Abstract. We present a model of the gravitational field based on two symmetric tensors. The equations of motion of test particles are derived: Massive particles do not follow a geodesic but massless particles trajectories are null geodesics of an effective metric. Outside matter, the predictions of the model coincide exactly with General Relativity, so all classical tests are satisfied. In Cosmology, we get accelerated expansion without a cosmological constant.

1. Introduction

General Relativity (GR) works very well at the macroscopic scales[1]. Its quantization has proved to be difficult, though. It is non-renormalizable, which prevents its unification with the other forces of Nature. Trying to make sense of Quantum GR is the main physical motivation of String Theories [2]. Moreover, recent discoveries in Cosmology [3, 4] has revealed that most part of matter is in the form of unknown matter (dark matter, DM) and that the dynamics of the expansion of the Universe is governed by a mysterious component that accelerates the later stages of the expansion (dark energy, DE). Although GR is able to accommodate both DM and DE, the interpretation of the dark sector in terms of fundamental theories of elementary particles is problematic[5]. Although some candidates exists that could play the role of DM, none have been detected yet. Also, an alternative explanation based on the modification of the dynamics for small accelerations cannot be ruled out[6].

In GR, DE can be explained if a small cosmological constant (Λ) is present. At the later stages of the evolution of the Universe Λ will dominate the expansion, explaining the acceleration. Such small Λ is very difficult to generate in Quantum Field Theory (QFT) models, because in this models Λ is the vacuum energy, which is usually very large.

In recent years there has been various proposals to explain the observed acceleration of the universe. They involve the inclusion of some additional field like in quintessence, chameleon, vector dark energy or massive gravity; Addition of higher order terms in the Einstein-Hilbert action, like f(R) theories and Gauss-Bonnet terms; Modification of gravity on large scales by introduction of extra dimensions. For a review, see [7].

Less widely explored, but interesting possibilities, are the search for non-trivial ultraviolet fixed points in gravity (asymptotic safety[9]) and the notion of induced gravity[10]. The first possibility uses exact renormalization-group techniques[11] and lattice and numerical techniques such as Lorentzian triangulation analysis[12]. Induced gravity proposed that gravitation is a residual force produced by other interactions.
In a recent paper, [13] a two-dimensional field theory model explored the emergence of geometry by the spontaneous symmetry breaking of a larger symmetry where the metric is absent. Previous work in this direction can be found in [14], [15] and [16].

In this paper, we will review the results of [17]. The main observation is that GR is finite on shell at one loop [18]. In [20, 19] we presented a type of gauge theories, $\delta$ gauge theories (DGT): The main properties of DGT are: 1) The classical equations of motion are satisfied in the full Quantum theory 2) They live at one loop. 3) They are obtained through the extension of the former symmetry of the model introducing an extra symmetry that we call $\delta$ symmetry, since it is formally obtained as the variation of the original symmetry. When we apply this prescription to GR we obtain $\delta$ gravity. Quantization of $\delta$ gravity is discussed in [21].

The impact of dark energy on cosmological observations can be expressed in terms of a fluid equation of state $p = w(R)\rho$, which is to be determined studying its influence on the large-scale structure and dynamics of the Universe.

In this paper we follow the same approach. So we will not include the matter dynamics, except by demanding that the energy-momentum tensor of the matter fluid is covariantly conserved. This is required in order to respect the symmetries of the model.

The main properties of this model at the classical level are: a) It agrees with GR, outside the sources and with adequate boundary conditions. In particular, the causal structure of delta gravity in vacuum is the same as in General Relativity. So all standard tests are satisfied automatically. b) When we study the evolution of the Universe, it predicts acceleration without a cosmological constant or additional scalar fields. The Universe ends in a Big Rip, similar to the scenario considered in [23]. c) The scale factor agrees with the standard cosmology at early times and show acceleration only at late times. Therefore we expect that density perturbations should not have large corrections.

It should be remarked that $\delta$ gravity is not a metric model of gravity because massive particles do not move on geodesics. Only massless particles move on null geodesics of a linear combination of both tensor fields.

It was noticed in [20] that the Hamiltonian of delta models is not bounded from below. Phantoms cosmological models [22], [23] also have this property. Although it is not clear whether this problem will subsist in a diffeomorphism invariant model as delta gravity or not, we mention some ways out of the difficulty at the end.

In chapter 2, we write the action defining the model and the corresponding symmetries. Section 3 discusses the motion of particles in the model. In section 4 we define proper time and distances. In section 5, we obtain the Newtonian limit. In section 6 we solve the equations of the model for Friedman-Robertson-Walker metric. In section 7, we find the red shift. In section 8, we define luminosity distance. In section 9, we fit the equations of section 6 to the Supernova Ia data. Section 10 contains the conclusions and brief discussions of open problems. In Appendix A, we review $\delta$-symmetries. In Appendix B we discuss a simpler model: A delta harmonic oscillator, to illustrate the boundedness of the Hamiltonian.

2. Definition of Delta gravity

In this section we define the action as well as the symmetries of the model and derive the equations of motion.
We use the metric convention of [8]. The action of \( \delta \) gravity is:

\[
S(g, \tilde{g}, \lambda) = \int d^dx \sqrt{-g} \left( -\frac{1}{2\kappa} R + \mathcal{L}_M \right) + 
\]

\[
\kappa^2 \int \left[ \left( R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R \right) \right] \sqrt{-\tilde{g}} \tilde{g}^{\mu\nu} d^dx + 
\]

\[
\kappa^2 \int \sqrt{-g} \left( \lambda^{\mu\nu} + \lambda^{\nu\mu} \right) T_{\mu\nu} d^dx 
\]

(1)

Here \( \kappa = \frac{8\pi G}{c^4} \), \( \kappa_2 \) is an arbitrary constant and \( T_{\mu\nu} := -\frac{2}{\sqrt{-g}} \frac{\delta(\sqrt{-g} \mathcal{L}_M)}{\delta g^{\mu\nu}} \) is the energy-momentum tensor of matter. \( R_{\mu\nu} \) is the Ricci’s tensor and \( R \) is the curvature scalar of \( g_{\mu\nu} \). \( \tilde{g}^{\mu\nu} \) is a two-contravariant tensor under general coordinate transformations.

The action (1) is obtained by applying the prescription contained in [20, 19]. That is, we add to the action of general relativity, the variation of it and consider the variation \( \delta g_{\mu\nu} = g_{\mu\nu} \) as a new field. Similarly, the symmetries we write below are obtained as variation of the infinitesimal general coordinate transformations where the variation of the infinitesimal parameter \( \delta \xi^\rho = \xi_1^\rho \) is the infinitesimal parameter of the new transformation \( \delta \). The last term in (1) is needed to implement the condition \( T_{\mu\nu}^{(2)} = 0 \) as an equation of motion in order to implement the \( \delta \) symmetry (2) off shell. This term is not needed in vacuum.

Action (1) is invariant under the following transformations(\( \delta \)):

\[
\delta g_{\mu\nu} = g_{\mu\rho} \xi_0^{\rho\nu} + g_{\nu\rho} \xi_0^{\rho\mu} + g_{\mu\nu,\rho} \xi_0^\rho = \xi_{0\mu\nu} + \xi_{0\nu\mu} \\
\delta \tilde{g}_{\mu\nu}(x) = \xi_{1\mu\nu} + \xi_{1\nu\mu} + \tilde{g}_{0\mu\nu,\rho} + \tilde{g}_{0\nu\mu,\rho} + \tilde{g}_{\mu\nu,\rho} \xi_0^\rho \\
\delta \lambda_{\mu} = -\xi_{1\mu} + \lambda_{\rho} \xi_0^{\rho\mu} + \lambda_{\mu} \xi_0^\rho 
\]

(2)

From now on we will fix the gauge \( \lambda_{\mu} = 0 \). This gauge preserves general coordinate transformations but fixes completely the extra symmetry with parameter \( \xi_{1\mu} \).

Equations of motion Varying \( g_{\mu\nu} \) we get:

\[
S^{\gamma\sigma} + \frac{1}{2} \left( R g^{\gamma\sigma} - g_{\mu\nu} \tilde{g}^{\mu\nu} R^{\gamma\sigma} \right) - \frac{1}{2} g^{\gamma\sigma} \frac{1}{\sqrt{-g}} \left( \sqrt{-g} \nabla_{\nu} \tilde{g}^{\mu\nu} \right)_{,\mu} + \\
\frac{1}{4} g^{\gamma\sigma} \frac{1}{\sqrt{-g}} \left( \sqrt{-g} g^{\alpha\beta} \nabla_{\alpha} \left( g_{\mu\nu} \tilde{g}^{\mu\nu} \right) \right)_{,\alpha} = \kappa \frac{\delta T_{\mu\nu}}{\delta g^{\mu\nu}} \tilde{g}_{\mu\nu} 
\]

(3)

where \( S^{\gamma\sigma} = (U^{\alpha\beta\gamma\rho} + U^{\gamma\beta\alpha\rho} - U^{\sigma\gamma\beta\rho})_{,\rho} \beta \), \( U^{\alpha\beta\gamma\rho} = \frac{1}{2} \left[ g^{\rho\sigma} \tilde{g}^{\beta\alpha} - \frac{1}{2} g^{\alpha\beta} g_{\mu\nu} \tilde{g}^{\mu\nu} \right] \).

Varying \( \tilde{g}^{\mu\nu} \) we get Einstein equation:

\[
\left( R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R \right) + \kappa T_{\mu\nu} = 0 
\]

(4)

Varying \( \lambda_{\mu} \) we get:\( T_{\mu\nu}^{(2)} = 0 \)

Covariant derivatives as well as raising and lowering of indices are defined using \( g_{\mu\nu} \). Notice that outside the sources(\( T_{\mu\nu} = 0 \)), a solution of (3) is \( \tilde{g}^{\mu\nu} = \lambda g^{\mu\nu} \), for a constant \( \lambda \), since \( g_{\rho\mu}^{\alpha\beta} = 0 \) and \( R_{\mu\nu} = 0 \). We will have \( \tilde{g}^{\mu\nu} = g^{\mu\nu} \), assuming that both fields satisfy the same boundary conditions far from the sources.

The equation for \( \tilde{g}^{\mu\nu} \) is linear and of second order in the derivatives.
3. Particle motion in the gravitational field

We are aware of the presence of the gravitational field through its effects on test particles. For this reason, here we discuss the coupling of a test particle to a background gravitational field, such that the action of the particle is invariant under (2).

In $\delta$ gravity we postulate the following action for a test particle:

$$S_p = -m \int dt \sqrt{-g_{\mu\nu} \dot{x}^\mu \dot{x}^\nu + \kappa_2' \int d^3 y \sqrt{-g} T_{\mu\nu} (\tilde{g}^{\mu\nu} + \lambda^{\mu\nu} + \lambda^{\nu\mu})}$$

where $T_{\mu\nu}$ is the energy momentum tensor of the test particle:

$$T_{\mu\nu}(y) = \frac{m}{2\sqrt{-g}} \int dt \frac{\dot{x}_\mu \dot{x}_\nu}{\sqrt{-g_{\alpha\beta} \dot{x}^\alpha \dot{x}^\beta}} \delta(y - x)$$

$\kappa_2' = \kappa_2 \kappa$ is a dimensionless constant.

That is:

$$S_p = m \int \frac{dt}{\sqrt{-g_{\alpha\beta} \dot{x}^\alpha \dot{x}^\beta}} \left( g_{\mu\nu} + \frac{\kappa_2'}{2} \tilde{g}_{\mu\nu} \right) \dot{x}^\mu \dot{x}^\nu$$

(5)

were $\tilde{g}_{\mu\nu} = \tilde{g}_{\mu\nu} + \lambda^{\mu\nu} + \lambda^{\nu\mu}$. Notice that $S_p$ is invariant under (2) and $t$-parametrizations.

From now on we work in the gauge $\lambda_{\mu} = 0$.

Since far from the sources, we must have free particles in Minkowski space, i.e $g_{\mu\nu} \sim \eta_{\mu\nu}, \tilde{g}_{\mu\nu} \sim \eta_{\mu\nu}$, it follows that we are describing the motion of a particle of mass $m' = m(1 + \kappa_2')$.

Since in vacuum $\tilde{g}^{\mu\nu} = g^{\mu\nu}$, the equation of motion for test particles is the same as Einstein’s.

Moreover, the equation of motion is independent of the mass of the particle.

In order to include massless particles, we prefer to use the action [24]:

$$L = \frac{1}{2} \int dt \left( vm^2 - v^{-1} (g_{\mu\nu} + \kappa_2' \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu + \frac{m^2 + v^{-2} (g_{\mu\nu} + \kappa_2' \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu}{2v^{-2}g_{\alpha\beta} \dot{x}^\alpha \dot{x}^\beta} \left(m^2 + v^{-2} g_{\lambda\rho} \dot{x}^\lambda \dot{x}^\rho\right) \right)$$

(6)

This action is invariant under reparametrizations:

$$x'(t') = x(t); dt' v'(t') = dt v(t); t' = t - \epsilon(t)$$

(7)

The equation of motion for $v$ is:

$$v = - \frac{\sqrt{-g_{\mu\nu} \dot{x}^\mu \dot{x}^\nu}}{m}$$

(8)

Replacing (8) into (6), we get back (5).

Let us consider first the massive case. Using (7) we can fix the gauge $v = 1$. Introducing $mdt = d\tau$, we get the action:

$$L_1 = \frac{1}{2} m \int d\tau \left( 1 - (g_{\mu\nu} + \kappa_2' \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu + \frac{1 + (g_{\mu\nu} + \kappa_2' \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu}{2g_{\alpha\beta} \dot{x}^\alpha \dot{x}^\beta} \left(1 + g_{\lambda\rho} \dot{x}^\lambda \dot{x}^\rho\right) \right)$$

(9)

plus the constraint obtained from the equation of motion for $v$:

$$g_{\mu\nu} \dot{x}^\mu \dot{x}^\nu = -1$$

(10)

From $L_1$ the equation of motion for massive particles is derived. We define $\bar{g}_{\mu\nu} = g_{\mu\nu} + \kappa_2' \tilde{g}_{\mu\nu}$.

$$\frac{d(\dot{x}^\mu \dot{x}^\nu \bar{g}_{\mu\nu} \dot{x}^\alpha \dot{x}^\beta \bar{g}_{\alpha\beta})}{d\tau} - \frac{1}{2} \dot{x}^\mu \dot{x}^\nu \bar{g}_{\mu\nu} \dot{x}^\gamma \bar{g}_{\beta\gamma} \alpha - \dot{x}^\mu \dot{x}^\nu \bar{g}_{\mu\nu} \alpha = 0$$

(11)
We will discuss the motion of massive particles elsewhere.

The action for massless particles is:

\[
L_0 = \frac{1}{4} \int dt \left( -v^{-1} (g_{\mu\nu} + \kappa_2 \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu \right) \tag{12}
\]

In the gauge \( v = 1 \), we get:

\[
L_0 = -\frac{1}{4} \int dt (g_{\mu\nu} + \kappa_2 \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu \tag{13}
\]

plus the equation of motion for \( v \) evaluated at \( v = 1 \): \((g_{\mu\nu} + \kappa_2 \tilde{g}_{\mu\nu}) \dot{x}^\mu \dot{x}^\nu = 0 \)

So, the massless particle moves in a null geodesic of \( g_{\mu\nu} = g_{\mu\nu} + \kappa_2 \tilde{g}_{\mu\nu} \).

4. Distances and time intervals

In this section, we define the measurement of time and distances in the model.

In GR the geodesic equation preserves the proper time of the particle along the trajectory. Equation \( (11) \) satisfies the same property: Along the trajectory \( \dot{x}^\mu \dot{x}^\nu g_{\mu\nu} \) is constant. Therefore we define proper time using the original metric \( g_{\mu\nu} \).

\[
d\tau = \sqrt{-g_{\mu\nu} dx^\mu dx^\nu} = \sqrt{-g_{00} dx^0 (dx^1 = 0)} \tag{14}
\]

Following [25], we consider the motion of light rays along infinitesimally near trajectories and \( (14) \) to get the three dimensional metric:

\[
dl^2 = \gamma_{ij} dx^i dx^j , \quad \gamma_{ij} = \frac{g_{00} (g_{ij} - g_{0i} g_{0j})}{g_{00}} \tag{15}
\]

That is, we measure proper time using the metric \( g_{\mu\nu} \) but the space geometry is determined by both metrics. In this model massive particles do not move on geodesics of a four dimensional metric. Only massless particles move on a null geodesic of \( g_{\mu\nu} \). So, delta gravity is not a metric theory.

5. The Newtonian limit

The motion of a non relativistic particle in a weak static gravitational field is obtained using \( g_{\mu\nu} = \text{diag} \left(-1 - 2U\epsilon, 1 - 2U\epsilon, 1 - 2U\epsilon, 1 - 2U\epsilon\right) \), which solves Einstein equations to first order in \( \epsilon \) if \( \nabla^2 U = \frac{1}{2} \kappa \rho \).

The solution for \( \tilde{g}_{\mu\nu} \) is \( \tilde{g}_{\mu\nu} = \text{diag} \left( \epsilon \tilde{U}, 1 + \epsilon \left( \tilde{U} - 2U\right), 1 + \epsilon \left( \tilde{U} - 2U\right), 1 + \epsilon \left( \tilde{U} - 2U\right) \right) \).

Solving \( (3) \), to first order in \( \epsilon \) we get \( \nabla^2 \tilde{U} = \frac{1}{2} \kappa \rho \).

To recover the Minkowsky metric far from the sources, \( \rho \to 0 \), we must require: \( U \to 0, \tilde{U} \to -\epsilon^{-1} \).

(11) implies \( \frac{\partial^2 x^i}{\partial \epsilon^2} = -\phi \) \( \phi = U - \kappa_2 (2U + \tilde{U}) \).

The Newtonian potential satisfies \( \nabla^2 \phi = \frac{\kappa}{2} (1 - 3\kappa_2) \rho, |\kappa_2| \ll 1 \). The whole effect is a small redefinition of Newton constant.

Gravitational red shift experiments can be used to put bounds on \( \kappa_2 \). According to \( (14) \), the shift in frequency of a source located at \( x_1 \), compared to the same source located at \( x_2 \) due to the change in gravitational potential is:

\[
\frac{\Delta \nu}{\nu} = \frac{\phi_N(x_2) - \phi_N(x_1)}{\nu} \quad \text{where} \quad \phi_N \text{ is the usual Newtonian potential, computed with } \kappa \text{ as Newton constant.}
\]

From [26] we get \( \frac{\Delta \nu}{\nu} = (1 + 2.5 \pm 70 \times 10^{-6}) (\phi_S - \phi_E + \ldots) \), where \( \phi_S \) is the gravitational potential at the spacecraft.
position and $\varphi_E$ is the gravitational potential on Earth. ... accounts for additional effects not related to the gravitational potential. We can ascribe the uncertainty of the experiment to $\kappa'_2$, to get the bound:

$$|\kappa'_2| < 24 \times 10^{-6}$$

This bound is conservative because the Newton constant itself has a larger error [27]: $G = 6.67428 \pm 0.00067 \times 10^{-11} \text{m}^3 \text{kg}^{-1} \text{s}^{-2}$.

In our description of the evolution of the Universe, the value of $\kappa'_2$ is not important, so we will keep it arbitrary for the time being.

6. Friedman-Robertson-Walker (FRW) metric

This is the main section of the paper. We discuss the equations of motion for the Universe described by the FRW metric. We use spatial curvature equal to zero to agree with cosmological observations.

In this paper we will deal only with a perfect fluid, since rotational and translational invariance implies that the energy-momentum tensor of the Universe has this form. The energy momentum tensor for a perfect fluid is [8]:

$$T_{\mu\nu} = p g_{\mu\nu} + (p + \rho) U_\mu U_\nu, g^{\mu\nu}U_\mu U_\nu = -1$$  \hspace{1cm} (16)

Then:

$$\delta T_{\mu\nu} \delta g_{\gamma\sigma} = p \tilde{g}^{\gamma\sigma} + \frac{1}{2} (p + \rho) (U^\gamma U_\sigma \tilde{g}^{\mu\nu} + U^\sigma U_\mu \tilde{g}^{\gamma\nu})$$  \hspace{1cm} (17)

In this case, assuming flat three dimensional metric:

$$-ds^2 = dt^2 - R(t)^2 \left\{dr^2 + r^2 d\theta^2 + r^2 \sin^2 \theta d\phi^2\right\}$$

$$-d\tilde{s}^2 = \tilde{A}(t) dt^2 - \tilde{B}(t) \left\{dr^2 + r^2 d\theta^2 + r^2 \sin^2 \theta d\phi^2\right\}$$

Using (11, 14), we can check that these are co-mobile coordinates and the proper time interval $dt$ for a co-moving clock is just $dt$, so $t$ is the time measured in the rest frame of a co-moving clock. Equations (3, 17) give:

$$-\dot{R} \dot{B} - \frac{1}{2} p R \dot{B} + \frac{1}{2} R^{-1} \dot{R}^2 \tilde{B} - \frac{1}{6} \rho R^3 \ddot{A} + \frac{3}{2} R \ddot{R} \ddot{A} = 0$$

$$-p \ddot{B} - 2 \ddot{B} - R^{-2} R \ddot{R} \ddot{B} + 2R^{-1}R\ddot{B} + 2R^{-1} R \ddot{B} + \rho R^2 \ddot{A} + R^2 \dddot{A} + 2 R^{\dot{R}} \dot{A} + 2R \dddot{R} = 0$$  \hspace{1cm} (18)

Einstein’s equations are:

$$\frac{3}{R^2} \left(\frac{d}{dt} \frac{R^2}{R^2} \right)^2 = \kappa \rho - 2 \left(\frac{d}{dt} \frac{R^2}{R^2} \right) + \left(\frac{d}{dt} \frac{R^2}{R^2} \right)^2 = -\kappa R^2 \rho$$

We use the equation of state $p = w\rho$, to get, for $w \neq -1$:

$$R = R_0 \left(\frac{t^2}{t_0^2} \right)^{\frac{1}{w+1}}, \dot{A} = 3w l_2 b^{\frac{3}{w+1}}$$

$$\dot{B} = R_0^2 l_2 b, b = \frac{4}{3w + 3} + \frac{w - 1}{w + 1}$$  \hspace{1cm} (19)

$l_2$ is a free parameter.
7. Red Shift
To make the usual connection between redshift and the scale factor, we consider light waves traveling from \( r = r_1 \) to \( r = 0 \), along the \( r \) direction with fixed \( \theta, \phi \). Photons moves on a null geodesic of \( \mathbf{g} \):

\[
0 = -(1 + \kappa_2^2 A) dt^2 + (R^2 + \kappa_2^2 B)(dr^2 + r^2 d\theta^2 + r^2 \sin^2 \theta d\phi^2)
\]

So,

\[
\int_{t_1}^{t_0} dt \sqrt{\frac{1 + \kappa_2^2 A}{R^2 + \kappa_2^2 B}} = r_1
\]

A typical galaxy will have fixed \( r_1, \theta_1, \phi_1 \). If a second wave crest is emitted at \( t = t_1 + \delta t_1 \) from \( r = r_1 \), it will reach \( r = 0 \) at \( t_0 + \delta t_0 \), where

\[
\int_{t_1 + \delta t_1}^{t_0 + \delta t_0} dt \sqrt{\frac{1 + \kappa_2^2 A}{R^2 + \kappa_2^2 B}} = r_1
\]

Therefore, for \( \delta t_1, \delta t_0 \) small, which is true for light waves, we have:

\[
\delta t_0 \sqrt{\frac{1 + \kappa_2^2 A}{R^2 + \kappa_2^2 B}(t_0)} = \delta t_1 \sqrt{\frac{1 + \kappa_2^2 A}{R^2 + \kappa_2^2 B}(t_1)}
\]

Introduce:

\[
\tilde{R}(t) = \sqrt{\frac{R^2 + \kappa_2^2 B}{1 + \kappa_2^2 A}(t)}
\]

We get \( \frac{\delta t_0}{\delta t_1} = \frac{\tilde{R}(t_0)}{\tilde{R}(t_1)} \). A crucial point is that, according to equation (14), \( \delta t \) measure the change in proper time. That is: \( \nu_0 = \frac{\tilde{R}(t_0)}{\tilde{R}(t_1)} \), where \( \nu_0 \) is the light frequency detected at \( r = 0 \) corresponding to a source emission at frequency \( \nu_1 \). Or in terms of the redshift parameter \( z \), defined as the fractional increase of the wavelength \( \lambda \):

\[
z = \frac{\tilde{R}(t_0)}{\tilde{R}(t_1)} - 1 = \frac{\lambda_0 - \lambda_1}{\lambda_1}
\]

We see that \( \tilde{R} \) replaces the usual scale factor \( R \) in the computation of \( z \).

8. Luminosity distance
Let us consider a mirror of radius \( b \) that is receiving light from a distant source. The photons that reach the mirror are inside a cone of half-angle \( \varepsilon \) with origin at the source.

Let us compute \( \varepsilon \).The light path of rays coming from a far away source at \( \bar{x}_1 \) is given by \( \vec{x}(\rho) = \rho \hat{n} + \vec{x}_1, \rho > 0 \) is a parameter and \( \hat{n} \) is the direction of the light ray.The path reaches us at \( \vec{x} = \vec{0} \) for \( \rho = |\vec{x}_1| = r_1 \). Write \( \hat{n} = -\hat{x}_1 + \vec{\varepsilon} \). Since \( \hat{n}, \hat{x}_1 \) have modulus 1, \( \varepsilon = |\vec{\varepsilon}| << 1 \) is precisely the angle between \( -\hat{x}_1 \) and \( \hat{n} \) at the source.The impact parameter is the proper distance of the path from the origin, when \( \rho = |\vec{x}_1| \). The proper distance is determined by the 3-dimensional metric (15). That is \( b = \tilde{R}(t_0) r_1 \theta = \tilde{R}(t_0) r_1 \varepsilon \), i.e. \( \varepsilon = \frac{b}{\tilde{R}(t_0) r_1} \).

Then the solid angle of the cone is \( \pi \varepsilon^2 = \frac{A}{r_1^2 \tilde{R}(t_0)^2} \), where \( A = \pi b^2 \) is the proper area of the mirror.The fraction of all isotropically emitted photons that reach the mirror is \( f = \frac{A}{4\pi r_1^2 \tilde{R}(t_0)^2} \).

Each photon carries an energy \( h\nu_1 \) at the source and \( h\nu_0 \) at the mirror. Photons emitted at
intervals $\delta t_1$ will arrive at intervals $\delta t_0$. We have $\frac{\delta a}{a_0} = \frac{\dot{R}(t_0)}{R(t_1)} \frac{\delta t_0}{\delta t_1}$. Therefore the power at the mirror is $P_0 = L \frac{\dot{R}(t_1)^2}{R(t_0)^2} f$, where $L$ is the luminosity of the source. The apparent luminosity is $l = \frac{P_0}{A} = L \frac{\dot{R}(t_1)^2}{R(t_0)^2} \frac{1}{4\pi^2 R(t_0)^2}$. In Euclidean space, the luminosity decreases with distance $d$ according to $l = \frac{L}{4\pi d^2}$. This permits to define the luminosity distance $d_L = \sqrt{\frac{L}{4\pi}} = \frac{R(t_0)^2}{R(t_1)}$. Using (21) we can write this in terms of the red shift:

$$d_L = (1 + z) \int_0^z \frac{dz'}{H(z')} = \frac{\dot{R}}{R}$$  \quad (24)

9. Supernova Ia data

The supernova Ia data gives, $m$ (apparent or effective magnitude) as a function of $z$. This is related to distance $d_L$ by $m = M + 5 \log(d_L/R_0)$. Here $M$ is common to all supernova and $m$ changes with $d_L$ alone.

We compare $\delta$ gravity to General Relativity (GR) with a cosmological constant:

$$H^2 = H_0^2(\Omega_m (1+z)^3 + (1 - \Omega_m)), \Omega_\Lambda = 1 - \Omega_m$$

Notice that $\dot{A} = 0$ for $w = 0$ in (19). So, it seems that we cannot fit the supernova data. However $w = 0$ is not the only component of the Universe. The massless particles that decoupled earlier still remain. It means that the true $w$ is between $0 \leq w < \frac{1}{3}$, but very close to $w = 0$. So, we will fit the data with $w = 0.1, 0.01, 0.001$ and see how sensitive the predictions are to the value of $w$.

Using data from Essence[28], we notice that $R^2$ test changes very little for the chosen sequence of $w$’s. Each fit determines the best $l_2$ for a given $w$. In this way we see that $l_2$ scales like $l_2 \sim \frac{a}{3w}$, $a$ being independent of $w$. As an approximation to the limit $w = 0$, we get:

$$\hat{R}(t) = R(t) \frac{\sqrt{a}}{\sqrt{a} - t}$$  \quad (25)

$\sqrt{\frac{1}{3w}}$ renormalizes the derivative of $\hat{R}$ at $t = 0$. It is not divergent, because for $t \to 0$, $w \to \frac{1}{3}$. $a$ is a free parameter determined by the best fit to the data.

Of course, the complete model must include the contribution of normal matter ($w = 0$) plus relativistic matter ($w = \frac{1}{3}$). But, at later times, the data should tend to (25).

Let us fit the data to the simple scaling model (25).

We get:

$$\Omega_m = 0.22 \pm 0.03, M = 43.29 \pm 0.03, \chi^2(\text{perpoint}) = 1.0328, \text{ General Relativity}$$

$$a = 2.21 \pm 0.12, M = 43.45 \pm 0.06, \chi^2(\text{perpoint}) = 1.0327, \text{ Delta Gravity}$$

$\delta$-gravity with non-relativistic (NR) matter alone give a fit to the data as good as GR with NR matter plus a cosmological constant.

According to the fit to data, a Big Rip will happen at $t = 2.21049$ in unities of $t_0$(today). It is a similar scenario as in [23].

Finally, we want to point out that since for $t \to 0$, we have $w \to \frac{1}{3}$, then $\hat{R}(t) = R(t)$. Therefore the accelerated expansion is slower than (25) when we include both matter and radiation in the model.
10. Conclusions and Open Problems

Delta Gravity agrees with GR when \( T_{\mu\nu} = 0 \), imposing same boundary conditions for both tensor fields. In particular, the causal structure of delta gravity in vacuum is the same as in GR, since in this case the action (5) is proportional to the geodesic action in GR.

We recover the Newtonian approximation.

In a homogeneous and isotropic universe, we get accelerated expansion without a cosmological constant or additional scalar fields.

The computation of PPN(Post Newtonian) parameters is in progress, but we do not expect large departures from general relativity, because the Newtonian limit is the right one, as explained in section 6. Moreover the interstellar space has very small matter densities, so \( \delta \)-gravity must give GR values for the PPN parameters(See comments after equation(4)). Additionally, please notice that all \( \tilde{g} \) contributions are multiplied by the small parameter \( \kappa'^2 \) of the order of \( 10^{-15} \) or less, so they are very small in the solar system.

Stellar evolution will not be changed from its Newtonian description, unless density of matter becomes very large. Even at the densities of white dwarfs the Poisson equation for the gravitational potential suffices.(See, for instance [8], chapter 11.3). \( \delta \)-gravity implies it, as it is shown in section 6. Higher densities which are present in neutron stars may provide new tests of \( \delta \)-gravity, since there we have to use the whole non-linear Einstein equations and the corresponding \( \delta \)-gravity equations. But for the inner regions of massive stars, data is very scarce.

Notice that equation (19) implies that \( \tilde{R} = R \) at the beginning of the Universe, when \( w = \frac{1}{3} \), corresponding to ultrarelativistic matter. That is, the accelerated expansion started at a later time, which is needed if we want to recover the observational data of density perturbations and growth of structures in the Universe. An earlier acceleration of the expansion would prevent the growth of density perturbations.

Work is in progress to compute the growth of density perturbations and the anisotropies in the CMBR. The comparison of these calculations with the considerable amount of astronomical data that will be available in the near future will be a very stringent test of the present gravitational model.

It was noticed in [20] that the Hamiltonian of delta models is not bounded from below. Phantoms cosmological models [22], [23] also have this property. Although it is not clear whether this problem will subsist in a diffeomorphism invariant model as delta gravity or not, we want to mention some ways out of the difficulty.

a) Delta gravity is a gauge theory. Moreover it is diffeomorphism invariant. Thus the canonical Hamiltonian vanishes identically. It may be possible to truncate the Hilbert space, using the BRST formalism, to define a model with a Hamiltonian bounded from below. This is a difficult task that goes far beyond the present paper, but should be pursued in a future work.

b) In a supersymmetric model we have \( H = Q^2 \), where \( H \) is the Hamiltonian and \( Q \) is the hermitian supersymmetry charge. Thus the Hamiltonian is bounded from below. So, we expect that a delta supergravity model has a Hamiltonian bounded from below.

c) A Delta model has more symmetries than the original model. This permits to bound the Hamiltonian for a given value of a conserved quantity. We explain this in Appendix B.

Acknowledgements JA wants to thank the organizers of DSU2011 for a very stimulating experience at Beijing. The work of JA is partially supported by VRAID/DID/46/2010 and Fondecyt 1110378. He wants to thank R. Avila and P. González for several useful remarks; The author acknowledges interesting conversations with L. Infante, G. Palma, M. Bañados and A. Clocchiatti. In particular, JA wants to thank A. Clocchiatti for pointing out the data in [28]. Finally, JA wants to thank J. Gamboa for a careful reading of the manuscript.

2. Appendix A Review of δ-symmetries
Assume we have a group of transformations acting on the variables $y$ with infinitesimal parameters $\epsilon$. That is:

$$\delta y^i = \Lambda^i_\alpha(y)\epsilon^\alpha$$

We define the $\delta$ transformation by:

$$\delta \bar{y}^i = \Lambda^i_\alpha(y)\bar{y}^j\epsilon^\alpha + \Lambda^i_\alpha(y)\epsilon^\alpha$$

$$k^i = \frac{\partial k}{\partial y^i}.$$ 

Notice that, we have introduced a new field $\bar{y}^i$ and a new transformation with parameter $\epsilon^\alpha$. It is easy to see that (26, 27) form a closed algebra.

An invariant action under the extended symmetry is built in the same way. We assume that
$S(y)$ is invariant under (26):

$$\frac{\delta S}{\delta y^j} \Lambda^i_\alpha (y) = 0, \forall y, \text{all } \alpha \tag{28}$$

Then:

$$\bar{S}(y, \bar{y}) = S(y) + \frac{\delta S}{\delta y^j} \bar{y}^j$$

is invariant under (26, 27).

Proof:

$$\delta \bar{S}(y, \bar{y}) = \frac{\delta S}{\delta y^j} \Lambda^i_\alpha (y) \epsilon^\alpha + \frac{\delta^2 S}{\delta y^i \delta y^j} \Lambda^i_\alpha (y) \epsilon^\alpha \bar{y}^i + \frac{\delta S}{\delta y^j} (\Lambda^i_\alpha (y) \bar{y}^j \epsilon^\alpha + \Lambda^i_\alpha (y) \epsilon^\alpha) =$$

$$0 + \frac{\delta^2 S}{\delta y^i \delta y^j} \Lambda^i_\alpha (y) \bar{y}^i + \frac{\delta S}{\delta y^j} (\Lambda^i_\alpha (y) \bar{y}^j) \epsilon^\alpha + 0 \epsilon^\alpha =$$

$$\left( \frac{\delta^2 S}{\delta y^j \delta y^j} \Lambda^i_\alpha (y) + \frac{\delta S}{\delta y^j} \Lambda^i_\alpha (y) \right) \epsilon^\alpha \bar{y}^j = 0$$

Last equality follows from equation (28).

Being careful with signs of permutations, these results are true for anti-commuting $y, \epsilon$ as well. In particular, super-symmetric transformations can be generalized to a $\delta$- symmetry.

Other generalizations are possible. Suppose we have canonical transformations generated by $\epsilon(x, p)$:

$$\delta F = (\epsilon, F) \leftrightarrow \delta F = (\epsilon, F) \tag{29}$$

equations (26, 27) are particular cases of (29). $(A, B)$ is the Poisson bracket. Now we can prove the closure of the algebra in a more general context.

$$[\delta_{\beta}, \delta_{\alpha}] F = (\delta_{\beta}(\alpha, F) - \alpha \leftrightarrow \beta) = (\alpha, (\beta, F)) = \delta(\alpha, \beta, F) = \delta(\alpha, \beta, F)$$

$$[\delta_{\beta}, \delta_{\alpha}] \bar{F} = (\delta_{\beta}(\alpha, \bar{F}) - \alpha \leftrightarrow \beta) = (\alpha, (\beta, \bar{F})) = \delta(\alpha, \beta, \bar{F}) = \delta(\alpha, \beta, \bar{F})$$

$$[\delta_{\alpha}, \delta_{\beta}] F = 0$$

$$[\delta_{\alpha}, \delta_{\beta}] \bar{F} = (\delta_{\alpha}(\beta, F) - \beta \leftrightarrow \alpha) = \delta(\alpha, \beta, F) = (\bar{F}(\alpha, \beta)) = \delta(\bar{F}(\alpha, \beta))$$

$$[\delta_{\alpha}, \delta_{\beta}] \bar{F} = \delta(\alpha, \beta, F) - \bar{\alpha} \leftrightarrow \beta = 0$$

Replacing Poisson bracket by commutators is the realization of the algebra we used in [20].

12. Appendix B: The Delta Harmonic Oscillator

$$L = \frac{1}{2} x^2 - \frac{1}{2} \omega^2 x^2 + \dot{x} \dot{y} - \omega^2 x y$$

The canonical variables are:

$$p_x = \dot{x} + \dot{y}$$

$$p_y = \dot{x}$$

$$H = \dot{x}(\dot{x} + \dot{y}) + \dot{y} \dot{x} - L = H_0 + \dot{x} \dot{y} + \omega^2 x y$$

$$H_0 = \frac{1}{2} p_y^2 + \frac{1}{2} \omega^2 x^2 \tag{30}$$

We know that $H_0$ is conserved, because the model satisfies the equations of motion for $x$. Since $H$ is conserved, we have that $Q$ is conserved.
\[ Q = \dot{x}y + \omega^2 xy \]

Since \( H_0 \) is greater or equal than zero. \( H \) is bounded from below by the value of the conserved quantity \( Q \).

This is a generic feature of delta models. The Hamiltonian is bounded from below, for a given value of a conserved quantity \( Q \), if the Hamiltonian of the original model is bounded from below.
