Abstract: Clenbuterol is a \(\beta_2\)-agonist used in the veterinary treatment of asthma in several countries. The drug is listed on the World Antidoping Agency’s prohibited list due to its effect on increased protein synthesis in the body. However, racemic clenbuterol has recently been shown to reduce the risk of Parkinson’s disease. In order to reveal which one (or both) of the enantiomers that cause this effect, pure enantiomers need to be separately studied.

\((R)\)-1-(4-Amino-3,5-dichlorophenyl)-2-bromoethan-1-ol has been synthesised in 93% enantiomeric excess (ee) by asymmetric reduction of the corresponding ketone catalysed by a ketoreductase and nicotinamide adenine dinucleotide phosphate (NADPH) as the cofactor in dimethyl sulfoxide (DMSO). \((S)\)-\(N\)-(2,6-Dichloro-4-(1-hydroxyethyl)phenyl)acetamide has been synthesised in >98% ee by the same system. Both synthons are potential precursors for clenbuterol enantiomers.

Keywords: \((R)\)-1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol; \((S)\)-\(N\)-(2,6-dichloro-4-(1-hydroxyethyl)phenyl)acetamide; clenbuterol; ketoreductase; chiral chromatography

1. Introduction

The need for enantiopure compounds for the treatment of human diseases and combatting microbial attacks on, for example, crops can be explained by the fact that all living organisms in nature are chiral. Protein biosynthesis and most metabolic processes are mediated by enzymes that are specific for a particular isomeric form of a certain substrate, and this is essential for ensuring the high degree of three-dimensional organization that is found in structures within cells. It is presumably evolutionary chance that has determined that life is based on L- rather than D-amino acids [1].

When drug–receptor interactions are considered, it is postulated that the lower the effective dose of a drug, the greater the difference in the pharmacological effect of the optical isomers [2]. The ratio of the more active enantiomer (eutomer) compared to the less active enantiomer (distomer) is defined as the eudismic ratio; the higher the eudismic ratio is, the higher the effectiveness of the drug [3].

The \(\beta_2\)-agonists clenbuterol and salbutamol are drugs used in the treatment of for instance angina pectoris, asthma, and other disorders related to the sympathetic nervous system [4,5]. \(\beta_2\)-Receptors are mainly found in the bronchi, bronchioles, and gastrointestinal tract, and one of their main actions is the relaxation of smooth muscles (bronchodilation) [6]. Racemic clenbuterol and salbutamol are shown in Figure 1. Clenbuterol is marketed with a racemic active pharmaceutical ingredient (API), while salbutamol is marketed both as the racemate and as Xopenex \(^\circledR\), with the R-enantiomer as the API. The \((R)\)-1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol (\((R)\)-2a) and \((S)\)-\(N\)-(2,6-dichloro-4-(1-hydroxyethyl)phenyl)acetamide (\((S)\)-6a) alcohols are also shown in Figure 1.
Clenbuterol: $X_1 = t$-BuNH, $X_2 = $Cl, $X_3 = $Cl, $R = NH_2$
Salbutamol: $X_1 = t$-BuNH, $X_2 = $CH_2OH, $X_3 = $H, $R = OH$

(R)-2: $X_1 = Br, X_2 = $Cl, $X_3 = $Cl, $R = NH_2$
(S)-6: $X_1 = $H, $X_2 = $Cl, $X_3 = $Cl, $R = $NHAc

Figure 1. Structures of racemic $\beta_2$-agonists clenbuterol and salbutamol and (R)-1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol ((R)-2a) and (S)-N-(2,6-dichloro-4-(1-hydroxyethyl)phenyl)acetamide ((S)-6a).

Clenbuterol (Ventipulmin®, Boehringer Ingelheim Vetmedica, Inc., Duluth, GA, USA) is a long-acting, selective $\beta_2$-agonist with anabolic properties used in the treatment of shock and airway-obstructing diseases in veterinary medicine [7,8]. It has not been approved by the U.S. Food and Drug Administration (FDA) for human or food-producing animals use, although it is illegally added to livestock feed to promote the growth of lean meat [9]. Clenbuterol can reduce body fat, and it is extensively used by athletes and bodybuilders even though it is listed on the World Antidoping Agency’s prohibited list [10]. In addition to the desired effects of smooth-muscle relaxation, clenbuterol can cause several side effects, such as heart palpitations, muscle tremors, and nervousness [8].

Previously, it was reported that (S)-clenbuterol had neuroprotective properties, reduced blood pressure, and enhanced blood-glucose levels in rats. While (R)-clenbuterol did not promote these properties, it was found that it caused decreased motor activity, head twitches, and tremors [11,12]. Upon examination of human urine of participants who ingested racemic clenbuterol, it was found that the S-enantiomer was retained for longer in the body [13]. Recently, Mittal et al. found that the brains of patients with Parkinson’s disease contained accumulations of $\alpha$-synuclein protein, the so-called Lewy bodies. $\beta_2$-agonists metaproterenol, clenbuterol, and salbutamol lowered the levels of $\alpha$-synuclein gene mRNA and $\alpha$-synuclein protein levels in human SK-N-MC neuroblastoma cells [14]. Only racemic compounds have been studied, but pure enantiomers of the drugs should be independently studied in order to reveal if enantiomers would show different effects.

Racemic clenbuterol has been synthesised through the incorporation of carbon monoxide in aryl iodides [15], while racemic $^{13}$C-labeled clenbuterol has been synthesised from acetanilide [16]. Enantiopure (R)-1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol, a precursor for (R)-clenbuterol, has been synthesized through an asymmetric reduction of the parent ketone, catalysed by an alcohol dehydrogenase from Rhodococcus erythropolis. No enantiomeric ratio was reported [17].

Our attempts to synthesize enantiopure precursors for (R)-clenbuterol include both lipase catalysed kinetic resolutions of racemates and asymmetric reductions of substituted acetophenones catalysed by ketoreductases. Previously, we utilised chemoenzymatic methods in syntheses of enantiopure building blocks for compounds that are related to clenbuterol [18,19].

2. Results

In order to obtain a precursor for enantiopure (R)-clenbuterol, bromo alcohol 1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol (3) was synthesised in a 45% yield (Scheme 1) for the purpose of performing lipase-catalysed asymmetric resolution with lipases suitable for industrial-scale production. Bromination of substrate ketone 1 produced bromoketone 2 in an 86% yield. Various methods for the $\alpha$-bromination of ketone 1 were performed: Addition of $N$-bromosuccinimide (NBS) (1.0 eq.) to 1 with para-toluenesulfonic acid (0.1 eq.) in methanol at 30 °C produced brominated ketone 2 in an 11% yield. Bromination of 1 with bromine (1.1 eq.) in acetic acid at 60 °C gave ketone 2 in a 27% yield, while reacting substrate 1 with NBS (1.3 eq.) catalysed by silica gel (10% w/w) in refluxing methanol...
produced 2 in a 30% yield. Finally, we were able to produce α-bromo ketone 2 in an 86% yield by the slow addition of Br₂ (1.1 eq.) to 1 in dichloromethane and methanol (2:1 v/v) at room temperature. Subsequent reduction of 2 with sodium borohydride gave 3 in a 45% yield.

Scheme 1. Synthesis of 1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-one (2) and 1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol (3) from commercial 1-(4-amino-3,5-dichlorophenyl)ethan-1-one (1).

2.1. Kinetic Resolutions

The kinetic resolutions of 3 were performed in dichloromethane with vinyl butanoate as the acyl donor catalysed by commercial immobilised lipases A and B from Candida antarctica (CALA and CALB, Sigma-Aldrich, Oslo, Norway). The reactions showed no conversion after five days. We also attempted to resolve racemic clenbuterol with CALA and CALB from Sigma-Aldrich and vinyl butanoate as the acyl donor in tetrahydrofuran, Scheme 2. However, these reactions resulted in several acylation products after five days and the enzyme showed low enantioselectivity.

\]

Scheme 2. Kinetic resolution of clenbuterol catalysed by commercial immobilised lipases A and B from Candida antarctica (CALA and CALB) in dry tetrahydrofuran (THF) with vinyl butanoate (VB) as acyl donor, showed several acylation products. The E-value for the desired acylation was \( E = 1.3 \) after five days.

The electropherogram from the CALA-catalysed kinetic resolution of clenbuterol after 78 h (Figure 2) shows the peaks of (R)-clenbuterol at retention times \( t_R \) 9.70 min and (S)-clenbuterol at \( t_R \) 11.50 min, and the butanoic esters of (S)-clenbuterol at \( t_R \) 12.52 min and ester of (R)-clenbuterol at \( t_R \) 12.98 min. Elution orders are consistent with previously reported retention times [20]. The remaining peaks have not been identified, but are most likely the amide products from the acylation of the aromatic or aliphatic amines, which would produce two enantiomers each.

We anticipate that the α-bromo substituent in 3 could be one reason for the low selectivity and low reaction rate in the transesterification. In order to reveal the influence of an electron-rich substituent next to the stereocenter compared to bromine, transesterification of the propargyl alcohol 8 was performed in dry hexane with vinyl butanoate as the acyl donor and CALB as the catalyst (Scheme 3). The catalyst showed excellent enantioselectivity towards 8 after 2.5 h with an \( E \)-value >200 resulting in the conversion of (R)-8 to (R)-9 with no sign of (R)-8 on the chromatogram, giving (S)-8 in 99% ee. The reaction progress is shown in Figure 3. From this test reaction, it seems that either the chlorosubstituents in meta-position or the amino substituent in para-position on the benzene ring on 3 must be the reason for the low selectivity and slow esterifications of 3 and clenbuterol with CALB.
Asymmetrisations as the cosubstrate [21,22]. The cosolvent was DMSO in all asymmetrisation reactions. Tested in order to find a suitable system to regenerate nicotinamide adenine dinucleotide phosphate (NADP⁺), and we were successful with glucose-6-phosphate dehydrogenase with glucose-6-phosphate as the cosubstrate [21,22]. The cosolvent was DMSO in all asymmetrisation reactions.

Figure 2. Electropherogram from the kinetic resolution of clenbuterol, catalysed by CALA with vinyl butanoate in tetrahydrofuran. \( t_R \) (R)-Clenbuterol 9.70 min, \( t_R \) (S)-clenbuterol at 11.50 min, and the butanoate ester enantiomer of (R)- and (S)-clenbuterol at \( t_R \) 12.52 min and \( t_R \) 12.98 min, respectively.

Scheme 3. Kinetic resolution of 9 with CALB as the catalyst and vinyl butanoate in dry hexane.

Figure 3. Reaction progress of kinetic resolution of 8 with CALB in dry hexane with vinyl butanoate as acyl donor, \( E \geq 200 \). Both the butanoate ester enantiomer of 8, (R)-9 and the remaining alcohol (S)-8 were obtained in 99% ee. Chiral GLC and HPLC analyses gave \( ee_s \) - and \( ee_p \)-values from which the degree of conversion was calculated according to \( c = ee_s/(ee_s + ee_p) \).

2.2. Asymmetrisations

Asymmetrisations of ketones with suitable enzymes is another way of obtaining enantiopure compounds. Depending on the catalysts stereoselectivity towards a chosen substrate, a theoretical yield of 100% might be obtained. Scheme 4 shows the asymmetrisation of ketones 1, 2, and 4–7 with ketoreductase KRED 228 (Syncozymes Co., Ltd., Shanghai, China). Several regeneration systems were tested in order to find a suitable system to regenerate nicotinamide adenine dinucleotide phosphate (NADP⁺), and we were successful with glucose-6-phosphate dehydrogenase with glucose-6-phosphate as the cosubstrate [21,22].
Valuable enantiopure synthons could be synthesised from \((S)-6a\) (see suggestions in Scheme 5).

Through the reduction of 1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-one (2) with KRED 228, \((R)-2a\) was obtained in 93% ee. Reduction of \(N\)-(4-acetylphenyl)acetamide (5) by the same enzyme gave the S-alcohol \((S)-N\)-(4(1-hydroxyethyl)phenyl)acetamide, \((S)-5a\), in 73% ee. Reduction of \(N\)-(4-acetyl-2,6-dichlorophenyl)acetamide, 6, produced the S-alcohol \((S)-1\)-(4-amino-3,5-dichlorophenyl)ethan-1-ol, \((S)-6a\), in 98% ee. The reduction of \(N\)-(4-(2-bromoacetyl)phenyl)acetamide (7) gave an ee of 35% of the alcohol 7a, with \(R\)-configuration. The asymmetrisations of ketones 1 and 4 with the use of the same system were not successful. Asymmetrisations of the above-mentioned ketones were also performed with \(S.\) cerevicae and several alcohol dehydrogenases without any success. Valuable enantiopure synthons could be synthesised from \((S)-6a\) (see suggestions in Scheme 5).

\[
\begin{align*}

4: & \quad X_1 = H, X_2 = H, R = H \text{ n.r.} \\
5: & \quad X_1 = H, X_2 = H, R = Ac \\
6: & \quad X_1 = H, X_2 = Cl, R = Ac \\
7: & \quad X_1 = Br, X_2 = H, R = Ac \text{ n.r.}
\end{align*}
\]

\((S)-6a\) depends on the nucleophile (Nu).
3. Materials and Methods

Analytical-grade chemicals and solvents were purchased from Sigma-Aldrich (Oslo, Norway). HPLC-grade solvents were purchased from Sigma-Aldrich. Dry solvents (THF and CH\textsubscript{2}Cl\textsubscript{2}) were acquired from a MBraun MB-SPS-800 solvent purification system (MBraun, München, Germany). *Candida antarctica* lipase A (activity 1612 U/g; lot no. BCBR2259V), lipase B (activity 1800 U/g, lot no. BCBP3525V) were also purchased from Sigma-Aldrich. Crystalline KRED 228 (331.9 U/g, lot no. 20160509) was from Syncozymes Co., Ltd., (Shanghai, China). Flash chromatography was performed with silica gel from Sigma-Aldrich (pore size 60 Å, 230–400 mesh, 40–63 m particle size). Ketones 1, 4, 7 and clenbuterol were bought from Sigma-Aldrich (Oslo, Norway).

The enzyme-catalysed kinetic resolutions were performed in a New Brunswick G24 Environmental Incubator Shaker (New Brunswick Co. Inc., Edison, NJ, USA) at 30 °C and 200 or 300 rpm. Optical rotations ([α]D) were determined at 20 °C using a Perkin-Elmer 343 instrument (Perkin Elmer, Waltham, MA, USA) concentrations are given in g/100 mL. NMR spectra were recorded with a Bruker Avance DPX 400 instrument (Bruker, Rheinstetten, Germany) operating at 400 MHz for 1\textsuperscript{H} and 100 MHz for 13\textsuperscript{C}, respectively. Chemical shifts are in ppm rel. to tetramethylsilane (TMS) and coupling constants are in Hertz (Hz). High-resolution MS was performed on a WatersSynapt G2-S Q-TOF instrument (Waters MS Technologies, Manchester, UK) with Waters\textsuperscript{TM} Software (Masslynx V4.1 SCN871, (Waters MS Technologies, Manchester, UK). Sample ionization was performed with an ASAP probe (APCI).

3.1. Achiral Chromatographic Analyses

Achiral GLC analyses were performed on an Agilent 7890A gas chromatograph, with an Agilent 7890B autosampler, a split injector (280 °C), a 4 mm ID tap GW liner (Agilent Technologies, Santa Clara, CA, USA), a flame ionisation detector (FID, 280 °C). All analyses were performed on a Restek Rtx\textsuperscript{®}-1701 column (Crossbond\textsuperscript{®} 14\% cyanopropylphenyl–86\% dimethylpolysiloxane, 30 m × 0.32 mm ID, d\textsubscript{l} 0.25 μm, Restek Corporation, Bellefonte, PA, USA), carrier gas He 5.0, temp. prog.: 100–280 °C, gas pressure 8 psi, split flow 60 mL/min, temp prog 100–140 °C/10 °C min\textsuperscript{-1}, 140–180 °C/10 °C min\textsuperscript{-1} (5). Retention times: \textit{t}\textsubscript{R} (\textit{R})-3 = 25.363 min, \textit{t}\textsubscript{R} (\textit{S})-3, \textit{R} = 1.82.

Separation of enantiomers of 6\textsubscript{a} was performed on the same system: flow 75 mL min\textsuperscript{-1}, split flow 1:30, temp. prog.: 100–160 °C/10 °C min\textsuperscript{-1}, 160–170 °C/1 °C min\textsuperscript{-1}, 170–185 °C/0.5 °C min\textsuperscript{-1}. Retention times \textit{t}\textsubscript{R} (\textit{S})-6\textsubscript{a} = 44.467 min, \textit{t}\textsubscript{R} (\textit{R})-6\textsubscript{a} = 45.255 min, \textit{R} = 2.05.

The chiral GLC analyses of 8 were performed on a Varian 3380 gas chromatograph (Varian Inc., Mississauga, ON, USA), with a Varian CP-8410 autosampler, a split injector (200 °C), and a flame ionization detector (FID, 200 °C). The enantiomers of alcohol 8 and butanoic ester 9 were separated on a CP-Chirasil-Dex CB column (25 × 0.25 mm ID, d\textsubscript{l} 0.25 μm) from Agilent technologies. Carrier gas H\textsubscript{2} 5.0, gas pressure 8 psi, split flow 60 mL/min, temp prog 100–140 °C/10 °C min\textsuperscript{-1} (5), 140–180 °C/10 °C min\textsuperscript{-1} (7). Retention times \textit{t}\textsubscript{R} (\textit{S})-8 = 12.690 min, \textit{t}\textsubscript{R} (\textit{R})-8 = 12.901 min, \textit{R} = 3.5, \textit{t}\textsubscript{R} (\textit{S})-9 = 13.162 min, \textit{t}\textsubscript{R} (\textit{R})-9 = 14.359 min, \textit{R} > 1.5.
3.2.2. Chiral HPLC Analyses

HPLC analyses were performed on an Agilent HPLC 1100 system (Nacalai tesque, Japan) with a manual injector (Rheodyne 77245i/Agilent 20 µL loop), and a variable wavelength detector (VWD) set to 254 nm. Alcohol 5a was separated on a Chiralcel OD-H column (250 mm L × 4.6 mm ID, 5 µm particle size, Daicel, Chiral Technologies Europe, Illkirch-Graffenstaden, France). Eluent: 7% propan-2-ol/93% n-hexane; 1 mL min⁻¹, 1.5 µL injected. Retention times: \( t_R \) (R)-5a = 84.474 min, \( t_R \) (S)-5a = 91.765 min, \( R_S = 1.56 \).

Alcohol 7a was separated on the same column, eluent: 17% propan-2-ol/83% n-hexane; 1 mL min⁻¹, 2 µL injected. Retention times: \( t_R \) (R)-7a = 14.037 min, \( t_R \) (S)-7a = 17.035 min, \( R_S = 2.55 \).

3.2.3. Capillary Zone Electrophoresis

The chiral CZE analyses of clenbuterol and the corresponding butanoate were performed on a Beckman P/ACE MDQ capillary electrophoresis system (Beckman Coulter, Inc., Brea, CA, USA) in a fused silica capillary (31 cm × 50 µm, 21 cm to the detection window) with a diode array detector (DAD, 214 nm). Running buffer: pH 2.5 phosphate buffer (0.100 M), chiral selector: highly sulfonated β-cyclodextrin (5% w/v). Injection mode: hydrodynamic injection (0.5 psi for 5 s), separations voltage: −10 kV. Migration times: \( t_M \) (R)-clenbuterol 9.708 min, \( t_M \) (S)-clenbuterol at 11.504 min, \( t_M \) butanoates: \( t_M \) (R)-ester 12.521 min, \( t_M \) (S)-ester 12.988 min.

3.3. Determination of Enantiomeric Excess (ee), Conversion (c), and Enantiomeric Ratio (E)

Chiral GLC and HPLC analyses gave ee values from which the degree of conversion was calculated according to \( c = \frac{ee_s}{ee_s + ee_p} \). Enantiomeric ratios, E, were calculated based on ping-pong bi-bi kinetics using the computer program E and K Calculator 2.1b0 PPC (Department of chemistry, NTNU, Trondheim, Norway) [23]. Two or more replicates of the transesterification and asymmetrisation reactions were performed.

3.4. Absolute Configurations

The absolute configurations of (R)-2a, (S)-6a, and (R)-9 were determined by comparing the elution orders of the enantiomers with GLC elution orders of similar enantiopure compounds synthesised from (S)-epichlorohydrin. Elution orders on Daicel Chiralcel OD-H of the faster reacting enantiomers were the same [18,24,25]. Optical rotation values of (R)-2a, (S)-5, (S)-6a and (R)-7a have not been previously reported.

3.4.1. Synthesis of 1-(4-Amino-3,5-dichlorophenyl)-2-bromoethan-1-one (2)

To a solution of 1-(4-amino-3,5-dichlorophenyl)ethan-1-one (1) (1.10 g, 5.39 mmol) dissolved in CH₂Cl₂ (20 mL) and MeOH (10 mL), a solution of Br₂ (0.167 mL, 3.23 mmol) in CH₂Cl₂ (6 mL) was added at a rate of 40 drops per minute under strong agitation at RT. After an observed color change from bromine red to pale yellow, two additional portions of Br₂ (0.056 mL, 1.09 mmol) were added as described above. After the observed color change, the product was confirmed by TLC: \( R_f \) (2) = 0.58 (1:3 n-pentane: CH₂Cl₂). The reaction mixture was washed with satd. K₂CO₃ (2 × 40 mL) and brine (2 × 40 mL) before the organic layers were dried over MgSO₄ and filtered before the solvents were removed under reduced pressure. The crude compound was stirred in EtOH (4.4 mL) at 50 °C for 30 min, and for an additional 60 min at RT. The solids were filtered and recrystallised from EtOAc. The crystals were dried under vacuum overnight to afford 2 in 86% yield (1.04 g, 4.22 mmol) with 98% purity (GLC). ¹H NMR (400 MHz, CDCl₃): \( \delta \) 7.86 (s, 2H, H₂arom), 5.05 (s, 2H, NH₂), 2.31 (s, 2H, CH₂Br). ¹³C NMR (600 MHz, CDCl₃): \( \delta \) 188.0, 144.9, 129.2, 124.0, 188.9, 29.8. MS (TOF-ASAP): [M + H]+ 281.9088 m/z.
3.4.2. Synthesis of 1-(4-Amino-3,5-dichlorophenyl)-2-bromoethan-1-ol (3)

1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-one (2) (0.50 g, 1.77 mmol) dissolved in EtOH (12 mL) at 0 °C was added NaBH₄ (0.136 g, 3.60 mmol) in 4 portions over 20 min, under stirring. The reaction was slowly heated to RT, and the conversion was monitored by TLC: Rₜ (3) = 0.43 (1:3 n-pentane/CH₂Cl₂). After full conversion of the starting material, the reaction was quenched with dilute HCl until gas formation stopped. H₂O and EtOH were removed through azeotropic distillation, and the solids were dissolved in EtOAc (50 mL), and extracted with satd. NaHCO₃ (3 × 30 mL) and brine (3 × 30 mL). The aqueous layers were back extracted with EtOAc (2 × 50 mL), and the combined organic layers were dried over MgSO₄. The solvent was removed under reduced pressure, and the crude product was purified by flash chromatography (1:3 n-pentane/CH₂Cl₂) to afford 3 as a light-yellow solid in 44% yield (0.22 g, 0.77 mmol) in 95% purity (GLC). ¹H NMR (400 MHz, CDCl₃): δ 7.22 (s, 2H), 8.40–7.47 (dd, 1H, CHO, 3J_HH = 3.4 Hz, 8.9 Hz), 4.49 (s, 2H, NH₂), 3.59–3.55 (dd, 1H, CH-Br, 2J_HH = 10.5 Hz, 3J_HH = 3.4 Hz), 3.49–3.45 (dd, 1H, CH-Br, 3J_HH = 8.9 Hz, 2J_HH = 10.4 Hz). ¹³C NMR (400 MHz, CDCl₃): δ 140.1, 130.4, 125.6, 119.6, 72.6, 39.8. MS (TOF-ASAP) [M + H]⁺ 283.9241 m/z.

3.4.3. Synthesis of N-(4-Acetyl-phenyl)acetamide (5)

To a stirred solution of 1-(4-aminophenyl)ethan-1-one (0.53 g, 3.92 mmol) in CH₂Cl₂ (15 mL), a solution of AcCl (0.56 mL, 7.84 mmol) in CH₂Cl₂ (2 mL) was added dropwise at RT. After 5 min, a white precipitate started to form, and a solution of Et₃N (1.09 mL, 7.84 mmol) in CH₂Cl₂ (2 mL) was added dropwise, after which the solution cleared and turned a dark-yellow color. Full conversion was observed after 24 h by TLC: Rₜ (5) = 0.05 (1:4 EtOAc/n-pentane), and the solution was extracted with brine (3 × 15 mL). The aqueous layers were combined and extracted with EtOAc (2 × 15 mL), before the combined organic layers were dried over MgSO₄, filtered, and the solvent removed under reduced pressure. The crude product was recrystallized from EtOAc to afford 5 in 53% yield (0.37 g, 2.09 mmol) and 98% purity (GLC). ¹H NMR (600 MHz, CDCl₃): δ 7.95–7.93 (m, 2H), 7.62–7.61 (d, 2H, H₃arom, 2J_HH = 8.3 Hz), 7.42 (s, 1H, NHR), 2.58 (s, 3H, CO-CH₃). ¹³C NMR (600 MHz, CDCl₃): δ 196.9, 168.4, 142.2, 132.9, 129.8, 118.8, 26.4, 24.8. MS (TOF-ASAP) [M + H]⁺ 308.0867 m/z.

3.4.4. Synthesis of N-(4-Acetyl-2,6-dichlorophenyl)acetamide (6)

To a stirred solution of 1-(4-amino-3,5-dichlorophenyl)ethan-1-one (1) (6.00 g, 29.40 mmol) in CH₂Cl₂ (150 mL) AcCl (10.49 mL, 147.01 mmol) in CH₂Cl₂ (2 mL) was added dropwise at RT. The reaction was monitored by TLC. Rₜ (6) = 0.64 (1:4 EtOAc/n-pentane). After 48 h, full conversion was observed. The reaction mixture was washed with satd. K₂CO₃ (2 × 100 mL) and brine (2 × 100 mL), before the organic layers were collected and dried over anhydrous MgSO₄, filtered, and the solvent removed under reduced pressure. The crude product was recrystallized from EtOAc, and the purified compound dried in vacuo overnight to afford 6 as white crystals in 58% yield (4.20 g, 17.07 mmol) in 99% purity. ¹H NMR (400 MHz, CDCl₃): δ 7.86 (s, 2H, H₃arom), 7.42 (s, 1H, NHR), 2.56 (s, 3H, CO-CH₃), 2.22 (s, 3H, NCO-CH₃). ¹³C NMR (400 MHz, CDCl₃): δ 195.0, 168.4, 136.7, 136.4, 133.9, 128.3, 26.6, 23.2. MS (TOF-ASAP) [M + H]⁺ 246.0089 m/z.

3.4.5. Synthesis of 1-(4-Chlorophenyl)prop-2-yn-1-ol (8)

A solution of ethynylmagnesium bromide (0.50 M in THF; 18 mL, 9.0 mmol) was cooled to −20 °C. A solution of 4-chlorobenzaldehyde (1.0105 g, 7.19 mmol) in THF (2.5 mL) was added, and the flask washed out with THF (0.5 mL), which was then added to the reaction mixture. The cooling bath was removed, and the reaction mixture was stirred at room temperature (RT) for 5 min. The reaction was quenched by addition of satd. aq. NH₄Cl (10 mL), and the mixture was extracted with Et₂O (2 × 20 mL). The combined organic extracts were dried with Na₂SO₄, filtered, and concentrated in
The residue was purified by flash chromatography (gradient 1:10–1:3 EtOAc/pentane) to give 8 in 90% yield (1.078 g, 6.47 mmol) as a pale yellow oil. $R_f = 0.47$ (1:3 EtOAc/pentane). $^1$H NMR (400 MHz, CDCl$_3$): $\delta = 7.51–7.48$ (m, 2H, H$_{arom}$), 7.38–7.35 (m, 2H, H$_{arom}$), 5.45 (dd, $J = 6.1$, 2.1 Hz, CHC≡), 2.68 (d, $J = 2.2$ Hz, $\equiv$CH), 2.21 (d, $J = 6.1$ Hz, OH) ppm. $^1$H NMR spectroscopic data are in accordance with the literature data [26].

3.5. Kinetic Resolution of Secondary Alcohols with Lipases

3.5.1. Kinetic Resolution of Clenbuterol

1-(4-Amino-3,5-dichlorophenyl)-2-(tert-butylamino)ethan-1-ol (clenbuterol, 31.2 mg, 0.11 mmol) dissolved in dry THF (4.0 mL) was added 3 pellets of molecular sieve, and vinyl butanoate (0.058 mL, 0.55 mmol) before the mixture was incubated at 30 $^\circ$C and 200 rpm and the reaction was started by addition of lipase A from Candida antarctica (CALA, 55.4 mg). Aliquots of 100 L were collected every 30 min for the first 5 h, then every hour for 3 h, and every 24 h for 5 days. The solvent in the aliquots was removed with N$_2$ before 0.100 M pH 2.5 phosphate buffer (0.5 mL) was added, and the samples were analysed by chiral CE, from which the enantiomeric excess of (R)-clenbuterol was calculated to 11% ee.

3.5.2. Kinetic Resolution of 1-(4-Amino-3,5-dichlorophenyl)-2-bromoethan-1-ol (3)

To a solution of racemic 1-(4-amino-3,5-dichlorophenyl)-2-bromoethan-1-ol (3, 55 mg, 0.19 mmol) and vinyl butanoate (0.1225 mL, 0.97 mmol) in CH$_2$Cl$_2$ (3 mL), lipase B from Candida antarctica (CALB, 55 mg) was added before the solution was placed in an incubator set to 30 $^\circ$C and 200 rpm. Aliquots of 100 L were collected every 30 min for the first 4 h, then at every 12 h for 3 days, and finally every 24 h for 4 days. The aliquots were analysed by chiral GLC, and no conversion was observed. A new reaction was performed with CALA (60 mg), and aliquots were collected as described above, then analysed by chiral GLC. No conversion was observed.

3.5.3. Kinetic Resolution of 1-(4-Chlorophenyl)prop-2-yn-1-ol (8)

To a solution of 1-(4-chlorophenyl)prop-2-yn-1-ol (8) (20.0 mg, 0.12 mmol), and vinyl butanoate (0.069 mL, 0.60 mmol) in dry n-hexane (3.0 mL), 5 pellets of molecular sieve were added before the mixture was incubated at 40 $^\circ$C and 200 rpm. CALB (22.1 mg) was added to the mixture, and aliquots (0.100 mL) were collected every 30 min for the first 3 h, and finally after 19.5 h. The samples were analysed by chiral GLC: $t_R$ (S)-8 = 12.880 min, $t_R$ (R)-8 = 13.087 min, $R_S = 3.5$. After 2.5 h, (R)-8 was not observed by GLC. The ester (R)-9 was produced in 99% ee.

3.6. Asymmetrisations of Ketones by Ketoreductases

3.6.1. General Procedure

The ketones 1, 2 and 4–7 (2.5–60.8 mg, 0.01–0.16 mmol) were dissolved in DMSO (0.10 mL) and transferred to a solution of ketoreductase 228 (KRED 228), NADPH, glucose-6-phosphate (G6P) and glucose-6-phosphate dehydrogenase (G6P-DH) in pH 7.0 phosphate buffer (0.9 mL). The reactions were incubated at 30 $^\circ$C and 300 rpm for 1–28 days, and monitored by TLC (1:2 n-pentane/EtOAc) every 24 h. After full conversion of the starting material, the mixtures were extracted with EtOAc (4 × 10 mL) and the organic phases were combined, washed with water (2 × 20 mL), dried over MgSO$_4$, and filtered before the organic solvent was removed under reduced pressure. The crude products were either purified by flash chromatography (silica, EtOAc/n-pentane) to afford the pure alcohols, or the crude product was analysed by chiral GLC or chiral HPLC.
3.6.2. Asymmetric Synthesis of (R)-1-(4-Amino-3,5-dichlorophenyl)-2-bromoethan-1-ol, (R)-2a

1-(4-Amino-3,5-dichlorophenyl)-2-bromoethan-1-one (2) (28.6 mg, 0.10 mmol) in DMSO (0.10 mL), KRED 228 (10.4 mg), G6P (77.7 mg), G6P-DH (0.1 mL, 20 U) and NADPH (0.3 mg) in pH 7.0 phosphate buffer (0.90 mL). Reaction time: 4 weeks, (R)-2a was obtained in 93% ee. GLC of rac-2: \( t_R (R) = 25.363 \text{ min}, t_R (S) = 25.636 \text{ min}, R_S = 1.9. \)

3.6.3. Asymmetric Synthesis of (S)-N-(4-Acetyl-phenyl)acetamide, (S)-5a

N-(4-Acetylphenyl)acetamide (5) (20.3 mg, 0.11 mmol) in DMSO (0.10 mL), KRED 228 (7.2 mg), G6P (94.1 mg), G6P-DH (0.1 mL, 20 U) and NADPH (0.3 mg) in pH 7.0 phosphate buffer (0.90 mL) was incubated for 2 weeks. After flash chromatography, (100% EtOAc), (S)-5a was obtained in a 45% isolated yield, (8.8 mg, 0.05 mmol), 96% purity, 73% ee. \( R_S (S) = 0.42 \) (EtOAc). HPLC of rac-5: \( t_R (R) = 84.474 \text{ min}, t_R (S) = 91.765 \text{ min}, R_S = 1.56. \) \( [\alpha]_D^{20} = -0.11 \) (c 0.88, EtOH). \(^1\)H NMR (600 MHz, CD3OD): \( \delta 7.50-7.49 \) (d, 2H, H arom, \(^3\)JHH = 8.4 Hz), 7.31-7.30 (d, 2H, H arom, \(^3\)JHH = 8.4 Hz), 4.80-4.77 (q, 1H, HO-CH, \(^3\)JHH = 6.5 Hz), 2.11 (s, 3H, CO-CH3), 1.42-1.41 (d, 3H, CH-CH3, \(^3\)JHH = 6.5 Hz). \(^13\)C NMR (600 MHz, MeOD): \( \delta 171.6 \) (CO), 143.4 (C), 138.8 (C), 126.9 (CH arom), 121.1 (CH arom), 70.5 (CH), 25.4 (CH3), 23.7 (CH3). MS (TOF-ASAP): [M + H] + 180.1025 m/z.

3.6.4. Asymmetric Synthesis of (S)-N-(2,6-dichloro-4-(1-hydroxyethyl)phenyl)acetamide, (S)-6a

N-(4-Acetyl-2,6-dichlorophenyl)acetamide (6) (32.1 mg, 0.13 mmol) in DMSO (0.10 mL), KRED 228 (8.1 mg), G6P (74.4 mg, 0.286 mmol), G6P-DH (0.1 mL, 20 U) and NADPH (0.2 mg) in phosphate buffer (pH 7.0, 0.90 mL). Reaction time 48 h, flash chromatography (1:2 n-pentane/EtOAc), isolated yield (S)-6a: 31% yield (10.1 mg, 0.04 mmol), 99% purity, >98% ee. GLC of rac-6: \( t_R (S) = 44.46 \text{ min}, t_R (R) = 45.25 \text{ min}, R_S = 2.05. \) (S)-6a \( [\alpha]_D^{20} = -0.21 \) (c 1.01, EtOH). \(^1\)H NMR (600 MHz, MeOD): \( \delta 7.45 \) (s, 2H, H arom), 4.82-4.79 (q, 1H, CH-OH, \(^3\)JHH = 6.5 Hz), 2.17 (s, 3H, CO-CH3), 1.42-1.41 (d, 3H, CH(OH)-CH3, \(^3\)JHH = 6.3 Hz). \(^13\)C NMR (100 MHz MeOD): \( \delta 172.0 \) (CO), 150.0 (C), 135.2 (C), 132.2 (C), 126.5 (CH Ar), 69.4 (CH), 25.4 (CH3), 22.3 (CH3). MS: (ASAP-TOF) [M + H] + 248.0245 m/z.

3.6.5. Asymmetric Synthesis of (R)-N-(4-(2-Bromo-1-hydroxyethyl)phenyl)acetamide, (R)-7a

N-(4-(2-Bromocetyl)phenyl)acetamide (7) (27.1 mg, 0.11 mmol) in DMSO (0.10 mL), KRED 228 (8.7 mg), G6P (82.9 mg, 0.319 mmol), G6P-DH (0.1 mL, 20 U) and NADPH (0.4 mg) in phosphate buffer (pH 7.0, 0.90 mL). Two days reaction time, flash chromatography (100% EtOAc), \( R_S (R) = 0.57, \) isolated yield: 27% (7.3 mg, 0.03 mmol), 98% purity, 35% ee. HPLC of rac-7: \( t_R (R) = 14.037 \text{ min}, t_R (S) = 17.035 \text{ min}, R_S = 2.55. \) \( [\alpha]_D^{20} = +0.07 \) (c 0.73, EtOH). \(^1\)H NMR (600 MHz, CD3OD): \( \delta 7.56-7.55 \) (m, 2H, H arom, \(^3\)JHH = 8.7 Hz), 7.36-7.35 (m, 2H, H arom, \(^3\)JHH = 8.6 Hz), 4.85-4.83 (m, 1H, HO-CH, \(^3\)JHH = 4.6 Hz, \(^3\)JHH = 7.7 Hz), 3.62-3.60 (dd, 1H, CH-Br, \(^3\)JHH = 4.4 Hz, \(^2\)JHH = 10.5 Hz), 3.56-3.53 (dd, 1H, CH-Br, \(^3\)JHH = 7.7 Hz, \(^2\)JHH = 10.5 Hz), 2.13 (s, 3H, CO-CH3). \(^13\)C NMR (600 MHz, CD3OD): \( \delta 170.2, 138.2, 137.6, 126.4, 119.6, 73.1, 37.8, 22.4. \) MS (TOF-ASAP): [M + H] + 258.0130 m/z.

4. Conclusions

Asymmetrisation of ketones 2 and 6 with KRED 228 were the only asymmetrisations in the series of ketones 1, 2, and 4-7 that produced the respective alcohol with high enantiomeric excess, giving (R)-2a in a 93% ee (low yield) and (S)-6a in a 98% ee and 31% yield. (R)-2a may be reacted with t-butylamine, yielding (R)-clenbuterol in high enantiomeric excess. (S)-6a may be a precursor for important enantiopure compounds.

The absolute configuration of the alcohols was determined by comparing elution orders on GLC with similar compounds. KRED 228 from Syncozymes Co., Ltd. was found to be a suitable enzyme for the reduction of substituted arylketones with several substituents on the benzene ring, however when an \( \alpha \)-halogen is present the enzyme is not fully efficient. In addition, protection of the amino group on the benzene ring seems to be crucial.
Kinetic resolutions of the racemic bromo alcohol 3 with CALA and CALB were not successful. The transesterification reactions showed low reactivity and low stereoselectivity with both lipases. Due to the excellent selectivity of the CALB catalysed kinetic resolution of propargyl alcohol 8 with vinyl butanoate in hexane it was anticipated that both the amino and the chloro substituents in meta-positions of 3 cause the problem. Both steric hindrance and electronic effects of these substituents leading to an irreversible substrate-enzyme complex might be the reason for the low conversion of the two lipases.

Author Contributions: Investigation and writing—original draft preparation, F.H.B.; supervision and writing—review and editing, E.E.J.; investigation, M.B.H., S.E., and W.Z.
