $Z_2$ | $Z_3$ | $Z_4$ |
|-------|----------|----------|----------|----------|--------|--------|--------|-------------|-------|-------|-------|-------|
| $Z_{12R}$ | -4       | -2       | 6        | 0        | 2      | 2      | 0      | 0           | -2    | -2    | 6     | 2     |
| $Z_7$   | 0        | 2        | 4        | -2       | 1      | -1     | -1     | 1           | 1     | 1     | 1     | 2     |

|       | $H_1$ | $H_1$ | $H_2$ | $H_2$ | $5$ | $10$ |
|-------|-------|-------|-------|-------|-----|------|
| $Z_{12R}$ | 0     | 0     | 6     | -8    | 1   | 1    |
| $Z_7$   | 0     | 0     | 0     | -2    | 0   | 0    |

The superpotential which ensure the VEV pattern in Eq. (9) is given by,

$$W = \bar{\phi}(\Phi_3\Phi_3\Phi_3\Phi_2\Phi_2 + \bar{v}^6)$$

$$+ Z_3(\Phi_3\Phi_2) + (\Phi_3\Phi_2\Phi_3\Phi_3) + (\Phi_3\Phi_2\Phi_3\Phi_2) + (\Phi_3\Phi_2)(\Phi_2\Phi_2),$$

$$+ (\Phi_2\Phi_3\Phi_2\Phi_3\Phi_3) + (\Phi_2\Phi_3\Phi_2\Phi_3\Phi_2) + (\Phi_3\Phi_3\Phi_2\Phi_2\Phi_2)\phi^2$$

$$+ Z_1(\Phi_2\Phi_3) + (Z_1 + Z_2)(\Phi_3\Phi_3\Phi_3\Phi_3)$$

$$+ Z_4 Z_3(\Phi_3\Phi_3) + Z_4 Z_3(\Phi_2\Phi_2) + Z_4(\Phi_3\Phi_3)(\Phi_3\Phi_3) + Z_4(\Phi_2\Phi_2)(\Phi_3\Phi_3)$$

$$+ Z_4(\Phi_2\Phi_2)(\Phi_2\Phi_2) + Z_4(\Phi_3\Phi_3\Phi_3\Phi_3) + Z_4(\Phi_2\Phi_2\Phi_2\Phi_2)$$  \text{(16)}

where we omit coupling constants, which we assume to be $O(1)$ in the Planck unit. Here,

$$(\Phi_3\Phi_3\Phi_2\Phi_2) \equiv \epsilon^{abcde}\epsilon_{ABCDEF}\Phi_3^{Aa}\Phi_3^{Bb}\Phi_3^{Cc}\Phi_2^{Dd}\Phi_2^{Ee},$$

$$(\Phi\Phi\Phi) \equiv \Phi^{Aa}\Phi^{Bb}\ldots\Phi^{Ee},$$ \text{(17)}

where lower indices $a,b,\ldots (=1-5)$ and $A,B,\ldots (=1-5)$ are indices of the fundamental representation of $SU(5)_1$ and $SU(5)_2$, respectively. Upper indices are those of the anti-fundamental representation. Here, we have shown only relevant terms for the later discussion and omitted several terms which are allowed by symmetries. Our conclusions are not changed, even if we includes those terms.

The $F$ term condition of $\bar{\phi}$ requires $\Phi_3$ and $\Phi_2$ to obtain their VEVs.\textsuperscript{14} Along with the $F$ term condition of $\phi$ and the $D$ term condition, the $F$ term conditions of $Z_{1,2,4}$ and $\Phi'$s require the VEVs of the form in Eq. (9) with $\nu_3 = \bar{\nu}_3 \sim \bar{\nu}_2 = \bar{\nu}_2 \equiv v_G \sim \bar{v}^{6/5}$, $\langle Z_1 \rangle \sim v^2\bar{v}_G^3$, $\langle Z_2 \rangle \sim v^2$ and $\langle Z_3 \rangle \sim v^2$.\textsuperscript{15} Here, the singlet fields $Z_{1,2}$ cancel the $F$ terms of $\Phi'$s. Note

\textsuperscript{14}Since $\bar{\phi}^7$ is allowed by symmetry, there is a gauge symmetric where $\bar{\phi} \sim \bar{v}$ and $\Phi = \bar{\Phi} = \bar{0}$, in addition to the $SU(5)_1 \times SU(5)_2$ branch, i.e. $\Phi = \bar{\Phi} \neq 0$. We choose the symmetry breaking branch.

\textsuperscript{15}It should be noted that superpotential terms such as $\phi^2 Z_{1,2}^3$ are also allowed by symmetries. In the
that the VEVs of Φ and ¯Φ are as large as ⟨φ⟩. Thus, the origin of the GUT scale and the gravitino mass are interrelated with each other, which is an interesting feature of this example.

Let us consider the masses of SU(3)_c × SU(2)_L × U(1)_Y charged particles in Φ, Φ, Φ and Φ. In the unitarity gauge, their charged components are decomposed as

\[
\Phi_3 = \left( v_3 + O_3 \ X \ T_3 \right), \quad \Phi_3 = \left( \bar{v}_3 + O_3 \ X \ T_3 \right), \quad \Phi_2 = \left( O_2 \ Y \ v_2 + T_2 \right), \quad \Phi_2 = \left( O_2 \ Y \ v_2 + T_2 \right),
\]

where SU(3)_c × SU(2)_L × U(1)_Y charges are given by

\[
O : (8,1)_0, \quad T : (1, 3)_0, \quad X : (3, 2)_{-5/6}, \quad Y : (\bar{3}, 2)_{5/6}.
\]

The second lines of superpotential in Eq. [16] give the masses of O(v^2_G) to O_2, T_3T_2 and XY. The masses of O, O, X, Y and T_3 are generated from the third line of the superpotential. The first and the second term in the third line give O(v^4_G) masses to O_2 and T_3, respectively. The third term of the third line gives an O(v^3_G v^2) ∼ O(v^{14/3}_G) mass to X Y.

Let us summarize masses of charged particles lighter than the GUT scale v_G:

\[
O(v^{5/3}_G) : H^D_2, \quad \bar{H}^D_2
\]

\[
O(v^2_G) : O_2, \quad \bar{O}_2, \quad T_3, \quad T_2, \quad X, \quad Y
\]

\[
O(v^4_G) : O_2, \quad \bar{T}_3
\]

\[
O(v^{14/3}_G) : X, \quad \bar{Y}.
\]

(20)

Note that relatively light fields, O_2, X, Y and \bar{T}_3, form a GUT complete multiplet 24 in terms of a single SU(5) group, and hence, the GUT unification is maintained. We have also checked that all the gauge singlet fields below the GUT scale obtain sizable masses. Since all charged fields obtain masses, the symmetry breaking branch is found to be a stable vacuum. Besides, since all the masses are larger than the size of the (gravity mediated) SUSY breaking soft masses of O(v^7), the vacuum is even stable against the SUSY breaking effects.

presence of those terms, the missing VEV pattern in Eq. [9] is destabilized, although SU(3)_c × SU(2)_L × U(1)_Y remains unbroken. Such destabilization potentially leads to too large doublet Higgs mass and/or too large VEV of the superpotential. In our model, we have checked that the missing part of the VEV of Φ’s are destabilized by \(\delta \Phi_3 = O(v^{10}/v^3_G)\) and \(\delta \bar{\Phi}_3 = O(v^8/v^7_G)\), which leads to the doublet mass of O(v^{16}/v^7_G) and the VEV of the superpotential of O(v^{10}). Thus, those terms causes no serious problems.
Table 4: Mass spectrum of charged particles. We assume $v^6 = \bar{v}^6$, $v_G \sim v^{5/6}$. In the parentheses, we take the gravitino masses 100 TeV.

| Mass (GeV)     | Mass (GeV)     | Mass (GeV)     |
|----------------|----------------|----------------|
| $(8, 1)_0$     | $v_G^2 (10^{14})$ | $(1, 3)_0$     |
| $(8, 1)_0$     | $v_G^2 (10^{14})$ | $(1, 3)_0$     |
| $(8, 1)_0$     | $v_G^4 (10^{10})$ | $(1, 3)_0$     |
| $(3, 2)_{-6/5}$ | $v_G^2 (10^{14})$ | $(3, 2)_{-6/5}$|
| $(3, 2)_{-6/5}$ | $v_G^2 (10^{14})$ | $(3, 2)_{-6/5}$|
| $(3, 2)_{-6/5}$ | $v_G^4 (10^{10})$ | $(1, 2)_{1/2}, (\bar{1}, 2)_{-1/2}$|
| $v_G^{4/3} (10^8)$ | $v_G^{7/3} (10^{14})$ |

5.2 Unification scale and proton decay

Unification scale

In the left panel of Fig. 3, we show the one-loop renormalization group running of the gauge coupling constants of $SU(3)_c$, $SU(2)_L$ and $U(1)_Y$. Here, we assume that $v_3 = v_2 = 1 \times 10^{16}$ GeV to determine the masses of charged particles. We also assume that the MSSM gaugino masses are 1 TeV, the MSSM scalar masses are 100 TeV, and the Higgsino mass is 100 TeV, which is the case of typical high scale SUSY breaking models. The masses of the heavy fields in Eq. (20) are summarized in Table 4.

In the right panel of Fig. 3 we show the one-loop renormalization group running of the gauge couplings constants of $SU(5)_1$ and $SU(5)_2$ from $1 \times 10^{16}$ GeV to the Planck scale. We take $g_{SU(5)_1} = g_{SU(5)_2}$ at $1 \times 10^{16}$ GeV. Here, we include the contribution of $5_2$ and $\bar{5}_2$ which are introduced to solve the problem of the unification of yukawa couplings. One can see that both gauge coupling constants are perturbative below the Planck scale.

Proton decay

Now, we are at the position to predict the proton lifetime. Let us first consider the proton decay by dimension five operators [40]. The Planck-suppressed dimension five operators such as,

$$W = 10 \, 10 \, 10 \, 5, \quad (21)$$

Since $SU(5)_2$ is asymptotically free, we might safely assume $g_{SU(5)_1} \ll g_{SU(5)_2}$ without spoiling the perturbativity up to the Planck scale.
Figure 3: Running of the gauge coupling constants. We assume that $v_3 = v_2 = 2 \times 10^{16}$ GeV, MSSM gaugino masses are 1 TeV, MSSM scalar masses are 100 TeV, and the Higgsino mass is 100 TeV. The left panel show the running in the low energy effective theory below the GUT scale. The right panel show the running above the GUT scale.

are forbidden due to the discrete $R$ symmetry, i.e. the doublet symmetry. However, below the GUT scale, the exchange of the triplets $H_1^c$ and $\bar{H}_1^c$ induces a dimension five operator:

$$W = H_1 \Phi_3 \bar{H}_2 + \bar{H}_1 \Phi_3 H_2 + \phi^m H_2 \bar{H}_2 + y_{IJ} H_1 \bar{H}_1 10^I \bar{10}^J + y'_{IJ} H_1 5^i 10^J$$

where $i, I (= 1-3)$ denote generation indices. The decay rate of $p \rightarrow K^+ \bar{\nu}$ induced by the dimension five operator is roughly given by

$$\Gamma(p \rightarrow K^+ \bar{\nu})^{-1} \approx 10^{39} \text{ years} \times \sin^2 2\beta \left( \frac{M_{\text{SUSY}}}{100 \text{ TeV}} \right)^2 \left( \frac{M_{\text{eff}}}{10^{18} \text{ GeV}} \right)^2,$$

where $M_{\text{SUSY}}$ denotes masses of SUSY particles. In Fig. [4], we show the relation between the gravitino mass $m_{3/2}$ and the effective triplet mass $M_{\text{eff}}^c$.

The figure shows that $M_{\text{eff}}^c$ is sufficiently large and hence the models are consistent with the current 90% C.L. limit, $\Gamma(p \rightarrow K^+ \bar{\nu})^{-1} > 4.0 \times 10^{33}$ years [44].

It should be noted that the $\mu$-term and the dimension five proton decay operators are closely related in terms of symmetry. Assuming the standard embedding of the Higgs multiplets and the quarks and the leptons, the charge assignment of the $\mu$-term ($Q_\mu$) is forbidden due to the discrete $R$ symmetry, i.e. the doublet symmetry. However, below the GUT scale, the exchange of the triplets $H_1^c$ and $\bar{H}_1^c$ induces a dimension five operator:

$$W = H_1 \Phi_3 \bar{H}_2 + \bar{H}_1 \Phi_3 H_2 + \phi^m H_2 \bar{H}_2 + y_{IJ} H_1 \bar{H}_1 10^I \bar{10}^J + y'_{IJ} H_1 5^i 10^J$$

where $i, I (= 1-3)$ denote generation indices. The decay rate of $p \rightarrow K^+ \bar{\nu}$ induced by the dimension five operator is roughly given by

$$\Gamma(p \rightarrow K^+ \bar{\nu})^{-1} \approx 10^{39} \text{ years} \times \sin^2 2\beta \left( \frac{M_{\text{SUSY}}}{100 \text{ TeV}} \right)^2 \left( \frac{M_{\text{eff}}}{10^{18} \text{ GeV}} \right)^2,$$

where $M_{\text{SUSY}}$ denotes masses of SUSY particles. In Fig. [4], we show the relation between the gravitino mass $m_{3/2}$ and the effective triplet mass $M_{\text{eff}}^c$. The figure shows that $M_{\text{eff}}^c$ is sufficiently large and hence the models are consistent with the current 90% C.L. limit, $\Gamma(p \rightarrow K^+ \bar{\nu})^{-1} > 4.0 \times 10^{33}$ years [44].

It should be noted that the $\mu$-term and the dimension five proton decay operators are closely related in terms of symmetry. Assuming the standard embedding of the Higgs multiplets and the quarks and the leptons, the charge assignment of the $\mu$-term ($Q_\mu$)
under a low energy symmetry is related to that of the dimension five operators ($Q_{\text{dim5}}$) by $Q_\mu = Q_{\text{dim5}}$ for non-$R$ symmetries and $Q_\mu = 4 - Q_{\text{dim5}}$ for $R$ symmetry. Thus, the absence of the $\mu$-term by a symmetry means the absence of dimension five proton decay operators. In our model, however, the doublet symmetry which leads to an effective low energy symmetry forbidding the $\mu$-term is spontaneously broken at the GUT scale. Therefore, the dimension five proton decay operators can be generated even if the doublet Higgs mass is suppressed by the triplet symmetries.

Next, we consider the proton decay by dimension six operators, namely by the exchange of GUT gauge bosons \cite{5,43}. The decay rate of $p \rightarrow \pi^0 + e^+$ by dimension six operators is roughly given by,

$$\Gamma(p \rightarrow \pi^0 + e^+)^{-1} \approx 10^{35} \text{ years} \left(\frac{v_G}{10^{16}\text{GeV}}\right)^4,$$

where $v_G$ is the vacuum expectation value of GUT breaking fields, $v_G \sim v_3 \sim v_2$. In our model, the decay rate is consistent with the current 90\% C.L. limit, $\Gamma(p \rightarrow \pi^0 + e^+)^{-1} > 1.3 \times 10^{34} \text{ years}$ \cite{44}.

### 6 Conclusions and Discussion

In this paper, we have revisited the long-standing problem of SUSY GUT models, the doublet-triplet splitting problem. We payed particular attention to the consistency of the low energy symmetry (doublet symmetry) which controls the size of the $\mu$-term to
GUT models. By using the anomaly matching conditions of the doublet symmetry, we find that the low energy symmetry cannot be embedded in GUT models with automatic gauge coupling unification unless the low energy symmetry is broken at the GUT scale. It should be noted that the above no-go theorem applies even to GUT models based on product gauge groups as long as the coupling unification is automatic.

We also proposed a new prescription to embed the low energy doublet symmetry to the GUT models while evading the no-go theorem. There, the doublet symmetry is spontaneously broken at the GUT scale. Since order parameter of the doublet symmetry are also charged under other symmetries (we call them triplet symmetries), the doublet Higgses do not obtain a mass of the GUT scale. The triplet Higgses (and other unwanted fields), on the other hand, are charged under the triplet symmetry so that they obtain much heavier masses than the doublet Higgses. As a notable feature of this mechanism, the less charged fields obtain more suppress masses, i.e., the have-nots get no masses at the GUT scale.

We also found a similar no-go theorem on the $R$ symmetry, so that $R$ symmetry should be broken at the GUT scale. There again, the $R$ symmetry is effectively preserved as a good approximate symmetry below the GUT scale, if the order parameters are charged under other symmetries.

As a demonstration, we consider an $SU(5)_1 \times SU(5)_2$ GUT model where the doublet symmetry is $R$ symmetry. The $\mu$-term is generated via the coupling of the doublet Higgses to $R$ symmetry breaking of the order of the VEV of the superpotential, and hence, the doublet Higgs obtains the mass of the order of the gravitino mass. This shows that the successful MSSM such as the pure gravity mediation model can be consistently extended to GUT models with an automatic coupling unification.

One of the interesting observations of this example is a connection between the GUT scale and the size of the gravitino mass. As we discussed in Sec. 5, the origins of the GUT scale and the scale of the spontaneous $R$ symmetry breaking is naturally unified while the VEV of the superpotential (i.e. the gravitino mass) is much suppressed due to triplet symmetries. Thus, for a given GUT scale, the required SUSY breaking scale to obtain a flat-universe by fine-tuning is no more free parameters. This feature might shed light on the question why the SUSY breaking scale is not in a range such that the
electroweak symmetry breaking is naturally induced by the SUSY breaking, although we have no definite answers on this question.

Several comments are in order. In many models, the low-energy symmetry which controls the size of the $\mu$-term is not anomaly-free.\footnote{Here, we now discuss the total anomaly including not only the Higgs sector but also gauginos, quarks and leptons.} Thus, those symmetries are thought to be difficult to originate from exact gauge symmetries. In our mechanism, on the other hand, the doublet symmetry is spontaneously broken at the GUT scale. Hence, the failure in the anomaly free conditions at the low energy does not necessarily mean that the low-energy symmetry cannot originate from exact gauge symmetries.

The low-energy symmetry which suppresses the $\mu$-term also suppresses the dimension five proton decay operators. In our mechanism, however, the doublet symmetry is broken at the GUT scale, and hence, the dimension five proton decay operators are not necessarily highly suppressed. In fact, as we have discussed in Sec.\footnote{Here, we now discuss the total anomaly including not only the Higgs sector but also gauginos, quarks and leptons.} the sizable (but acceptable) dimension five proton decay operators appear. It should be noted that the relative sizes of the dimension six proton decay operators and the dimension five proton decay operators can be far different from the minimal (and fine-tuned) $SU(5)$ GUT model, with which we might be able to distinguish our mechanisms from the minimal $SU(5)$ model.
