Abstract

The article is devoted to solving the fundamental and applied problem of nonlinear structural mechanics of machines by introducing into the drum two additional stop cylinders with supporting rollers at the end and adjustable length, providing a given elliptical or circular shape of a flexible shell with a smoothly variable geometry in the area of its contact with compacted pavement material. Compaction of soil, gravel and asphalt concrete in the sphere of road is not only an integral part of the technological process of the roadbed, road foundation and surface construction, but it is actually the main operation to ensure their strength, stability and durability. The quality, cost and speed of road construction, the possibility of using fundamentally new technologies, structures and materials is largely determined by the availability of modern road machinery.

Keywords
Road roller shell force stress

1. Introduction

One of the main directions of scientific and technological progress is the creation and introduction of new equipment, the improvement of the existing one, as well as the improvement of its quality, reliability, durability with minimal material consumption and cost per unit of power.

A summary of the issue of quantifying the carrying capacity of the shell can only be done after joint mathematical modeling of the physical process of interaction between the roller and the material of the sealing coating and solving the problem of local elastic stability of a thin-walled cylindrical shell (shell) under local contact pressure” (Abdeev et al., 2011; Sakimov et al., 2018).

The article presents the analysis of the behavior of the deformable roller shell of the road roller, and the material to be compacted under the compacting roller of the road roller (Dudkin et al., 2006), in which the rigid circular shell of the roller is replaced by a forcefully deformable elliptical shape, which, unlike the circular design, allows variation, adjustment and optimization of the impact of the road roller on the material to be compacted.

2. Mathematical Model

This article is devoted to solving this fundamental and applied problem of nonlinear structural mechanics of machines (Birger et al., 1979) by introducing into the drum two additional stop cylinders with supporting rollers at the end and adjustable length, providing a given elliptical or circular shape of a flexible shell with a smoothly variable geometry (Dudkin et al, 2006; Abdeev et al., 2012et al., 2018) in the area of its contact with compacted pavement material, based on:

1) the closest and symmetrical positioning at the same distance $l_r$ of roller support-cylinders, the length of which in the design scheme of figure 1 is almost identical to the width $B$ of the roller (figure 2), and their rigidity, according to size, is much more than deformability of the flexible shell having the thickness $\delta \ll d_p$ - the diameter of the rollers;
2) the distribution locality of contact pressure functions $q_c = q_c(x_1), q_p = q_p(x_1)$, at which the lengths of the corresponding projections $C, C_p$ pologic shell arcs in contact with the material of the coating being...
compacted are comparable to its thickness \( \delta \), and in this connection, as is known (Ponomarev and Andreeva, 1980), in small areas of the simulated thinwalled system bounded by \( 2C \times B \) areas (stationary roller, figure 1) and \( C_p \times B \) (rotating movable roller, figure 1) obvious conditions are observed (Sakimov et al., 2018; Bostanov et al., 2018)

\[
\frac{1}{80} < \frac{\delta}{2C} < \frac{1}{5}, \quad \frac{1}{80} < \frac{\delta}{C_p} < \frac{1}{5}
\]

confirming the low probability of clipping, since within the constraints (1) the shell will deform like a cylindrical flat shell-panel of relatively large thickness \( \delta \) and a small bend (within the limits of size \( \delta \)), in which (Kolkunov, 1972)

\[
y_{\text{max}} < \frac{2l_p}{\gamma}; 0.4l_p
\]

At the same time, in order to guarantee the tuning of the considered structure in order to exclude the possibility of local deformations from the reactive distributed forces \( q_o, q_p \) (n), it is necessary to solve the stability test problem. For its mathematical formulation, with a margin of rigidity and bearing capacity, an idealized model of a linearly elastic homogeneous isotropic rectangular plate-panel with a plan size \( 2l_p \times B \) (Fig. 2) is used with an initial bend \( y_1 = y(x_1) \), approximated by circle or ellipse functions and fixed projections \( I_p \geq C_p \), symmetrically located arcs \( S_p \). At the same time, for the calculated pressure \( q_p(x_1) \) with the greatest extremum \( q_{\text{max}} \) (Fig. 2) the functional expression of Hertz-Shtererman is taken (Sakimov et al., 2018)

\[
q_p = q_p(x_1) = \frac{q}{l_p} \sqrt{l_p^2 - x_1^2} \geq 0, \quad q < q_{\text{kr}}
\]

changing on a plane \(-l_p \leq x_1 \leq l_p, -0.5B \leq z_1 \leq 0.5B\) by the same law as addiction \( q_o = q_o(x_1) \), in the case of a stationary drum (Fig. 1) while limiting the maximum value \( q < q_{\text{kr}} \) regulatory minimum safety factor \([n] = 1.5\) for an ideal original shell surface (no dents)

\[
n = \frac{q_{\text{kr}}}{q_{\text{mp}}} \geq [n] = 1.5
\]

in relation to the upper critical load \( q_{\text{kr}} \), corresponding to the unacceptable phenomenon of flipping the shell to a new stationary equilibrium state with the formation of a local bend (Temirbekov et al., 2019).

Each mechanical system with the loss of stability can behave differently. A transition to a certain new equilibrium state usually takes place, which in the overwhelming majority of cases, is accompanied by large displacements, the appearance of plastic (residual) deformations or complete destruction. In relation to the considered road roller with flexible elastic shell (Dudkin et al., 2006; Abdeevo, 2012), the listed negative factors lead to the impossibility of its further operation or to a significant reduction in the quality indicators of the fulfillment of its functional purpose. On this basis, the topic of this article is extremely relevant, innovative and promising.

The corresponding applied physical and mathematical problem of an elastically deformable solid body is based on the fundamental system of two nonlinear fourth-order differential equations (Fig. 2).

\[
\begin{align*}
\frac{E \cdot \delta^2}{12(1-\mu^2)} \psi'''' &= \frac{\partial^2 \phi}{\partial x_1^2} \frac{\partial^2 \omega}{\partial x_1^2} \frac{\partial^2 \phi}{\partial x_1^2} \frac{\partial^2 \omega}{\partial x_1^2} - \frac{\partial^2 \phi}{\partial x_1 \partial z_1} \left( \frac{\partial^2 \omega}{\partial x_1 \partial x_1} + \frac{\partial^2 \omega}{\partial x_1 \partial z_1} \right) \left( \frac{\partial^2 \omega}{\partial x_1 \partial z_1} - \frac{\partial^2 \omega}{\partial x_1 \partial x_1} \right) \\
-2 \frac{\partial^2 \phi}{\partial x_1 \partial z_1} \left( \frac{\partial^2 \omega}{\partial x_1 \partial x_1} + \frac{\partial^2 \omega}{\partial x_1 \partial z_1} \right) &+ \frac{q}{\delta} \frac{l_p^2}{l_p^2 - x_1^2} \\
\frac{1}{E} \psi'''' &= \left( \frac{\partial^2 \omega}{\partial x_1 \partial z_1} \right)^2 - \frac{\partial^2 \omega}{\partial x_1 \partial x_1} \frac{\partial^2 \omega}{\partial x_1 \partial z_1} \frac{\partial^2 \omega}{\partial x_1 \partial z_1} \frac{\partial^2 \omega}{\partial x_1 \partial x_1} \frac{\partial^2 \omega}{\partial x_1 \partial z_1};
\end{align*}
\]

where \( E, \mu \) – respectively, the modulus of elasticity and Poisson’s ratio of the shell material (structural spring steel (Abdeevo, 2012));

\[
x_{1j}, z_1 \rightarrow \text{local coordinates of an arbitrary point of the median surface of the shell, varying within}
\]

\[
-l_p \leq x_1 \leq l_p, C_p \geq C = \max > C_p, -0.5B \leq z_1 \leq 0.5B;
\]

Fig. 1. Design and design diagram of a general form with contact pressure diagrams \( q \) and \( q_p \)
\[ \nabla^4 = \nabla^4(x_1, z_1) \quad \text{– double Laplace operator (Kolkunov, 1972; Ponomarev and Andreeva, 1980).} \]

\[ \nabla^4 = \frac{\partial^4}{\partial x_1^4} + 2 \frac{\partial^2}{\partial x_1^2 \partial z_1^2} + \frac{\partial^2}{\partial z_1^4} \]  

In relation to the roller circular shape with a radius of the middle surface \( R_c = \text{const} \) should, in the above relations (10) - (12), make a replacement \( a = b = R_c \), as a module \( \xi = 0 \), according to (12).

In the reserve of local deformability of the shell and in order to simplify the integration of system (5), (6), due to the design features of the design schemes of figures 1 and 2, it is followed by the description of the final state of the element of the shallow shell (Figure 2) by the mechanical-mathematical model of the cylindrical bend of a rectangular plate with the initial curvature \( y_1 \) (10) (Kolkunov, 1972. Ponomarev and Andreeva, 1980), when the desired functions \( \omega(x_1, z_1) \) and \( F(x_1, z_1) \), take the form:

\[ \omega = \omega(x_1), F = F(x_1) = A \cdot \frac{x_1^2}{x_1^2}, \]  

and the stresses (13) in the middle surface become equal

\[ \sigma_{x_1} = \frac{\partial^2 \omega}{\partial x_1^2} = A = \text{const}, \quad \sigma_{z_1} = \tau = 0 \]  

under the assumption that the internal force components \( \sigma_{x_1} \) is considered positive under compression. In this case, the equilibrium condition (5) is transformed into an ordinary differential equation

\[ \frac{E \cdot \delta^2}{12(1-\mu^2)} \cdot \frac{\partial^4 \omega}{\partial x_1^4} + \frac{A}{E} \frac{\partial^4 \omega}{\partial x_1^2 \partial z_1^2} + \frac{q}{\nu \cdot \delta} \sqrt{I_1^2 - x_1^2}, \]  

and relation (6) is identically satisfied \( \equiv 0 \).

It is necessary to supplement dependence (17) by Hooke’s law for constant linear relative deformation (Doudkin et al., 2013)

\[ \varepsilon_{x_1} = \frac{\sigma_{x_1}}{E} - \frac{A}{E} = \text{const} \]  

and geometrically nonlinear Cauchy formula (Kolkunov, 1972):

\[ \varepsilon_{x_1} = \frac{du}{dx_1} + \frac{1}{2} \left( \frac{du}{dx_1} \right)^2 = \frac{A}{E}, \]  

where \( u = u(x_1) \) – displacement function in the direction of the coordinate axis \( x_1 \) (Fig. 3).

The equation (17) is integrated approximately using the Bubnov-Galerkin method of sufficiently effective and accurate variational analytical method (Doudkin et al., 2018; Doudkin et al., 2019). The function \( \omega(x_1) \) is approximated by a polynomial of the fourth degree (Kolkunov, 1972. Ponomarev and Andreeva, 1980).

\[ \omega = \omega(x_1) = f \left( 1 - \frac{x_1^2}{I_1^2} \right)^2 = f \left( 1 - \frac{2x_1^2}{I_1^2} + \frac{x_1^4}{I_1^4} \right), \]  

satisfying the boundary conditions of Figure 3:
\( \omega(\pm l_p) = 0 \), \( \frac{da}{dx_1} \bigg|_{x_1=\pm l_p} = f \left( -\frac{4z_1}{y} \pm \frac{x_1^2}{y^2} \right) \bigg|_{x_1=\pm l_p} = 0 \), \( (21) \)

where the maximum calculated chord length \( l_p \), identical to the distance between roller bearings (Fig. 1), is found, according to (8) and guided by (Sakimov and Eleukenov, 2012; Sakimov et al., 2018).

\[ l_p \geq C = \max \left( 1.0925 a_p \cdot \frac{G_u}{E_k \cdot b_p \cdot B} \right) = 1.0925 \cdot 0.9 R_c \frac{G_u}{E_k \cdot B} = 12.6146 \cdot R_c \frac{G_u}{E_k} \]

(22)

with constructive-permissible dimensions of the semi axes of the ellipse (11) (Abdeev et al., 2012)

\[ a_p = 1.0954 \cdot R_c, b_p = 0.9 \cdot R_c \]

(23)

with extreme eccentricity (12)

\[ \xi = \xi_p = 0.57 \]

(24)

To solve the system (17), (19), the necessary derivatives of the functions \( \omega(x_1), y_1(x_1) \) are preliminarily determined based on dependencies (10), (20), (21) and reference information (Doudkin et al., 2013):

\[ \frac{da}{dx_1} = 4f \left( -\frac{4z_1}{y} + \frac{x_1^2}{y^2} \right) \]

(25)

\[ \frac{d^2w}{dx_1^2} = 4f \left( -\frac{1}{y} + \frac{3x_1^2}{y^2} \right) \]

(26)

\[ \frac{d^4w}{dx_1^4} = 24f \left( \frac{1}{y} \right) \]

(27)

\[ \frac{dy_1}{dx_1} = \frac{b}{2} \left( -\frac{x_1}{y} \right) \approx \frac{bx}{a^2} \]

(28)

The first derivative (25) is substituted into the deformation relation (19) and by direct integration (Doudkin et al., 2013) the second kinematic component is found (Fig. 3):

\[ u = u(x_1) = \int \left[ \frac{A}{E} \cdot \frac{1}{2} \left( \frac{da}{dx_1} \right)^2 \right] \cdot dx_1 + C = \frac{4}{E} x_1 - 8f^2 \left( \frac{x_1^2}{3y} + \frac{x_1^2}{5y} \right) \]

(29)

where is an arbitrary constant \( C = 0 \) from the odd-odd condition \( u(0) = 0 \) function \( u(x_1) \).

To calculate the constant \( A \), the third homogeneous boundary equality was formulated (Kolkunov, 1972):

\[ u(\pm l_p) = \pm \frac{A}{E} l_p - 8f^2 \left( \frac{1}{3y} + \frac{2}{5y} + \frac{1}{7y} \right) = 0, \Rightarrow \]

\[ A = \frac{64E}{105} \cdot \frac{f^2}{l_p^3} \]

Further, the procedure of the Bubnov-Galerkin method is applied to the one-dimensional equation (17) in the form of the corresponding integral-differential relation

\[ 2 \int_0^{l_p} \left[ \frac{E \cdot a^2}{12(1 - \varepsilon^2)} \cdot \left( \frac{d^2u}{dx_1^2} \right)^2 \right] \cdot dx_1 + 64E \cdot f^2 \left( \frac{d^2u}{dx_1^2} \right) \cdot \frac{q}{a} \cdot \left( 1 - \frac{x_1^2}{l_p^2} \right) \times \left( 1 - \frac{x_1^2}{l_p^2} \right)^2 \cdot dx_1 = 0 \]

(31)

taking into account expressions (20), (26) - (28), (30) and the symmetry of the design scheme of Figure 3, and the tables (Doudkin et al., 2013) are used to calculate the integrals included in (31), after a valid simplification of the functional formula \( y_1(x_1) \), subject to the restrictions (10) (Temirbekov et al., 2019) and its derivatives (28):

\[ y_1 = y_1(x_1) = b \left( 1 - \frac{1}{\sqrt{1 - \frac{x_1^2}{a^2}}} \right) \approx b \left( 1 - \frac{1}{\sqrt{1 - \frac{x_1^2}{2a^2}}} \right) \]

(32)

\[ \frac{d^2y_1}{dx_1^2} = \frac{b}{a^2} \]

(33)

\[ \frac{d^2y_1}{dx_1^2} \bigg|_{x_1=0} = 64f \]

(34)
\[ d^2q \over dt^2 \bigg|_{t=0} = 9.0822\lambda - 1.3244\lambda = 0, \quad (43) \]

where it comes from:
\[ \lambda = 0.1458 : \quad \lambda_0 = 1.3244 \cdot \lambda = 0 \quad (44) \]

Realizing condition \( dq^2 \over dt^2 = 0 \), two values are found
\( \zeta_r, \zeta_m \) corresponding to the top \( q_{kr} \) and bottom \( q_{km} \) (after clicking (Kolkunov, 1972)) critical pressure on the shell (Fig. 2):
\[ dq^2 \over dt^2 |_{\zeta=\zeta_r} = 4.5411\zeta^2_n - 1.3244\lambda \cdot \zeta_n + 2.173 \frac{1}{1-\mu^2} = 0 \quad (45) \]
\[ \zeta_n = 0.145825 \cdot \lambda \pm \sqrt{0.02126542 - \frac{0.47852}{1-\mu^2}} \quad (46) \]

Click area border \( \lambda_{gr} \) adequate to the case when the function (42) has an inflection point containing a horizontal tangent, when the root expression in (46) vanishes, \( \Rightarrow \)
\[ \lambda_{gr} = \frac{4.7437}{1-\mu^2} = \text{const}; \quad (47) \]
and, as a consequence of (46),
\[ \zeta_0(g) = \zeta_{gr} = 0.145825 \cdot \lambda_{gr} = 0.69175 \frac{1}{1-\mu^2} = \text{const} \quad (48) \]

Subsequent analytical testing of formulas (22), (42), (44), (46) - (48) are performed in numerical form using specific data given in published papers (Abdeev et al., 2018) for a circular outline of the (K) with \( \zeta = 0 \), \( E(0) = 1.5708 \) and in the case of an elliptical shape (E) of the surface of the drum, when \( \zeta = \xi_p = 0.57 \), \( E(\xi_p) = E(0,57) = 1.4344 \). The material of construction is spring-steel 60C2X (Doudkin et al., 2013) having: \( E = 1.96 \cdot 10^5 \text{MPa} \left( \frac{N}{mm^2} \right) \). Poisson’s ratio \( \mu = 0.256 \) and yield strength \( \sigma_y = 2270 \text{MPa} \left( \frac{N}{mm^2} \right) \). As the linear dimensions of the shell are taken (Fig. 1 and 2) \( \delta = 6.5 \text{mm}, R_x = 600 \text{ mm}, B = 1400 \text{ mm}, l_0 = 90 \text{ mm} \) at rated axle load of the roller \( G_e = 42500 \text{ N} \) and deformation module \( E_k \) sealing coating (Sakimov et al., 2018):
\[ E_k = 8; 20; 30; 65; 116 \text{ MPa} \left( \frac{N}{mm^2} \right) \quad (49) \]

Check the constructive-technological background (22), which regulates a fixed geometric characteristic \( l_p = 90 \text{ mm} \) (Fig. 1-3):
\[ l_p = 90 \text{ mm} > C = 1.26146 \cdot R_c \sqrt{\frac{G_e}{E(k) \cdot B}} = \frac{N}{mm^2} \]
\[ = 1.26146 \cdot 600 \sqrt{\frac{42500}{8-600-1400}} = 60.2 \text{ mm}, \quad (50) \]
when \( E(k) = 8 \frac{N}{mm^2} \), according to (49).
Figure 4 shows the graphs of the functional ratios of the maximum contact pressure \( q_{mp} = q_{mp}(E_k) \) for a rolling roller (Fig. 1), constructed according to the formulas (Sakimov et al., 2018) of figure 1 using dependencies (8), (22), (23) and the quantitative information of Table 1:

- at \( \xi = 0 \), \( E(0) = 1.5708 \) (round drum - "K")
  \[
  q_{mp}^{(c)} = 1.2295 \frac{G_{E_k}}{B \cdot 0.74 \cdot E_k} = 1.2295 \frac{G_{E_k} \cdot E_k \cdot R_c \cdot B}{B \cdot 0.74 \cdot 1.0925 \cdot R_c \cdot E_k} = 1.2295 \frac{G_{E_k} \cdot E_k \cdot R_c \cdot B}{B \cdot 0.74 \cdot 1.0925 \cdot E_k} = 1.5208 \cdot \frac{4250 \cdot E_k}{1400 \cdot 600} = 0.34208 \cdot \sqrt{E_k} \]

- at \( \xi = 0.57 \), \( E(0.57) = 1.434 \) (extreme - elliptical shape of the shell - "E")
  \[
  q_{mp}^{(a)} = 1.2295 \frac{G_{E_k} \cdot E_k \cdot R_c \cdot B}{B \cdot 0.74 \cdot \left( \frac{0.9}{1.0954} \right)^2 \cdot E_k} = 1.9511 \cdot \frac{G_{E_k} \cdot E_k \cdot R_c \cdot B}{B \cdot 0.74 \cdot \sqrt{E_k}} = 1.9511 \cdot \frac{4250 \cdot E_k}{1400 \cdot 600} = 0.43887 \cdot \sqrt{E_k}.
  \]

Table 1 - Numerical data on functions (51), (52)

| Shell Perimeter Shape | \( E_k \) | 0 | 8 | 20 | 60 | 116 |
|-----------------------|----------|---|---|----|----|-----|
| 1 - Circle             | \( q_{mp}^{(c)} \) | 0 | 0.968 | 1.53 | 1.874 | 2.758 | 3.684 |
| 2 - Ellipse            | \( q_{mp}^{(a)} \) | 0 | 1.241 | 1.963 | 2.404 | 3.338 | 4.727 |

**Fig. 4.** Graphic interpretation of the formulas (51), (52)

From equality (48), taking into account (23), (39), (40), (42), (47), we find the boundary thickness \( \delta_{gr} \), as well as maximum deflection \( f_{gr} \) and pressure \( q_{gr} \), to which a click or local loss of stability will occur, accompanied by a change in the shape of the element of the cylindrical shell (Fig. 1 and 2) in the form of a local dent (Fig. 3):

\[
\lambda_{gr} = \frac{b^2 \cdot q_{gr}}{a^2 \cdot \delta_{gr}} = \frac{4.3867 \cdot 10^6}{1.0954 \cdot 400 \cdot 1600} = 4.9072; \quad (53)
\]

\[
\zeta_{gr} = \frac{f_{gr}}{\delta_{gr}} = 0.145825 \cdot \lambda_{gr} = 0.145825 \cdot 4.9072 = 0.7156; \quad (54)
\]

\[
q_{gr} = 1.5137 \cdot \zeta_{gr}^2 - 0.6622 \cdot \lambda_{gr} \cdot \zeta_{gr}^2 = 2.173 \left(1 - (0.256)^2\right) \cdot \zeta_{gr} = 1.5137 \cdot (0.7156)^2 - 0.6622 \cdot 4.9072 \cdot (0.7156)^2 + 2.173 \cdot 0.7156 = 0.4984; \quad (55)
\]

\[
q_{gr}^{(c)} = \frac{q_{gr}}{E} \left( \frac{1}{\delta_{gr}} \right)^4 = 0.4984; \quad (56)
\]

where:

- for round drum with \( a = b = R_c = 600 \ mm\)
  \[
  \delta_{gr}^{(c)} = \frac{b \cdot l_p^2}{4.9072} = \frac{4.9072}{600} = 2.75 \ mm, \quad (57)
  \]

- for an elliptical shell surface
  \[
  \delta_{gr}^{(E)} = \frac{0.9 \cdot R_c \cdot l_p^2}{4.9072 \cdot (1.0954)^2} = \frac{0.9 \cdot 600}{4.9072} = 2.06 \ mm, \quad (60)
  \]

- for round-shaped drum (K)
  \[
  \delta_{gr}^{(E)} = \frac{b \cdot l_p^2}{4.9072} = \frac{4.9072}{600} = 2.75 \ mm, \quad (61)
  \]

- with elliptical shell (E)
  \[
  \delta_{gr}^{(E)} = \frac{b \cdot l_p^2}{4.9072} = \frac{4.9072}{600} = 2.06 \ mm, \quad (62)
  \]

Let us consider in more detail dependencies (39), (40), (42), (44) with the actual thickness of the shell (Abdee et al., 2012) \( \delta = 6.5 \ mm \) > \( \delta_{gr} \), when the phenomenon of clicking is impossible:

- round-shaped drum (K)
- elliptical shell (E)
\[
\lambda_E = \frac{0.9 \cdot R_c \cdot l_0^2}{6.5 \cdot (1,0954^2 \cdot R_c)^2} = 0.9 \cdot 105^2
\]
\[
\zeta_0^{(E)} = 0.1458 \cdot \lambda_E = 0.1458 \cdot 1.559 = 0.2273, \quad (67)
\]
\[
q_{m}^{(E)} = 1.5137 \cdot (0.2273)^3 - 0.6622 \cdot 1.559 \cdot (0.2273)^2 + 2.3254 \cdot 0.2273 = 0.493. \quad (68)
\]

Since, as already noted, at \( \delta = 6.5 \) mm, loss of stability is excluded, the assessment of its bearing capacity is of decisive importance for the normal elastic operation of the shell, (Temirbekov et al., 2019)

\[
\delta_{\text{max}} \leq \sigma_t, \quad (69)
\]

at the highest normal stress and yield strength of the material \( \sigma_t = 2270 \text{ MPa} \left( \frac{N}{mm^2} \right) \) (Abdeev Bet al., 2012). Solving this issue will require a preliminary determination of the operating maximum dimensionless characteristics:

\[
q_m^{(c)}, q_m^{(E)}, \zeta_{\text{max}}, \zeta_{\text{NE}} \text{ при } q_m^{(c)} = 3.684 \cdot \frac{N}{mm^2} = \text{max}
\]

\[
q_m^{(E)} = 4.727 \cdot \frac{N}{mm^2} = \text{max} \text{ (see table 1 and figure 4), based on relations (39), (42), (63), (66):}
\]

\[
q_m^{(c)} = \frac{q_m^{(c)}}{E} \left( \frac{l}{d} \right)^4 = \frac{3.684}{196000} \left( \frac{90}{6.5} \right)^4 = 0.6908, \quad (70)
\]

\[
q_m^{(E)} = \frac{q_m^{(E)}}{E} \left( \frac{l}{d} \right)^4 = \frac{4.727}{196000} \left( \frac{90}{6.5} \right)^4 = 0.8864; \quad (71)
\]

\[
\left\{ 
\begin{array}{l}
1.5137 \cdot \zeta_{\text{max}}^2 - 0.6622 \cdot 2.0769 \cdot \zeta_{\text{NE}}^2 + 2.3254 \cdot \zeta_{\text{NE}} = q_m^{(c)} = 0.6908, \\
1.5137 \cdot \zeta_{\text{max}}^2 - 0.6622 \cdot 1.559 \cdot \zeta_{\text{NE}}^2 + 2.3254 \cdot \zeta_{\text{NE}} = q_m^{(E)} = 0.8864;
\end{array}
\right. \quad (72)
\]

whence by the method of selection or by Cardan’s formulas (Doudkin et al., 2013),

\[
\zeta_{\text{max}} = 0.3398, \quad \zeta_{\text{NE}} = 0.4109, \quad (74)
\]

and the real greatest deflections \( f_c, f_E \) (Fig. 3) will have the following meanings:

\[
f_c = \zeta_{\text{max}} \cdot \delta = 0.3398 \cdot 6.5 = 22.11 \text{ mm}, \quad (75)
\]

\[
f_E = \zeta_{\text{NE}} \cdot \delta = 0.4109 \cdot 6.5 = 26.71 \text{ mm} \quad (76)
\]

Visual illustration of the function (42) approximated by analytic expressions:

\[
q^{(c)} = 1.5137 \zeta^3 - 1.37534 \zeta^2 + 2.3254 \zeta \quad (77)
\]

\[
q^{(E)} = 1.5137 \zeta^3 - 1.03234 \zeta^2 + 2.3254 \zeta \quad (78)
\]

respectively, for circular (K) and ellipsoid (E) shells with \( \delta = 6.5 \) mm presented in figure 5. Dependency graphs \( q^{(c)}(\zeta), \zeta^{(E)}(\zeta) \) constructed according to table 2 and characteristic values (64), (65), (67), (68), (70), (71), (74).

**Table 2.** Numerical information on the functional curves of Figure 5

| Shell Form | \( \zeta \) | 0 | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 |
|------------|------------|----|-----|-----|-----|-----|-----|
| Circle     | \( q^{(c)} \) | 0  | 0.2203 | 0.4222 | 0.6147 | 0.807 | 1.008 |
| Ellipse   | \( q^{(E)} \) | 0  | 0.2237 | 0.4359 | 0.6456 | 0.8619 | 1.094 |

**Fig. 5.** Graphs of dimensionless functional relationships (77) and (78)

### 3. Conclusion

Having absolute extreme deformations (75), (76) – deflections \( f_c, f_E \) it is possible to define:

- local compressive stresses \( \sigma_{\text{c1}}^{(c)}, \sigma_{\text{c1}}^{(E)} \) according to the general formula (16) taking into account (30):

\[
\sigma_{\text{c1}}^{(c)} = \frac{64 \cdot E}{105} \left( \frac{f_c^2}{l_0^2} \right) = \frac{64 \cdot 196000}{105} \left( \frac{2.21}{90} \right)^2 = 72.04 \cdot \frac{N}{mm^2}, \quad (79)
\]

\[
\sigma_{\text{c1}}^{(E)} = \frac{64 \cdot E}{105} \left( \frac{f_E^2}{l_0^2} \right) = \frac{64 \cdot 196000}{105} \left( \frac{2.67}{90} \right)^2 = 105.14 \cdot \frac{N}{mm^2}; \quad (80)
\]

- highest normal stresses \( \sigma_u^{(c)} = \sigma_u^{(c)}(x_1), \sigma_u^{(E)} = \sigma_u^{(E)}(x_1) \) from local cylindrical bend in design sections \( x_1 = 0, x_1 = \pm l_0 = \pm 90 \text{ mm} \) (Fig. 3), applying the different-
tial ratio (Ponomarev et al., 1980; Bostanov et al., 2018) and the second derivative (26) of the function \( \omega(x_1) \):

\[
\sigma_u = \sigma_u(x_1) = - \frac{E \cdot \delta}{2(1 - \mu^2)} \frac{d^2 \omega}{dx_1^2},
\]

(81)

\[
\sigma_u^{(0)}(0) = - \frac{E \cdot \delta}{2(1 - \mu^2)} \left( \frac{4f_k}{l_f^2} \right) = 2 \cdot \frac{E \cdot \delta \cdot f_k}{(1 - \mu^2)l_f^2} =
\]

\[
= 2 \cdot 19600 \cdot 6.5 \cdot 2.21 \cdot \frac{1}{1 - (0.256)^2} = \frac{744}{90^2} N \text{mm}^2.
\]

(82)

\[
\sigma_u^{(E)}(0) = \frac{2 \cdot E \cdot \delta \cdot f_k}{(1 - \mu^2)l_f^2} \left( \frac{1 - (0.256)^2}{0.256} \right) = \frac{708}{90^2} N \text{mm}^2.
\]

(83)

\[\sigma_u^{(k)}(\pm l_p) = -2 \sigma_u^{(0)}(0) = -2 \cdot \frac{744}{90^2} = -1488 \text{ Nmm}^2.\]

(84)

\[
\sigma_u^{(x)}(\pm l_p) = -2 \sigma_u^{(x)}(0) = -2 \cdot \frac{744}{90^2} = -1797.6 \text{ Nmm}^2.
\]

(85)

- common bending static stresses \( \sigma_{oi}^{(x)}(x_1), \sigma_{ei}^{(E)}(x_1) \) from shell deformation in case \( P \geq 0 \) (figure 1) (Dudkin et al., 2012)

\[
\sigma_{oi}^{(E)}(0) = \sigma_{oi}^{(x)}(\pm l_p) = 0
\]

(86)

\[
\sigma_{oi}^{(x)}(0) = \sigma_{oi}^{(x)}(\pm l_p) = 0.
\]

(87)

\[
\sigma_{ei}^{(0)}(0) = \sigma_{ei}^{(x)}(\pm l_p) = 0
\]

(88)

\[
\sigma_{ei}^{(x)}(0) = \sigma_{ei}^{(x)}(\pm l_p) = 0
\]

(89)

Using the results of calculations (79), (80), (82) - (86), (88), (89), condition (69) is checked by neglecting the stress \( \sigma_N \) in the middle surface of the shell from \( P > 0 \) (Fig. 1), compared with the bending components, which are much more orders of magnitude \( \sigma_N \) as proved in article (Abdeevo et al., 2012):

- for the material in section \( x_1 = 0 \) (Fig. 2 and 3)

\[
\sigma_{max}^{(c)}(0) = \sigma_{x_1}^{(c)} + \sigma_{u}^{(c)}(0) + \sigma_{oi}^{(c)}(0) = 72.04 + 744 + 0
\]

\[
= 816.04 \text{ Nmm}^2.
\]

(90)

\[
\sigma_{max}^{(E)}(0) = \sigma_{x_1}^{(E)} + \sigma_{u}^{(E)}(0) + \sigma_{oi}^{(E)}(0) =
\]

\[
= 105.14 + 898.8 + 283.8 = 1207.74 \text{ Nmm}^2.
\]

(91)

- for sections \( x_1 = \pm l_p = 90 \text{ mm} \) (Figures 2, 3)

\[
\sigma_{max}^{(c)}(\pm l_p) = \sigma_{x_1}^{(c)} + \left[ \sigma_{u}^{(c)}(\pm l_p) + \sigma_{oi}^{(c)}(\pm l_p) \right] =
\]

\[
= 72.04 + 1488 + 0 = 1560.04 \text{ Nmm}^2.
\]

(92)

\[
\sigma_{max}^{(E)}(\pm l_p) = \sigma_{x_1}^{(E)} + \left[ \sigma_{u}^{(E)}(\pm l_p) + \sigma_{oi}^{(E)}(\pm l_p) \right] =
\]

\[
= 105.14 + | -1797.6 + 276 | = 1626.74 \text{ Nmm}^2.
\]

(93)

Thus,

\[
\sigma_{omax}^{(c)} = \sigma_{max}^{(c)}(\pm l_p) = 1560.04 \text{ Nmm}^2 < \sigma_{omax}^{(E)} = 1626.74 \text{ Nmm}^2
\]

(94)

and the required elastic operation of this shell without unacceptable residual deformations is ensured with a large minimum margin reaching 28.3%, primarily due to the use of structural spring steel 60Cr2X (Abdeevo et al., 2012) with a high yield strength \( \sigma_Y = 2270 \text{ MPa} \) (Dudkin et al., 2013).

摘要
本文致力于解决机器非线性结构力学的基本问题和应用问题，将两个附加的止动缸末端和可调长度引入到滚筒中，提供给定的椭圆形或圆形形状的柔性壳体，使其平滑在与压实路面材料接触的区域内的可变几何形状。

路面土壤，砾石和沥青混凝土的压实不仅是路基，路基和地面施工技术过程中不可或缺的一部分，而且实际上是确保其强度，稳定性和耐久性的主要操作。道路建设的质量，成本和速度，使用基本新技术，结构和材料的可能性在很大程度上取决于现代道路机械的可用性。
