The classical Denjoy-Young-Saks theorem on Dini derivatives of arbitrary functions $f : \mathbb{R} \to \mathbb{R}$ was extended by U.S. Haslam-Jones (1932) and A.J. Ward (1935) to arbitrary functions on $\mathbb{R}^2$. This extension gives the strongest relation among upper and lower Hadamard directional derivatives $f_+^H(x,v)$, $f_-^H(x,v)$ ($v \in X$) which holds almost everywhere for an arbitrary function $f : \mathbb{R}^2 \to \mathbb{R}$. Our main result extends the theorem of Haslam-Jones and Ward to functions on separable Banach spaces.

Keywords: Hadamard upper and lower directional derivatives, Denjoy-Young-Saks theorem, separable Banach space, Hadamard differentiability, Fréchet differentiability, Hadamard subdifferentiability, Fréchet subdifferentiability, $\tilde{C}$-null set, $\Gamma$-null set, Aronszajn null set

1. Introduction

The classical Denjoy-Young-Saks theorem gives the strongest relation between Dini derivatives $D^+f$, $D_-f$, $D_+f$, $D_-f$, which holds for an arbitrary functions almost everywhere. It reads as follows.

**Theorem DYS.** Let $f$ be an arbitrary real function on $\mathbb{R}$. Then, at almost all $x \in \mathbb{R}$, one from the following assertions holds:

(i) $f'(x) \in \mathbb{R}$ exists,

(ii) $D^+f(x) = D^-f(x) = \infty$ and $D_+f(x) = D_-f(x) = -\infty$,

(iii) $D^+f(x) = \infty$, $D_-f(x) = -\infty$, and $D_+f(x) = D^-f(x) \in \mathbb{R}$,

(iv) $D^-f(x) = \infty$, $D_+f(x) = -\infty$, and $D_-f(x) = D^+f(x) \in \mathbb{R}$.

A natural generalization of Denjoy-Young-Saks theorem to measurable functions on $\mathbb{R}^2$ was proved by U.S. Haslam-Jones [6] and was extended to arbitrary functions on $\mathbb{R}^2$ by A.J. Ward [18]. This generalization works with upper and lower directional derivatives, however it is not possible to use the usual ("Dini") directional derivatives (even for continuous functions, see [3]), but it is necessary to work with Hadamard upper and lower directional derivatives $f_+^H(x,v)$ and $f_-^H(x,v)$ (see Subsection 2.2 below for definitions) which were defined (possibly first time) in [6] under the name "directed upper and lower derivatives". (Haslam-Jones considered their definition as the fundamental idea of the article, see [6, p. 121].)

The theorem of Haslam-Jones and Ward (see [6, 13. Summary, p. 31] and [18, Theorem V, p. 352]) can be reformulated in the following way.

**Theorem HW.** Let $f$ be an arbitrary real function on $X = \mathbb{R}^2$. Then, at almost all $x \in X$, one from the following assertions holds:

(i) $f$ is Hadamard differentiable at $x$, 

Every cone-monotone function on $\mathbb{R}^n$ is almost everywhere differentiable.

Indeed, (1.1) is the well-known Stepanov theorem and (1.2) was proved in [4].

For generalizations (using Hadamard differentiability and $\mathcal{C}$-null sets) of (1.1) and (1.2) to separable Banach spaces see [21, Theorem 3.4 ] and [5, Corollary 17].

Generalizations (using Fréchet differentiability and $\Gamma$-null sets) of (1.1) and (1.2) to $c_0$ (and similar spaces) were observed in [23].

Note also that an incomplete version (see Remark 5.6 below) of Theorem HW (which does not imply the linearity of $L$ in Theorem HW (iii),(iv)) was proved by S. Saks ([15, Th. 7, p. 238]) before [18]. A similar incomplete version (see Remark 5.6 below) of our Theorem 5.3 follows from a result of [13]. Note that D. Preiss in [13] works with another $\sigma$-ideal of null sets, which is smaller (and possibly strictly smaller) than the $\sigma$-ideal $\mathcal{C}$.

Finally note that the present paper is a continuation of author’s articles [21], [22], [23] which were motivated by the article [7] by A.D. Ioffe, in which the relations among directional Hadamard derivatives of arbitrary functions on separable Banach spaces are investigated. A result of [7] (see Theorem I from Preliminaries) is one from ingredients of our proof.

The article is organized as follows. In Section 2 we recall definitions of the main notions and some their properties. The core of the article is the first step of the proof of Lemma 3.2 of Section 3, which is the only technical part of the article. This proof is an essential modification of the proof of [5, Theorem 15].

(ii) $f_H^+(x,v) = \infty$ for each $v \in X$ and $f_H^+(x,v) = -\infty$ for each $v \in X$,

(iii) $f_H^-(x,v) = \infty$ for each $v \in X$ and $L(v) := f_H^-(x,v) \in X^*$,

(iv) $f_H^-(x,v) = -\infty$ for each $v \in X$ and $L(v) := f_H^+(x,v) \in X^*$.

We show (Theorem 5.3) that this result holds in any separable Banach space $X$ if “at almost all points” means “at all points except for a set from $\mathcal{C}$”. (Note that each set from the $\sigma$-ideal $\mathcal{C}$ is both Haar null and $\Gamma$-null.)

We emphasize that the condition (i) above holds (in an arbitrary Banach space $X$) if and only if $f_H^+(x,v) = f_H^-(x,v)$ for each $v \in X$ and $L(v) := f_H^+(x,v) \in X^*$, and so Theorem HW and Theorem 5.3 give a relation among Hadamard directional derivatives $f_H^+(x,v), f_H^-(x,v) (v \in X)$ which holds a.e. for an arbitrary function on $X$. Moreover (see Remark 5.7) it is the strongest relation of this type.

S. Saks ([16, Theorem 14.2]) inferred Theorem HW from results (due to F. Roger) on the contingents (= tangent Bouligand cones) of arbitrary subsets in $\mathbb{R}^3$. His formulation of Theorem HW is formally very different from that of [6] and [18]; in particular he did not used explicitly “directed derivatives”. Further, his formulation works with Fréchet differentiability and Fréchet subgradients (supergradients). So his formulation of Theorem HW is not equivalent to that of [6] and [18] in infinite-dimensional spaces (although it is easily equivalent in $\mathbb{R}^n$). However, we show (Theorem 5.1) that also this Saks’ “stronger formulation” extends to some infinite-dimensional spaces. Namely, it is true, if “almost all” is taken in the sense of $\Gamma$-null sets and $X$ is a separable Banach space, in which J. Lindenstrauss and D. Preiss [8] proved the “ $\Gamma$-a.e. Rademacher theorem” for Fréchet differentiability of real functions; e.g. if

(i) $X$ is a subspace of $c_0$, or

(ii) $X = C(K)$, where $K$ is a separable compact space, or

(iii) $X$ is the Tsirelson space.

A.J. Ward ([18, p. 347]) claims that his arguments can be used to prove Theorem HW in $\mathbb{R}^n$, but “to avoid confusion of quasi-geometrical detail, however, this extension has not been made” and it seems that no proof of this extension can be found in the literature. However, it is well-known for a long time that the following interesting special cases of Theorem HW hold in $\mathbb{R}^n$:

(1.1) Every $f$ on $\mathbb{R}^n$ is differentiable at almost all points at which it is Lipschitz.

(1.2) Every cone-monotone function on $\mathbb{R}^n$ is almost everywhere differentiable.

Note also that an incomplete version (see Remark 5.6 below) of Theorem HW (which does not imply the linearity of $L$ in Theorem HW (iii),(iv)) was proved by S. Saks ([15, Th. 7, p. 238]) before [18]. A similar incomplete version (see Remark 5.6 below) of our Theorem 5.3 follows from a result of [13]. Note that D. Preiss in [13] works with another $\sigma$-ideal of null sets, which is smaller (and possibly strictly smaller) than the $\sigma$-ideal $\mathcal{C}$.

Finally note that the present paper is a continuation of author’s articles [21], [22], [23] which were motivated by the article [7] by A.D. Ioffe, in which the relations among directional Hadamard derivatives of arbitrary functions on separable Banach spaces are investigated. A result of [7] (see Theorem I from Preliminaries) is one from ingredients of our proof.

The article is organized as follows. In Section 2 we recall definitions of the main notions and some their properties. The core of the article is the first step of the proof of Lemma 3.2 of Section 3, which is the only technical part of the article. This proof is an essential modification of the proof of [5, Theorem 15].
The proof of Section 4 is essentially well-known. Indeed, it is “one-half” of Malý’s proof from [10], which shows that each Rademacher theorem (for real functions) easily implies a corresponding Stepanov theorem.

Section 5 contains the main results. Their proofs follow easily from results of Sections 3 and 4 and the above mentioned Ioff’e’s result.

2. Preliminaries

2.1. Basic notation. In the following, by a Banach space we mean a real Banach space. If $X$ is a Banach space, we set $S_X := \{ x \in X : \| x \| = 1 \}$. The symbol $B(x, r)$ will denote the open ball with center $x$ and radius $r$. The characteristic function of a set $C \subset X$ is denoted by $\chi_C$.

Let $X$ be a Banach space, $x \in X$, $v \in S_X$ and $\delta > 0$. Then we define the open cone $C(x, v, \delta)$ as the set of all $y \neq x$ for which $\| v - \frac{y - x}{\| y - x \|} \| < \delta$.

The following easy inequality is well known (see e.g. [11, Lemma 5.1]):

$$\text{(2.1) if } u, w \in X \setminus \{ 0 \}, \text{ then } \left\| \frac{u}{\| u \|} - \frac{w}{\| w \|} \right\| \leq \frac{2}{\| u \|} \| u - w \|. \quad (2.1)$$

2.2. Directional derivatives, derivatives and subgradients. In this subsection we suppose that $f$ is a real function defined on an open subset $G$ of a Banach space $X$.

We say that $f$ is Lipschitz at $x \in G$ if $\limsup_{y \to x} \frac{|f(y) - f(x)|}{\| y - x \|} < \infty$.

The Hadamard directional and one-sided directional derivatives of $f$ at $x \in G$ in the direction $v \in X$ are defined respectively by

$$f'_H(x, v) := \lim_{z \to v, t \to 0} \frac{f(x + tz) - f(x)}{t} \quad \text{and} \quad f'_H(x, v) := \lim_{z \to 0^+} \frac{f(x + tz) - f(x)}{t}. \quad (2.2)$$

Following [7], we denote the upper and lower Hadamard one-sided directional derivatives of $f$ at $x$ in the direction $v$ by

$$f^+H(x, v) := \limsup_{z \to v, t \to 0^+} (f(x + tz) - f(x))t^{-1} \quad \text{and} \quad f^-H(x, v) := \liminf_{z \to v, t \to 0^+} (f(x + tz) - f(x))t^{-1}. \quad (2.3)$$

Obviously,

$$f^+H(x, v) > 0 \quad \text{and} \quad f^-H(x, v) < 0, \text{ if } v \neq 0 \quad \text{and} \quad \lambda > 0. \quad (2.4)$$

Further (see [12, the proof of Proposition 4.4]), the following easy fact holds.

**Lemma 2.1.** The following assertions are equivalent.

(i) $\liminf_{y \to x} \frac{f(y) - f(x)}{\| y - x \|} > -\infty$,

(ii) $f'_H(x, 0) = -\infty$,

(iii) $f'_H(x, 0) = 0$.

The usual modern definition of the Hadamard derivative is the following:

A functional $L \in X^*$ is said to be a Hadamard derivative of $f$ at a point $x \in X$ if

$$\lim_{t \to 0} \frac{f(x + tv) - f(x)}{t} = L(v) \quad \text{for each } v \in X$$

and the limit is uniform with respect to $v \in C$, whenever $C \subset X$ is a compact set. In this case we set $f'_H(x) := L$.

It is well-known (see [17], cf. [12, Exercise 1, p. 132]) that $L \in X^*$ is a Hadamard derivative of $f$ at $x$ if and only if $f'_H(x, v) = L(v)$ for each $v \in X$.

Recall (see, e.g. [17] or [12]), that if $f$ is Hadamard differentiable at $a \in G$, then $f$ is Gâteaux differentiable at $a$, and if $f$ is locally Lipschitz on $G$, then also the opposite implication holds.

Further, if $f$ is Fréchet differentiable at $a \in G$, then $f$ is Hadamard differentiable at $a$, and if $X = \mathbb{R}^n$, then also the opposite implication holds.
A functional $L \in X^*$ (see, e.g., [1]) is said to be a Fréchet subgradient (resp. Hadamard subgradient) of $f$ at $x$, if
\[
\liminf_{h \to 0} \frac{f(x+h) - f(x) - L(h)}{\|h\|} \geq 0 \quad \text{(resp. } L(h) \leq f'_{\text{H}}(x,v), \ v \in X).\]

A functional $L \in X^*$ is said to be a Fréchet supergradient (resp. Hadamard supergradient) of $f$ at $x$, if $-L$ is a Fréchet subgradient (resp. Hadamard subgradient) of $-f$ at $x$.

We say that $f$ is Fréchet (resp. Hadamard) subdifferentiable at $x$ if there exists a Fréchet (resp. Hadamard) subgradient of $f$ at $x$. Fréchet (resp. Hadamard) superdifferentiability is defined analogously. We will need the following well-known facts.

**Fact 2.2.**
(i) If $L \in X^*$ is a Fréchet subgradient of $f$ at $a \in G$, then $L$ is a Hadamard subgradient of $f$ at $a$, and if $X = \mathbb{R}^n$, then also the opposite implication holds.
(ii) $f$ is Fréchet (resp. Hadamard) differentiable at $x$ if and only if $f$ is both Fréchet (resp. Hadamard) subdifferentiable at $x$ and Fréchet (resp. Hadamard) superdifferentiable at $x$.

**Proof.** For (i) see, e.g., [12, p. 266, (4.8) and Proposition 4.6]). For (ii) see, e.g., [12, Remark on p. 266 and Corollary 4.5].

### 2.3. Null sets.

**Definition 2.3.** Let $X$ be a separable Banach space and $B \subset X$ a Borel set.

(i) If $0 \neq v \in X$ and $\varepsilon > 0$, then we say that $B \in \mathcal{A}(v, \varepsilon)$ if \( \{ t : \varphi(t) \in B \} \) is Lebesgue null whenever $\varphi : \mathbb{R} \to X$ is such that the function $x \mapsto \varphi(x) - xv$ has Lipschitz constant at most $\varepsilon$.

(ii) We say that $B \in \mathcal{C}$ if $B$ can be written in the form $B = \bigcup_{n=1}^{\infty} B_n$, where $B_n \in \mathcal{A}(v_n, \varepsilon_n)$ for some $v_n \neq 0$ and $\varepsilon_n > 0$.

We define $\mathcal{C} = \mathcal{C}(X)$ as the system of all $A \subset X$ for which there exists a Borel set $B \in \mathcal{C}$ such that $A \subset B$. The sets from $\mathcal{C}$ will be called $\mathcal{C}$-null.

**Remark 2.4.**
(a) It is easy to see that $\mathcal{C}$ is $\sigma$-ideal.
(b) The present definition of the system $\mathcal{C}$ slightly differs from that of [14], under which each member of $\mathcal{C}$ is Borel. So $\mathcal{C}$ by our definition is the $\sigma$-ideal generated by the corresponding system of [14].
(c) Each member of $\mathcal{C}$ is contained in an Aronszajn null set (see [14, Proposition 13]) and thus it is Haar null. (For definition of Aronszajn and Haar null sets see [2].) Moreover, each member of $\mathcal{C}$ is also $\Gamma$-null (see [20]). The important $\sigma$-ideal of $\Gamma$-null subsets of $X$ was introduced in [8].
(d) The main theorem of [14] works with the system $\mathcal{A}$. We will not need its definition; note only that (obviously) $\widetilde{\mathcal{A}} \subset \mathcal{C}$ and it is not known whether $\widetilde{\mathcal{A}}(X) = \mathcal{C}(X)$ for each $X$.

**Definition 2.5.** Let $X$ be a Banach space.

(i) We say that $A \subset X$ is porous at a point $x \in X$ if there exits a sequence $x_n \to x$ and $c > 0$ such that $B(x_n, c\|x_n - x\|) \cap A = \emptyset$. If, moreover, $(x_n)$ can be taken so that all $x_n$ belong to a half-line $\{ x + tv : t \geq 0 \}$ ($v \neq 0$), we say that $A$ is directionally porous at $x$.

(ii) We say that $A \subset X$ is porous (resp. directionally porous) if $A$ is porous (resp. directionally porous) at each point $x \in A$.

(iii) We say that $A \subset X$ is $\sigma$-porous (resp. $\sigma$-directionally porous) if it is a countable union of porous (resp. directionally porous) sets.
If $X$ is a separable Banach space, then (see, e.g., [19, 3.1])

\[(2.3) \quad \text{each } \sigma\text{-directionally porous subset of } X \text{ belongs to } \tilde{A}, \text{ and so to } \tilde{C}.\]

We will need the following immediate consequence of [7, Theorem 3.1(b)]. It uses the notion of sparse sets (i.e., sets which can be covered by countably many Lipschitz hypersurfaces). We will not need the formal definition of sparse sets, but only the almost obvious fact (see, e.g., [7]), that

\[(2.4) \quad \text{each sparse set is } \sigma\text{-directionally porous.}\]

**Theorem I.** Let $X$ be a separable space, $G \subset X$ an open set and $f : G \to \mathbb{R}$ an arbitrary function. Let $H$ be the set of all $x \in G$, for which $f^H(x, v) + f^H(x, v) > 0$ or $f^H(x, v) + f^H(x, v) < 0$ for some $v \in X$. Then $H$ is sparse.

3. **Lower Lipschitzness via Cone Lower Lipschitzness**

We will need the following easy lemma.

**Lemma 3.1.** Let $X$ be a separable space, $G \subset X$ an open set and $f : G \to \mathbb{R}$ an arbitrary function. Denote by $T(f)$ the set of all $x \in G$ for which there exists a cone $C_x = C(x, v, \delta)$ such that

\[f(x) < \liminf_{y \to x, y \in C_x} f(y).\]

Then $T(f) \in \tilde{C}$.

**Proof.** Let $(r_n)_1^\infty$ be a sequence of all rational numbers. Set

\[T(f, n) := \{x \in T(f) : f(x) < r_n < \liminf_{y \to x, y \in C_x} f(y)\}.\]

Obviously, $T(f) = \bigcup_{n=1}^\infty T(f, n)$. Fix an arbitrary $n \in \mathbb{N}$ and $x \in T(f, n)$. Then there exists $\eta > 0$ such that $f(y) > r_n$ for each $y \in C_x \cap B(x, \eta)$. So $y \notin T(f, n)$ for each $y \in C_x \cap B(x, \eta)$. This clearly implies that $T(f, n)$ is directionally porous and so $T(f)$ is $\sigma$-directionally porous. Thus $T(f) \in \tilde{C}$ by (2.3).

(Note that the above proof shows that $T(f)$ is sparse, but we will not need this stronger fact.)

**Lemma 3.2.** Let $X$ be a separable Banach space, $G \subset X$ an open set, $v \in S_X$, $0 < \delta < 1$ and $f : G \to \mathbb{R}$ an arbitrary function. Denote by $A(f, v, \delta)$ the set of all $x \in G$, for which

(i) $f(y) \geq f(x)$ whenever $y \in C(x, v, \delta) \cap B(x, \delta)$ and

(ii) $\liminf_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} = -\infty$.

Then $A(f, v, \delta) \in \tilde{C}$.

**Proof.** The set $A(f, v, \delta)$ need not be Borel. From this reason we will proceed in two steps. In the first (essential) step we will prove $A(f, v, \delta) \in \tilde{C}$ under the assumption that $A(f, v, \delta)$ is Borel. In the second step we will reduce the general case to the case when $f$ is lower semi-continuous, in which $A(f, v, \delta)$ is Borel.

First step: Suppose that $B := A(f, v, \delta)$ is Borel. It is sufficient to prove that $B \in \tilde{A}(v, \varepsilon)$, where $\varepsilon := \delta/5$. So let $\varphi : \mathbb{R} \to X$ be a mapping such that $\psi : t \to \varphi(t) - tv$ has Lipschitz constant at most $\varepsilon$. Suppose to the contrary that $\lambda(\varphi^{-1}(B)) > 0$. Choose an open interval $I \subset \mathbb{R}$ such that

\[(3.1) \quad \text{diam } I < \frac{\delta}{1 + \varepsilon} \quad \text{and} \quad \lambda(B^*) > 0,\]

where $B^* := \varphi^{-1}(B) \cap I$. 
We will show that the function \( g := f \circ \varphi \big|_{B^*} \) is nondecreasing. So suppose that \( t_1, t_2 \in B^* \) and \( t_1 < t_2 \). Since \( \varphi(t_2) - \varphi(t_1) = (t_2 - t_1)v + (\psi(t_2) - \psi(t_1)) \), using (2.1) with \( u := (t_2 - t_1)v \) and \( w := \varphi(t_2) - \varphi(t_1) \), we obtain

\[
\left\| v - \frac{\varphi(t_2) - \varphi(t_1)}{\|\varphi(t_2) - \varphi(t_1)\|} \right\| \leq \frac{2}{|t_2 - t_1|} \|\psi(t_2) - \psi(t_1)\| \leq 2\varepsilon < \frac{\delta}{2}.
\]

So \( \varphi(t_2) \in C(\varphi(t_1), v, \delta/2) \). Further, using (3.1), we obtain

\[
(1 - \varepsilon)(t_2 - t_1) \leq \|\varphi(t_2) - \varphi(t_1)\| \leq (1 + \varepsilon)(t_2 - t_1) < \delta.
\]

So we obtain

\[
\varphi(t_2) \in C(\varphi(t_1), v, \delta/2) \cap B(\varphi(t_1), \delta).
\]

Since \( \varphi(t_1) \in B \), by (i) we obtain \( f(\varphi(t_2)) \geq f(\varphi(t_1)) \). So \( g \) is nondecreasing.

Set \( J := (\inf B^*, \sup B^*) \) and \( \tilde{g}(t) := \sup\{g(\tau) : \tau \in B^* \cap (-\infty, t]\} \) for \( t \in J \). Then \( \tilde{g} \) extends \( g \) and is finite and nondecreasing on \( J \). Consequently we can choose \( t_0 \in B^* \cap J \) such that

\[
(\tilde{g})'(t_0) \in \mathbb{R} \quad \text{and} \quad t_0 \quad \text{is a density point of} \quad B^*.
\]

Consequently for \( K := (\tilde{g})'(t_0) + 1 \) there exists \( 0 < \alpha < \varepsilon \) such that for each \( 0 < h < \alpha \) there exists a number \( t \in (t_0 - h - \varepsilon h, t_0 - h) \cap B^* \) such that

\[
|f(\varphi(t)) - f(\varphi(t_0))| \leq K|t - t_0|.
\]

Set \( x_0 := \varphi(t_0) \) and \( L := 6K(1 + \varepsilon)^{-1} \).

Since \( \varphi(t_0) \in B \), by (ii) we can find \( y \in X \) such that

\[
h := 6\varepsilon^{-1}\|y - x_0\| < \alpha \quad \text{and} \quad \frac{f(y) - f(x_0)}{\|y - x_0\|} < -L.
\]

Since \( 0 < h < \alpha \), we can choose \( t \in (t_0 - h - \varepsilon h, t_0 - h) \cap B^* \) such that (3.5) holds.

Since \( t, t_0 \in B^* \), we can use (3.2) and (3.3) (with \( t_1 := t \) and \( t_2 := t_0 \)) and obtain

\[
(1 - \varepsilon)h \leq \|x_0 - \varphi(t)\| \leq (1 + \varepsilon)^2 h
\]

and

\[
\left\| \frac{x_0 - \varphi(t)}{\|x_0 - \varphi(t)\|} - v \right\| < \frac{\delta}{2}.
\]

Using (2.1), (3.7) and \( \varepsilon < 1/3 \), we obtain

\[
\left\| \frac{x_0 - \varphi(t)}{\|x_0 - \varphi(t)\|} - \frac{y - \varphi(t)}{\|y - \varphi(t)\|} \right\| \leq 2 \left\| \frac{y - x_0}{\|x_0 - \varphi(t)\|} \right\| \leq \frac{2\|y - x_0\|}{(1 - \varepsilon)6\varepsilon^{-1}\|y - x_0\|} = \frac{\delta}{3(1 - \varepsilon)} < \frac{\delta}{2}.
\]

Consequently (3.8) implies

\[
\left\| \frac{y - \varphi(t)}{\|y - \varphi(t)\|} - v \right\| < \delta.
\]

Further (3.6) and (3.7) imply

\[
\|y - \varphi(t)\| \leq \|x_0 - \varphi(t)\| + h < 5h < 5\varepsilon = \delta.
\]

Thus \( y \in C(\varphi(t), v, \delta) \cap B(\varphi(t), \delta) \), and since \( \varphi(t) \in B \), we obtain by (i) that \( f(y) \geq f(\varphi(t)) \). Consequently, using (3.6), we obtain

\[
f(x_0) - f(\varphi(t)) = (f(x_0) - f(y)) + (f(y) - f(\varphi(t))) \geq f(x_0) - f(y) > L\|y - x_0\|.
\]

On the other hand, (3.5) gives

\[
f(x_0) - f(\varphi(t)) \leq K|t - t_0| < K(1 + \varepsilon)h = K(1 + \varepsilon)6\varepsilon^{-1}\|y - x_0\| = L\|y - x_0\|,
\]

a contradiction.

Second step: Now consider the general case. First observe that we can suppose that \( f \) is bounded. Indeed, setting \( f_n := \max(-n, \min(f, n)) \) for \( n \in \mathbb{N} \), it is easy to see that \( A(f, v, \delta) \subset \bigcup_{n=1}^{\infty} A(f_n, v, \delta) \).
Set
\[ g(x) := \min(f(x), \liminf_{t \to x} f(t)). \]
Obviously, \( g \) is a bounded lower semi-continuous function. The definitions of \( A(f, v, \delta) \) and \( g \) clearly imply that
\[
\text{(3.9)} \quad A(f, v, \delta) \subset A(g, v, \delta) \cup \{ x \in A(f, v, \delta) : f(x) > g(x) \}.
\]
Now we will show that \( A(g, v, \delta) \) is a Borel set. To this end first consider the set
\[
M := \{ x \in X : g(y) \geq g(x) \text{ whenever } y \in C(x, v, \delta) \cap B(x, \delta) \}.
\]
We will show that \( M \) is closed. To this end consider points \( x_n \in M, n \in \mathbb{N} \), such that \( x_n \to x \).
Let \( y \in C(x, v, \delta) \cap B(x, \delta) \). It is easy to see that there exists \( n_0 \) such that, for all \( n \geq n_0 \), we have \( y \in C(x_n, v, \delta) \cap B(x_n, \delta) \), and consequently \( g(x_n) \leq g(y) \). Since \( g \) is lower-semicontinuous, we obtain \( g(x) \leq g(y) \). So \( x \in M \).
Further denote
\[
L := \{ x \in X : \liminf_{y \to x} \frac{g(y) - g(x)}{\|y - x\|} > -\infty \}
\]
and
\[
L_n := \{ x \in X : g(y) - g(x) \geq -n \|y - x\| \text{ if } \|y - x\| < 1/n \}, \quad n \in \mathbb{N}.
\]
Then clearly \( L = \bigcup_{n=1}^{\infty} L_n \). We will show that each \( L_n \) is closed. To this end consider points \( x_k \in L_n, k \in \mathbb{N} \), such that \( x_k \to x \). Let \( y \in B(x, 1/n) \). It is easy to see that there exists \( k_0 \) such that, for all \( k \geq k_0 \), we have \( \|y - x_k\| < 1/n \), and consequently \( g(y) - g(x_k) \geq -n \|y - x_k\| \).
Consequently
\[
g(y) - g(x) \geq g(y) - \liminf_{k \to \infty} g(x_k) = \limsup_{k \to \infty} (g(y) - g(x_k)) \geq \limsup_{k \to \infty} (-n \|y - x_k\|) = -n \|y - x\|,
\]
and so \( x \in L_n \).
Thus we obtain that \( A(g, v, \delta) = M \setminus L \) is Borel. Using the first step of the proof, we obtain \( A(g, v, \delta) \in \mathcal{C} \).
Further consider \( x \in A(f, v, \delta) \) such that \( f(x) > g(x) \). Since \( f(y) \geq f(x) \) for each \( y \in C(x, v, \delta) \cap B(x, \delta) \), we clearly have \( g(y) \geq f(x) \) for each \( y \in C(x, v, \delta) \cap B(x, \delta) \). So \( x \in T(g) \), where \( T(g) \) is as in Lemma 3.1. Therefore \( \{ x \in A(f, v, \delta) : f(x) > g(x) \} \subset T(g) \). So, using Lemma 3.1 and (3.9), we obtain \( A(f, v, \delta) \in \mathcal{C} \).

**Lemma 3.3.** Let \( X \) be a separable Banach space, \( G \subset X \) an open set, \( v \in S_X \), \( 0 < \delta < 1 \), \( K > 0 \) and \( f : G \to \mathbb{R} \) an arbitrary function. Let \( M(f, v, \delta, K) \) be the set of all \( x \in G \), for which
\[
\begin{align*}
(i) \quad f(y) - f(x) &\geq -K \|y - x\| \text{ whenever } y \in C(x, v, \delta) \cap B(x, \delta) \text{ and} \\
(ii) \quad \liminf_{z \to x} f(z) - f(x) \|z - x\| &= -\infty.
\end{align*}
\]
Then \( M(f, v, \delta, K) \in \mathcal{C} \).

**Proof.** Choose \( x^* \in X^* \) with \( x^*(v) > 2K \) and set \( g := f + x^* \), \( \tilde{\delta} := \min(\delta, K \|x^*\|^{-1}) \). We will show that \( M(f, v, \delta, K) \subset A(g, v, \tilde{\delta}) \), where \( A(g, v, \tilde{\delta}) \) is as in Lemma 3.2. To this end choose an arbitrary \( x \in M(f, v, \delta, K) \) and \( y \in C(x, v, \tilde{\delta}) \cap B(x, \tilde{\delta}) \). Since \( \tilde{\delta} \leq \delta \), we have
\[
\text{(3.10)} \quad f(y) - f(x) \geq -K \|y - x\|.
\]
We have \( \|v - (y - x)\|/\|y - x\|^{-1} \| < \tilde{\delta} \), and therefore
\[
\left| x^*(v) - \frac{x^*(y) - x^*(x)}{\|y - x\|} \right| < \tilde{\delta}\|x^*\| \leq K.
\]
Consequently
\[
\text{(3.11)} \quad x^*(y) - x^*(x) \geq x^*(v)\|y - x\| - K\|y - x\| > K\|y - x\|.
\]
Adding (3.10) and (3.11), we obtain \( g(y) \geq g(x) \). Since clearly \( \liminf_{z \to x} \frac{g(z) - g(x)}{\|z - x\|} = -\infty \), we obtain \( x \in A(g, v, \tilde{\delta}) \). Thus Lemma 3.2 implies \( M(f, v, \delta, K) \in \tilde{C} \).

**Lemma 3.4.** Let \( X \) be a separable Banach space, \( G \subset X \) an open set and \( f : G \to \mathbb{R} \) an arbitrary function. Let \( P_1 \) be the set of all \( x \in G \), for which

\[
\begin{align*}
&\text{(i)} \quad f_H^-(x, v) > -\infty \text{ for some } v \in X \\
&\text{(ii)} \quad \liminf_{z \to x} f(z) - f(x) = -\infty.
\end{align*}
\]

Then \( P_1 \subset \tilde{C} \).

**Proof.** Let \( \{v_n : n \in \mathbb{N}\} \) be a dense subset of \( S_X \). By Lemma 3.3 it is sufficient to show (under the notation of Lemma 3.3) that

\[
(3.12) \quad P_1 \subset \bigcup_{n, m, k=1}^{\infty} M(f, v_n, 1/m, k).
\]

To prove (3.12), consider an arbitrary \( x \in P \). Choose \( v \in X \) such that \( f_H^-(x, v) > -\infty \). By (2.2) and Lemma 2.1 we can (and will) suppose that \( v \in S_X \). Choose \( k \in \mathbb{N} \) such that \( f_H^-(x, v) > -k \).

We can clearly find \( \delta > 0 \) such that \( f(y) - f(x) > -k\|y - x\| \) for each \( y \in C(x, v, \delta) \cap B(x, \delta) \). Further choose \( n \in \mathbb{N} \) such that \( \|v_n - v\| < \delta \) and \( m \in \mathbb{N} \) such that \( \|v_n - v\| + 1/m < \delta \). It is easy to see that \( x \in M(f, v_n, 1/m, k) \).

Applying Lemma 3.4 to \(-f\), we obtain

**Corollary 3.5.** Let \( X \) be a separable Banach space, \( G \subset X \) an open set and \( f : G \to \mathbb{R} \) an arbitrary function. Let \( P_2 \) be the set of all \( x \in G \), for which

\[
\begin{align*}
&\text{(i)} \quad f_H^+(x, v) < \infty \text{ for some } v \in S_X \\
&\text{(ii)} \quad \limsup_{z \to x} f(z) - f(x) = \infty.
\end{align*}
\]

Then \( P_2 \subset \tilde{C} \).

4. **Subdifferentiability via lower Lipschitzness**

**Proposition 4.1.** Let \( X \) be a separable Banach space and \( \mathcal{I} \) a \( \sigma \)-ideal of subsets of \( X \). Suppose that

\(\text{(R)}\quad \text{Every real Lipschitz function on each open } \emptyset \neq H \subset X \text{ is Fréchet (resp. Hadamard) differentiable on } H \text{ except for a set from } \mathcal{I}.\)

Let \( G \subset X \) be an open set, \( f \) an arbitrary real function on \( G \). Let \( A \) be the set of all \( x \in G \) such that \( \liminf_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} > -\infty \) and \( f \) is not Fréchet (resp. Hadamard) subdifferentiable at \( x \). Then \( A \in \mathcal{I} \).

**Proof.** For each \( n \in \mathbb{N} \), set

\[
L_n := \{x \in G : f(y) - f(x) \geq -n\|y - x\| \text{ whenever } \|y - x\| \leq 1/n\}.
\]

Let \( (U^n_k)_{k \in \mathbb{N}} \) be a cover of \( X \) with open sets with diameter smaller than \( 1/n \) and set \( A^n_k := A \cap L_n \cap U^n_k \). Since clearly \( A = \bigcup_{n,k=1}^{\infty} A^n_k \), it is sufficient to prove that each \( A^n_k \) belongs to \( \mathcal{I} \).

So suppose that natural \( n, k \) with \( A^n_k \neq \emptyset \) are fixed. Set

\[
h_{n,k}(x) := \sup\{h(x) : h \text{ is Lipschitz with constant } n \text{ on } U^n_k \text{ and } h \leq f \text{ on } U^n_k\}.
\]

Consider, for \( a \in A^n_k \), the function

\[
h_a(x) := f(a) - n\|x - a\|, \quad x \in U^n_k.
\]

Clearly each \( h_a \) is Lipschitz with constant \( n \) and, since \( A^n_k \subset L_n \) and \( \text{diam} U^n_k < 1/n \), we have \( h_a \leq f \) on \( U^n_k \). Consequently we obtain that \( h_{n,k} \) is finite and Lipschitz with constant \( n \) on \( U^n_k \);

\[
(4.1) \quad h_{n,k} \leq f \text{ on } U^n_k \text{ and } h_{n,k}(a) = f(a) \text{ for each } a \in A^n_k.
\]
By (R) there exists $N^n_k \in \mathcal{I}$ such that $h_{n,k}$ is Fréchet (resp. Hadamard) differentiable at each point of $U^n_k \setminus N^n_k$. Using (4.1), we easily obtain (see, e.g., [12, Proposition 4.7]) that $f$ is Fréchet (resp. Hadamard) subdifferentiable at each point of $A^n_k \setminus N^n_k$. Therefore $(A^n_k \setminus N^n_k) \cap A^n_k = \emptyset$. Consequently $A^n_k \subseteq N^n_k$, and so $A^n_k \in \mathcal{I}$.

**Corollary 4.2.** Let $X$ be a Banach space such that

(a) $X^*$ is separable, and
(b) each porous subset of $X$ is $\Gamma$-null.

Let $G \subseteq X$ be an open set and $f$ an arbitrary real function on $G$. Let $S_1$ be the set of all $x \in G$ such that either

(i) $\lim \inf_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} > -\infty$ and $f$ is not Fréchet subdifferentiable at $x$ or
(ii) $\lim \sup_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} < \infty$ and $f$ is not Fréchet superdifferentiable at $x$.

Then $S_1$ is a $\Gamma$-null set.

**Proof.** Let $\mathcal{I}$ be the $\sigma$-ideal of $\Gamma$-null sets in $X$. Then the condition (R) of Proposition 4.1 for Fréchet differentiability holds (see [8] or [9]). Applying Proposition 4.1 to $f$ and $-f$, we obtain $\Gamma$-null sets $A_1$ and $A_2$, respectively. So $S_1 = A_1 \cup A_2$ is $\Gamma$-null.

**Corollary 4.3.** Let $X$ be a separable Banach space. Let $G \subseteq X$ be an open set and $f$ an arbitrary real function on $G$. Let $S_2$ be the set of all $x \in G$ such that either

(i) $\lim \inf_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} > -\infty$ and $f$ is not Hadamard subdifferentiable at $x$ or
(ii) $\lim \sup_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} < \infty$ and $f$ is not Hadamard superdifferentiable at $x$.

Then $S_2 \subseteq \hat{C}$.

**Proof.** Let $\mathcal{I} := \hat{C}$. Then [14, Theorem 12 and Proposition 13] imply that the condition (R) of Proposition 4.1 for Gâteaux differentiability holds. However, since (R) deals with Lipschitz functions, it holds for Hadamard differentiability as well (see, e.g., [12, Proposition 2.25]). Applying Proposition 4.1 to $f$ and $-f$, we obtain sets $A_1 \in \hat{C}$ and $A_2 \in \hat{C}$, respectively. So $S_2 = A_1 \cup A_2 \in \hat{C}$.

5. **Main results**

**Theorem 5.1.** Let $X$ be a Banach space such that

(a) $X^*$ is separable, and
(b) each porous subset of $X$ is $\Gamma$-null.

Let $G \subseteq X$ be an open set and $f$ an arbitrary real function on $G$. Then there exists a $\Gamma$-null set $A \subseteq G$ such that, for each $x \in G \setminus A$, one from the following assertions holds:

(i) $f$ is Fréchet differentiable at $x$.
(ii) $f^+_H(x, v) = \infty$ for each $v \in X$ and $f^-_H(x, v) = -\infty$ for each $v \in X$.
(iii) $f^+_H(x, v) = \infty$ for each $v \in X$, $L(v) := f^-_H(x, v) \in X^*$ and $L$ is a Fréchet subgradient of $f$ at $x$.
(iv) $f^+_H(x, v) = -\infty$ for each $v \in X$, $L(v) := f^-_H(x, v) \in X^*$ and $L$ is a Fréchet supergradient of $f$ at $x$.

**Proof.** Let $H$ be the set from Theorem I (at the end of Preliminaries), $S_1$ the set from Corollary 4.2 and $P_1, P_2$ the sets from Lemma 3.4 and Corollary 3.5. Set $A := H \cup S_1 \cup P_1 \cup P_2$. Then $A$ is $\Gamma$-null by (2.4), (2.3) and Remark 2.4(c). Let $x \in G \setminus A$ be given. Consider the conditions

(C1) $f^+_H(x, v) = \infty$, $v \in X$, and (C2) $f^-_H(x, v) = -\infty$, $v \in X$.

There are four possibilities.
(i)* Neither (C1) nor (C2) hold. Since \( x \notin P_1 \cup P_2 \), we have that
\[
\liminf_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} > -\infty \quad \text{and} \quad \limsup_{z \to x} \frac{f(z) - f(x)}{\|z - x\|} < \infty.
\]
So, since \( x \notin S_1 \), we obtain that \( f \) is both Fréchet subdifferentiable at \( x \) and Fréchet superdifferentiable at \( x \). So (i) holds by Fact 2.2(ii).

(ii)* Both (C1) and (C2) hold. In other words, (ii) holds.

(iii)* (C1) holds and (C2) does not hold. Since \( x \notin P_1 \cup S_1 \), we obtain as in the case (i)* that \( f \) is Fréchet subdifferentiable at \( x \). Let \( L \) be a Fréchet subgradient of \( f \) at \( x \). Fact 2.2(i) implies that \( f^+_H(x, v) \geq L(v) \) for each \( v \in X \). To prove that \( f^-_H(x, v) = L(v) \) for each \( v \in X \), suppose to the contrary that \( f^-_H(x, v) > L(v) \) for some \( v \in X \). Then
\[
f^-_H(x, v) + f^-_H(x, -v) > L(v) + L(-v) = 0,
\]
which contradicts \( x \notin H \). So (iii) holds.

(iv)* (C2) holds and (C1) does not hold. Then, quite analogously as in the case (iii)*, we obtain that (iv) holds. \( \square \)

Remark 5.2. The assumptions (a) and (b) are satisfied (see [8] or [9]) if
(i) \( X \) is a subspace of \( c_0 \), or
(ii) \( X = C(K) \), where \( K \) is a separable compact space, or
(iii) \( X \) is the Tsirelson space.

Theorem 5.3. Let \( X \) be a separable Banach space. Let \( G \subset X \) be an open set and \( f \) an arbitrary real function on \( G \). Then there exists a set \( A \in \mathcal{C} \) such that, for each \( x \in G \setminus A \), one from the following assertions holds:

(i) \( f \) is Hadamard differentiable at \( x \).
(ii) \( f^+_H(x, v) = \infty \) for each \( v \in X \) and \( f^-_H(x, v) = -\infty \) for each \( v \in X \).
(iii) \( f^+_H(x, v) = \infty \) for each \( v \in X \) and \( L(v) := f^-_H(x, v) \in X^* \).
(iv) \( f^-_H(x, v) = -\infty \) for each \( v \in X \) and \( L(v) := f^+_H(x, v) \in X^* \).

Proof. We obtain the proof, if we replace in the proof of Theorem 5.1:

(i) “Fréchet” by “Hadamard”,
(ii) “\( \Gamma \)-null” by \( \tilde{C} \)-null” and
(iii) “\( S_1 \)” by “\( S_2 \)” (where \( S_2 \) is the set from Corollary 4.3).

(Of course, now we do not use Remark 2.4(c) and Fact 2.2(i).) \( \square \)

Now we state explicitly generalizations of Stepanov theorem, which immediately follow from the above theorems.

Corollary 5.4. Let \( X \), \( G \) and \( f \) be as in Theorem 5.1. Let \( \hat{S}(f) \) be the set of all \( x \in G \), for which there exist \( v_1, v_2 \in S_X \) and \( \delta_1 > 0 \), \( \delta_2 > 0 \) such that
\[
\limsup_{y \to x, y \in S_X(v_1, \delta_1)} \frac{f(y) - f(x)}{\|y - x\|} < \infty \quad \text{and} \quad \liminf_{y \to x, y \in S_X(v_2, \delta_2)} \frac{f(y) - f(x)}{\|y - x\|} > -\infty.
\]
Then there exists a \( \hat{\Gamma} \)-null set \( N \subset X \) such that \( f \) is Fréchet differentiable at all points of \( \hat{S}(f) \setminus N \).

Corollary 5.5. Let \( X \), \( G \) and \( f \) be as in Theorem 5.3. Let \( \hat{S}(f) \) be the set of all \( x \in G \), for which there exist \( v_1, v_2 \in S_X \) and \( \delta_1 > 0 \), \( \delta_2 > 0 \) such that
\[
\limsup_{y \to x, y \in S_X(v_1, \delta_1)} \frac{f(y) - f(x)}{\|y - x\|} < \infty \quad \text{and} \quad \liminf_{y \to x, y \in S_X(v_2, \delta_2)} \frac{f(y) - f(x)}{\|y - x\|} > -\infty.
\]
Then there exists a set \( N \in \tilde{C}(X) \) such that \( f \) is Hadamard differentiable at all points of \( \hat{S}(f) \setminus N \).
Remark 5.6. For $X = \mathbb{R}^2$, Corollary 5.4 was first proved by S. Saks in [15, Th. 7, p. 238]. The “basic version of the Denjoy-Young-Saks theorem” of [13] easily implies a weaker version (in which $v_2 = -v_1$) of Corollary 5.5.

Remark 5.7. The following easy examples show that Theorem 5.3 gives the strongest relation among Hadamard directional derivatives $f^+_H(x,v)$, $f^-_H(x,v)$ ($v \in X)$ which holds a.e. for an arbitrary function on $X$. Here “a.e.” can be taken in the sense of $\tilde{C}$-null sets, Aronszajn null sets, Haar null sets or $\Gamma$-null sets. The above statement has an obvious precise meaning, but we omit its formal (rather lengthy) formulation.

Let $X$ be a separable Banach space, $L \in X^*$ and $C$, $D$ two disjoint countable sets dense in $X$.

(i) If $f := L$, then $f^+_H(x) = L$ for each $x \in X$.

(ii) If $f := \chi_C - \chi_D$, then $f^+_H(x,v) = \infty$ and $f^-_H(x,v) = -\infty$ for each $x \in X \setminus (C \cup D)$ and $v \in X$ (and the set $X \setminus (C \cup D)$ is not null in any sense mentioned above).

(iii) If $f := L + \chi_C$, then $f^+_H(x,v) = \infty$ and $L(v) = f^-_H(x,v)$ for each $x \in X \setminus C$ and $v \in X$.

(iv) If $f := L - \chi_C$, then $f^+_H(x,v) = -\infty$ and $L(v) = f^-_H(x,v)$ for each $x \in X \setminus C$ and $v \in X$.
