We develop a method for evaluation of A. Einstein’s strength of systems of partial differential and difference equations based on the computation of Hilbert-type dimension polynomials of the associated differential and difference field extensions. Also we present algorithms for such computations, which are based on the Gröbner basis method adjusted for the modules over rings of differential, difference and inversive difference operators. The developed technique is applied to some fundamental systems of PDEs of mathematical physics such as the diffusion equation, Maxwell equations and equations for an electromagnetic field given by its potential. In each of these cases we determine the strength of the original system of PDEs and the strength of the corresponding systems of partial difference equations obtained by forward and symmetric difference schemes. In particular, we obtain a method for comparing two difference schemes from the point of view of their strength.

Computation of the Strength

I. INTRODUCTION

The concept of the strength of a system of partial differential equations (PDEs) was introduced by A. Einstein as a measure for the size of the solution space of such a system. In\(^6\) A. Einstein defined the strength of a system of partial differential equations governing a physical field as follows: "...the system of equations is to be chosen so that the field quantities are determined as strongly as possible. In order to apply this principle, we propose a method which gives a measure of strength of an equation system. We expand the field variables, in the neighborhood of a point \( P \), into a Taylor series (which presupposes the analytic character of the field); the coefficients of these series, which are the derivatives of the field variables at \( P \), fall into sets according to the degree of differentiation. In every such degree there appear, for the first time, a set of coefficients which would be free for arbitrary choice if it were not that the field must satisfy a system of differential equations. Through this system of differential equations (and its derivatives with respect to the coordinates) the number of coefficients is restricted, so that in each degree a smaller number of coefficients is left free for arbitrary choice. The set of numbers of 'free' coefficients for all degrees of differentiation is then a measure of the 'weakness' of the system of equations, and through this, also of its 'strength'."

Calculating by hand A. Einstein found out, that, for example, the potential and field formulations of Maxwell equations have different strengths for the dimension four. However, he did not obtain the exact expression of the above-mentioned number of free coefficients as a function of the degree of differentiation. Even though there were a number of works on the strength of a system of differential equations (in particular, on its relation to Cartan characters), see, for example,\(^{20-22,25-28}\), and\(^{30}\), there was no method of evaluating such a function until 1980 when A. Mikhalev and E. Pankratev\(^{23}\) showed that the strength of a system of algebraic partial differential equations (that is, a system of the form \( f_i = 0, \ i \in I \), where \( f_i \) are multivariate polynomials in unknown functions and their partial derivatives) is expressed by Kolchin's differential dimension polynomial associated with the differential field extension defined by the system. This observation allowed A. Mikhalev and E. Pankratev to develop two methods of determining the strength of a system of algebraic PDEs via computing the differential dimension polynomial of the corresponding differential field extension. The first method is based on construction of a characteristic set of the
Computation of the Strength

ideal of differential polynomials defined by the system and then computing the differential
dimension polynomial using the leading terms of the elements of the characteristic set (the
idea of this approach comes from the original proof of Kolchin’s theorem, see\textsuperscript{9} (Chapter II,
Theorem 6)). The second approach is based on the works by J. Johnson\textsuperscript{7,8}, who showed that
the differential dimension polynomial of a differential field extension can be computed as a
Hilbert polynomial of the associated module of Kähler differentials. Using free resolutions
for such a module, A. Mikhalev and E. Pankratev\textsuperscript{23} evaluated the strength of several well-
known systems of PDEs including the wave equation, both forms of Maxwell equations,
Dirac equations (with zero mass), Lame equations, and some other systems of PDEs of
mathematical physics. Note that A. Einstein, K. Mariwalla, M. Sue and some other authors
who investigated the concept of strength in 1970s characterized the strength of a system by
the ”coefficient of freedom”, an integer, that is fully determined by the leading coefficient
of the differential dimension polynomial. The fact that such a polynomial provides a far
more precise description of the strength than its leading term was justified by the result
of W. Sit\textsuperscript{29} who proved that the set of differential dimension polynomials is well-ordered
with respect to the natural order \((f(t) < g(t))\) if and only if \(f(r) < g(r)\) for all sufficiently
large integers \(r\); this result allows one to distinguish two systems of PDEs with the same
”coefficient of freedom” by their strength.

Since 1980s the technique of dimension polynomials has been extended to the analysis
of systems of algebraic difference and difference-differential equations. In a series of
works whose results are summarized in\textsuperscript{18} the second author proved the existence and de-
veloped some methods of computation of dimension polynomials of difference field extensions
and systems of algebraic difference equations. These polynomials determine A. Einstein’s
strength of a system of algebraic partial difference equations (we give the details in Section
3 of this work) and, in particular, allow one to evaluate the quality of difference schemes for
PDEs from the point of view of their strength.

The next step in the analysis of systems of PDEs and systems of partial difference equa-
tions is to consider their degrees of freedom with respect to different groups of basic operators
(differentiations or translations). Theorems on multivariate dimension polynomials proved
in\textsuperscript{15–17} (see also\textsuperscript{18} (Chapters 3, 4, 7)) allow to characterize the strength of a system of par-
tial differential, difference or difference-differential equations in the case when the ”weights”
of basic operators of different groups are different. Methods of computations of multivari-
Computation of the Strength

te dimension polynomials for systems of differential, difference and difference-differential equations were developed in\textsuperscript{4,5,15–18,31}, and\textsuperscript{32} with the use of generalizations of the Gröbner basis technique. In particular, the first author has implemented in Maple two algorithms of computation of bivariate difference-differential dimension polynomials via relative Gröbner bases introduced in\textsuperscript{31}.

In this paper we present the theory and technique of differential, difference, and difference-differential dimension polynomials together with the applications of this technique to the analysis of fundamental systems of PDEs of mathematical physics and corresponding systems of partial difference equations. In particular, we develop a method that allows one to compute the strength of such systems in the sense of A. Einstein and compare different difference schemes for a given system of PDEs by their strength. We illustrate this method with the computation of the strength of the diffusion equation, Maxwell equations and equations for an electromagnetic field given by its potential, as well as with the computation of the strength of systems of difference equations obtained from these PDEs via different difference schemes.

II. PRELIMINARIES

In this section we present some basic concepts and results that are used throughout the paper. In what follows, $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{Q}$, and $\mathbb{R}$ denote the sets of all non-negative integers, integers, rational numbers, and real numbers, respectively. The number of elements of a set $A$ is denoted by $|A|$. As usual, $\mathbb{Q}[t]$ denotes the ring of polynomials in one variable $t$ with rational coefficients. By a ring we always mean an associative ring with unit element. Every ring homomorphism is unitary (maps unit element onto unit element), every subring of a ring contains the unit element of the ring. Unless otherwise indicated, by a module over a ring $R$ we always mean a unitary left $R$-module.

2.1. Differential and difference rings and fields

A \textit{differential ring} (respectively, a \textit{difference ring}) is a commutative ring $R$ together with a finite set $\Delta = \{\delta_1, \ldots, \delta_m\}$ of mutually commuting mappings of $R$ into itself such that each $\delta_i$ is a derivation of $R$ (respectively, $\delta_i$ are injective endomorphisms of $R$ also called \textit{translations}). The set $\Delta$ is said to be the \textit{basic set} of the differential (or difference) ring $R$, which is also called a $\Delta$-\textit{ring}. If a $\Delta$-ring is a field, it is called a $\Delta$-\textit{field} (this is a differential
Computation of the Strength

field if ∆ is a set of mutually commuting derivations and a difference field if the elements of ∆ are endomorphisms). If δ₁, ..., δₘ are automorphisms of a difference ring R, we say that R is an inverse difference ring with the basic set ∆. In this case we denote the set \{δ₁, ..., δₘ, δ⁻¹₁, ..., δ⁻¹ₘ\} by ∆* and call R a ∆*-ring (if R is a field, it is called an inverse difference field or a ∆*-field).

Let R be a ∆-ring and R₀ a subring (ideal) of R such that δ(R₀) ⊆ R₀ for any δ ∈ ∆. Then R₀ is called a ∆-subring (respectively, a ∆-ideal) of R. If R₀ is a ∆-subring of R, we also say that R is a ∆-ring extension of R₀.

If the elements of ∆ act on R as mutually commuting derivations, we say that R₀ is a differential subring (differential ideal) of R; if the elements of ∆ are mutually commuting injective endomorphisms, we say that R₀ is a difference subring (difference ideal) of R. Anyway, the prefix ∆-, depending on the context, means either ”differential” or ”difference”, while the prefix ∆*- means ”inversive difference”. If R is a ∆*-ring (this assumption implies that ∆ is a set of mutually commuting automorphisms of R), then a subring (ideal) R₀ of R is called a ∆*-subring (respectively, ∆*-ideal) of R if α(R₀) ⊆ R₀ for any α ∈ ∆*. (Δ*-ideals are also called reflexive difference ideals of R; this term, as well as the term ∆*-ideal, is also used for ideals I of a difference ∆-ring R such that for any δ ∈ ∆, a ∈ R, the inclusion δ(a) ∈ I implies a ∈ I). If R is a ∆- (or ∆*- ) field and R₀ a subfield of R which is also a ∆- (respectively, ∆*- ) subring of R, then R₀ is said to be a ∆- (respectively, ∆*- ) subfield of R while R is called a ∆- (respectively, ∆*- ) field extension (or overfield) of R₀. In this case we also say that we have a ∆-(or ∆*- ) field extension R/R₀.

If R is a ∆-ring with a basic set ∆ = \{δ₁, ..., δₘ\}, then Θ∆ (or Θ if the set ∆ is fixed) will denote the free commutative monoid generated by δ₁, ..., δₘ. Elements of Θ will be written in the multiplicative form δ₁ᵏ₁ ... δₘᵏₘ (k₁, ..., kₘ ∈ N) and considered as the corresponding mappings of R into itself. If R is an inverse difference (∆*- ) ring, then Γ∆ (or Γ if the set ∆ is fixed) will denote the free commutative group generated by the set ∆. It is clear that elements of the group Γ (written in the multiplicative form δ₁ⁱ₁ ... δₘⁱₘ where i₁, ..., iₘ ∈ Z) act on R as automorphisms and Θ is a subsemigroup of Γ.

Let R be a ∆-ring and S ⊆ R. Then the intersection of all ∆-ideals of R containing S is denoted by [S]. Clearly, [S] is the smallest ∆-ideal of R containing S; as an ideal, it is generated by the set ΘS = \{θ(a) | θ ∈ Θ, a ∈ S\}. If J = [S], we say that the ∆-ideal J is generated by the set S called a set of ∆-generators of J. If S is finite, S = \{a₁, ..., aₖ\}, we
Computation of the Strength

write \( J = [a_1, \ldots, a_k] \) and say that \( J \) is a \textit{finitely generated \( \Delta \)-ideal} of the \( \Delta \)-ring \( R \). (In this case elements \( a_1, \ldots, a_k \) are said to be \( \Delta \)-\textit{generators} of \( J \).) If \( R \) is an inversive difference (\( \Delta^* \)) ring and \( S \subseteq R \), then the smallest \( \Delta^* \)-ideal of \( R \) containing \( S \) is denoted by \([S]^*\) (as an ideal, it is generated by the set \( \Gamma S = \{\gamma(a) | \gamma \in \Gamma, a \in S\} \). If \( S \) is finite, \( S = \{a_1, \ldots, a_k\} \), we write \([a_1, \ldots, a_k]^*\) for \( I = [S]^* \) and say that \( I \) is a \textit{finitely generated \( \Delta^* \)-ideal} of \( R \); in this case the elements \( a_1, \ldots, a_k \) are called \( \Delta^* \)-generators of \( I \).

Let \( R \) be a \( \Delta \)-ring, \( R_0 \) a \( \Delta \)-subring of \( R \) and \( B \subseteq R \). The intersection of all \( \Delta \)-subrings of \( R \) containing \( R_0 \) and \( B \) is called the \( \Delta \)-\textit{subring} of \( R \) \textit{generated by the set} \( B \) \textit{over} \( R_0 \); it is denoted by \( R_0 \langle B \rangle \). (As a ring, \( R_0 \langle B \rangle \) coincides with the ring \( R_0[\{\theta(b) | b \in B, \theta \in \Theta\}] \) obtained by adjoining the set \( \{\theta(b) | b \in B, \theta \in \Theta\} \) to the ring \( R_0 \).) The set \( B \) is said to be the set of \( \Delta \)-\textit{generators} of the \( \Delta \)-ring \( R_0 \langle B \rangle \) over \( R_0 \). If this set is finite, \( B = \{b_1, \ldots, b_k\} \), we say that \( R' = R_0 \langle B \rangle \) is a \textit{finitely generated \( \Delta \)-ring extension} (or \( \Delta \)-ring extension) of \( R_0 \) and write \( R' = R_0 \langle b_1, \ldots, b_k \rangle \). If \( R \) is a \( \Delta \)-field, \( R_0 \) a \( \Delta \)-subfield of \( R \) and \( B \subseteq R \), then the intersection of all \( \Delta \)-subfields of \( R \) containing \( R_0 \) and \( B \) is denoted by \( R_0 \langle B \rangle \) (or \( R_0 \langle b_1, \ldots, b_k \rangle \) if \( B = \{b_1, \ldots, b_k\} \) is a finite set). This is the smallest \( \Delta \)-subfield of \( R \) containing \( R_0 \) and \( B \); it coincides with the field \( R_0(\{\theta(b) | b \in B, \theta \in \Theta\}) \). The set \( B \) is called a set of \( \Delta \)-\textit{generators} of the \( \Delta \)-field \( R_0 \langle B \rangle \) over \( R_0 \). If \( R \) is an inversive difference (\( \Delta^* \)) ring, \( R_0 \) a \( \Delta^* \)-subring of \( R \) and \( B \subseteq R \). Then the intersection of all \( \Delta^* \)-subrings of \( R \) containing \( R_0 \) and \( B \) is the smallest \( \Delta^* \)-subring of \( R \) containing \( R_0 \) and \( B \). This ring coincides with the ring \( R_0[\{\gamma(b) | b \in B, \gamma \in \Gamma\}] \); it is denoted by \( R_0 \langle B \rangle^* \). The set \( B \) is said to be a \textit{set of \( \Delta^* \)-generators} of \( R_0 \langle B \rangle^* \) over \( R_0 \). If \( B = \{b_1, \ldots, b_k\} \) is a finite set, we say that \( S = R_0 \langle B \rangle^* \) is a \textit{finitely generated \( \Delta^* \)-ring extension} (or \( \Delta^* \)-\textit{overring}) of \( R_0 \) and write \( S = R_0 \langle b_1, \ldots, b_k \rangle^* \). If \( R \) is a \( \Delta^* \)-field, \( R_0 \) a \( \Delta^* \)-subfield of \( R \) and \( B \subseteq R \), then the intersection of all \( \Delta^* \)-subfields of \( R \) containing \( R_0 \) and \( B \) is denoted by \( R_0 \langle B \rangle^* \). This field coincides with the field \( R_0(\{\gamma(b) | b \in B, \gamma \in \Gamma\}) \). The set \( B \) is called a \textit{set of \( \Delta^* \)-generators} of the \( \Delta^* \)-field extension \( R_0 \langle B \rangle^* \) of \( R_0 \). If \( B \) is finite, \( B = \{b_1, \ldots, b_k\} \), we write \( R_0 \langle b_1, \ldots, b_k \rangle^* \) for \( R_0 \langle B \rangle^* \).

In what follows we often consider two or more \( \Delta \)- (or \( \Delta^* \)) rings \( R_1, \ldots, R_p \) with the same basic set \( \Delta = \{\delta_1, \ldots, \delta_m\} \). Formally speaking, it means that for every \( i = 1, \ldots, p \), there is some fixed mapping \( \nu_i \) from the set \( \Delta \) into the set of all derivations or injective endomorphisms of the ring \( R_i \) such that any two mappings \( \nu_i(\delta_j) \) and \( \nu_i(\delta_k) \) of \( R_i \) commute (\( 1 \leq j, k \leq n \)). We shall identify elements \( \delta_j \) with their images \( \nu_i(\delta_j) \) and say that elements
Computation of the Strength

of the set $\Delta$ act as mutually commuting derivations or injective endomorphisms of the ring $R_i \ (i = 1, \ldots, p)$.

Let $R_1$ and $R_2$ be differential or difference or inversive difference rings with the same basic set $\Delta$. A ring homomorphism $\phi : R_1 \to R_2$ is called a $\Delta$-homomorphism if $\phi(\delta(a)) = \delta(\phi(a))$ for any $\delta \in \Delta, a \in R_1$. (Clearly, if $\phi : R_1 \to R_2$ is a $\Delta$-homomorphism of $\Delta^*$-rings, then $\phi(\delta(a)) = \delta(\phi(a))$ for any $\delta \in \Delta^*, a \in R_1$.) If $R_1$ and $R_2$ are two $\Delta$-overrings of the same $\Delta$-ring $R_0$ and $\phi : R_1 \to R_2$ is a $\Delta$-homomorphism such that $\phi(a) = a$ for any $a \in R_0$, we say that $\phi$ is a $\Delta$-homomorphism over $R_0$ or that $\phi$ leaves the ring $R_0$ fixed. It is easy to see that the kernel of any $\Delta$-homomorphism of $\Delta$-rings $\phi : R \to R'$ is a $\Delta$-ideal of $R$ (moreover, in the case of difference rings, this kernel is a reflexive difference ideal of $R_1$). Conversely, let $g$ be a surjective homomorphism of a $\Delta$-ring $R$ onto a ring $S$ such that $\text{Ker} \ g$ is a $\Delta$- or $\Delta^*$- (if $R$ is a difference $\Delta$-ring) ideal of $R$. Then there is a unique structure of a $\Delta$-ring on $S$ such that $g$ is a $\Delta$-homomorphism. In particular, if $I$ is a $\Delta$- or $\Delta^*$- (if $R$ is a difference $\Delta$-ring) ideal of a $\Delta$-ring $R$, then the factor ring $R/I$ has a unique structure of a $\Delta$-ring such that the canonical surjection $R \to R/I$ is a $\Delta$-homomorphism. In this case $R/I$ is said to be the $\Delta$-factor ring of $R$ by $I$.

If a $\Delta$- (or $\Delta^*$-) ring $R$ is an integral domain, then its quotient field $Q(R)$ can be naturally considered as a $\Delta$- (respectively, $\Delta^*$-) overring of $R$. (If $\Delta$ consists of derivations, then they extend to $Q(R)$ via the quotient rule). In this case $Q(R)$ is said to be the quotient $\Delta$- (respectively, $\Delta^*$-) field of $R$. Clearly, if a $\Delta$- (or $\Delta^*$-) field $K$ contains an integral domain $R$ as a $\Delta$- (respectively, $\Delta^*$-) subring, then $K$ contains the quotient $\Delta$- (respectively, $\Delta^*$-) field $Q(R)$.

2.2. Differential, difference, and inversive difference polynomials. Algebraic differential and difference equations.

With the above notation, let $R$ be a $\Delta$- (or $\Delta^*$-) ring and let $U = \{u_\lambda | \lambda \in \Lambda\}$ be a family of elements in some $\Delta$- (respectively, $\Delta^*$-) ring extension of $R$. We say that the family $U$ is $\Delta$-algebraically dependent over $R$, if the family $\Theta U = \{\theta(u_\lambda) | \theta \in \Theta, \lambda \in \Lambda\}$ is algebraically dependent over $R$ (that is, there exist elements $v_1, \ldots, v_k \in \Theta U$ and a non-zero polynomial $f(X_1, \ldots, X_k)$ with coefficients in $R$ such that $f(v_1, \ldots, v_k) = 0$). Otherwise, the family $U$ is said to be $\Delta$-algebraically independent over $R$ or a family of $\Delta$-indeterminates over $R$. In the last case, the $\Delta$-ring $S = R\{(u_\lambda)_{\lambda \in \Lambda}\}$ is called the algebra of $\Delta$-polynomials over $R$. If $\Delta$
consists of derivations (respectively, injective endomorphisms), then $S$ is also called a ring of differential (respectively, difference) polynomials in the difference (or $\sigma$-) indeterminates $\{(u_\lambda)_{\lambda \in \Lambda}\}$ over $R$. If $R$ is a $\Delta^*$-ring and the family $U$ considered above is $\Delta$-algebraically independent over $R$, then the ring $R\{(u_\lambda)_{\lambda \in \Lambda}\}^*$ is called the algebra of $\Delta^*$-polynomials in the $\Delta^*$-indeterminates $u_\lambda$ over $R$.

If a family consisting of one element $u$ is $\Delta$-algebraically dependent over $R$, the element $u$ is said to be $\Delta$-algebraic over $R$. If the set $\{\theta(u)|\theta \in \Theta\}$ is algebraically independent over $R$, we say that $u$ is $\Delta$-transcendental over the ring $R$.

Let $R$ be a $\Delta$-field, $L$ a $\Delta$-field extension of $R$, and $A \subseteq L$. We say that the set $A$ is $\Delta$-algebraic over $R$ if every element $a \in A$ is $\Delta$-algebraic over $R$. If every element of $L$ is $\Delta$-algebraic over $R$, we say that $L$ is a $\Delta$-algebraic field extension of $R$.

The following statement is proved in (Chapter 1, Section 6), (Chapter 2, Theorem I), and (Propositions 3.3.7, 3.4.4) for differential, difference and inversive difference rings.

**Proposition II.1.** Let $R$ be a $\Delta$- (respectively, $\Delta^*$-) ring and $I$ an arbitrary set. Then there exists an algebra of $\Delta$- (respectively, $\Delta^*$-) polynomials over $R$ in a family of $\Delta$- (respectively, $\Delta^*$-) indeterminates with indices from the set $I$. If $S$ and $S'$ are two such algebras, then there exists a $\Delta$-isomorphism $S \to S'$ that leaves the ring $R$ fixed. If $R$ is an integral domain, then any algebra of $\Delta$- (respectively, $\Delta^*$-) polynomials over $R$ is an integral domain.

The algebra of $\Delta$-polynomials over a $\Delta$-ring $R$ in a family of $\Delta$-indeterminates with indices from a set $I$ is a polynomial $R$-algebra in the set of indeterminates $\Theta Y = \{y_{i,\theta}\}_{i \in I, \theta \in \Theta}$ with indices from the set $I \times \Theta$. This algebra, as it is shown in (Chapter 2, Theorem I), and (Propositions 3.3.7) can be viewed as a $\Delta$-ring extension of $R$ where $\delta(y_{i,\theta}) = y_{i,\delta \theta}$ for any $\delta \in \Delta$, $y_{i,\theta} \in \Theta Y$. Setting $y_{i} = y_{i,1}$ we can write $y_{i,\theta}$ as $\theta y_{i}$. If $R$ is a $\Delta^*$-ring, then the algebra of $\Delta^*$-polynomials over $R$ in $\Delta$-indeterminates with indices from a set $I$ is a polynomial $R$-algebra $S$ in the set of indeterminates $\Gamma Y = \{y_{i,\gamma}\}_{i \in I, \gamma \in \Gamma}$ with indices from the set $I \times \Gamma$. As it is shown in (Propositions 3.4.4), $S$ can be treated as a $\Delta^*$-ring extension of $R$ where $\delta(y_{i,\gamma}) = y_{i,\delta \gamma}$ for any $\delta \in \Delta^*$, $y_{i,\gamma} \in \Gamma Y$. In what follows we denote $y_{i,1}$ by $y_{i}$ and write $y_{i,\gamma}$ ($\gamma \in \Gamma$) as $\gamma y_{i}$.

Let $R$ be a $\Delta$-ring, $R\{(y_{i})_{i \in I}\}$ an algebra of difference polynomials in a family of $\Delta$-indeterminates $\{(y_{i})_{i \in I}\}$, and $\{(\eta_{i})_{i \in I}\}$ a set of elements in some $\Delta$-ring extension of $R$. Since the set $\{\theta_{i}|i \in I, \theta \in \Theta\}$ is algebraically independent over $R$, there exists a unique
Computation of the Strength

ring homomorphism \( \phi : R[\theta y_i \in I, \theta \in \Theta] \rightarrow R[\theta \eta_i \in I, \theta \in \Theta] \) that maps every \( \theta y_i \) onto \( \theta \eta_i \) and leaves \( R \) fixed. Clearly, \( \phi \) is a surjective \( \Delta \)-homomorphism of \( R\{y_i \in I\} \) onto \( R\{\eta_i \in I\} \); it is called the substitution of \( (\eta_i)_{i \in I} \) for \( (y_i)_{i \in I} \). Similarly, if \( R \) is a \( \Delta^* \)-ring, \( R\{y_i \in I\}^* \) an algebra of \( \Delta^* \)-polynomials over \( R \) and \( (\eta_i)_{i \in I} \) a family of elements in a \( \Delta^* \)-ring extension of \( R \), one can define a surjective \( \Delta \)-homomorphism \( R\{y_i \in I\}^* \rightarrow R\{\eta_i \in I\}^* \) that maps every \( y_i \) onto \( \eta_i \) and leaves the ring \( R \) fixed. This homomorphism is also called the substitution of \( (\eta_i)_{i \in I} \) for \( (y_i)_{i \in I} \). (It will be always clear whether we talk about substitutions for difference (\( \Delta \)-) or inversive difference (\( \Delta^* \)-) polynomials.) If \( g \) is a \( \Delta \)- or \( \Delta^* \)-polynomial, then its image under a substitution of \( (\eta_i)_{i \in I} \) for \( (y_i)_{i \in I} \) is denoted by \( g((\eta_i)_{i \in I}) \). The kernel of a substitution is a \( \Delta \)- (or \( \Delta^* \)- if we deal with difference or inversive difference polynomials) ideal of the \( \Delta \)-ring \( R\{y_i \in I\} \) (respectively, of the \( \Delta^* \)-ring \( R\{y_i \in I\}^* \) if we consider substitution for inversive difference polynomials). This kernel is called the defining \( \Delta \)- (or \( \Delta^* \)-) ideal of the family \( (\eta_i)_{i \in I} \) over \( R \).

If \( R \) is a \( \Delta \)- (or \( \Delta^* \)-) field and \( (\eta_i)_{i \in I} \) is a family of elements in some \( \Delta \)- (respectively, \( \Delta^* \)-) overfield \( S \), then \( R\{\eta_i \in I\} \) (respectively, \( R\{\eta_i \in I\}^* \)) is an integral domain (it is contained in the field \( S \)). It follows that the defining \( \Delta \)- (or \( \Delta^* \)-) ideal \( P \) of the family \( (\eta_i)_{i \in I} \) over \( R \) is a prime \( \Delta \)- (or \( \Delta^* \)- if we consider differences or inversive differences) ideal of the \( \Delta \)-ring \( R\{y_i \in I\} \) (respectively, of the ring of \( \Delta^* \)-polynomials \( R\{y_i \in I\}^* \)). Therefore, \( R\{\eta_i \in I\} \) can be treated as the quotient \( \Delta \)-field of the \( \Delta \)-ring \( R\{y_i \in I\}^*/P \). (In the case of inversive difference rings, the \( \Delta^* \)-field \( R\{\eta_i \in I\}^*/P \) can be considered as a quotient \( \Delta^* \)-field of the \( \Delta^* \)-ring \( R\{y_i \in I\}^*/P \).

Let \( K \) be a \( \Delta \)- (or \( \Delta^* \)-) field and \( s \) a positive integer. By an \( s \)-tuple over \( K \) we mean an \( s \)-dimensional vector \( a = (a_1, \ldots, a_s) \) whose coordinates belong to some \( \Delta \)- (respectively, \( \Delta^* \)-) overfield of \( K \).

**Definition II.2** Let \( K \) be a \( \Delta \)- (or \( \Delta^* \)-) field and let \( R \) be the algebra of \( \Delta \)- (respectively, \( \Delta^* \)-) polynomials in finitely many \( \Delta \)- (respectively, \( \Delta^* \)-) indeterminates \( y_1, \ldots, y_s \) over \( K \). Furthermore, let \( \Phi = \{f_j \mid j \in J\} \) be a set of \( \Delta \)- (respectively, \( \Delta^* \)-) polynomials in \( R \). An \( s \)-tuple \( \eta = (\eta_1, \ldots, \eta_s) \) over \( K \) is said to be a solution of the set \( \Phi \) or a solution of the system of algebraic \( \Delta \)- (respectively, \( \Delta^* \)-) equations \( f_j(y_1, \ldots, y_s) = 0 \ (j \in J) \) if \( \Phi \) is contained in the kernel of the substitution of \( (\eta_1, \ldots, \eta_s) \) for \( (y_1, \ldots, y_s) \). In this case we also say that \( \eta \) annihilates \( \Phi \).
Computation of the Strength

A system of algebraic difference equations $\Phi$ is called prime if the $\Delta$-ideal (or $\Delta^*$-ideal in the case of a system of difference or inversive difference equations) generated by $\Phi$ in the ring of $\Delta$ (or $\Delta^*$ - if we deal with inversive difference equations) polynomials is prime.

As we have seen, if one fixes an $s$-tuple $\eta = (\eta_1, \ldots, \eta_s)$ over a $\Delta$- ($\Delta^*$-) field $K$, then all $\Delta$- ($\Delta^*$-) polynomials of the ring $K\{y_1, \ldots, y_s\}$ (respectively, $K\{y_1, \ldots, y_s\}^*$), for which $\eta$ is a solution, form a prime $\Delta$- (respectively, $\Delta^*$-) ideal, the defining $\Delta$- (respectively, $\Delta^*$-) ideal of $\eta$. If $\Phi$ is a subset of $K\{y_1, \ldots, y_s\}$ (respectively, $K\{y_1, \ldots, y_s\}^*$), then an $s$-tuple $\eta = (\eta_1, \ldots, \eta_s)$ over $K$ is called a generic zero of $\Phi$ if for any $\Delta$- ($\Delta^*$-) polynomial $f$, the inclusion $f \in \Phi$ holds if and only if $f(\eta_1, \ldots, \eta_s) = 0$.

Two $s$-tuples $\eta = (\eta_1, \ldots, \eta_s)$ and $\zeta = (\zeta_1, \ldots, \zeta_s)$ over a $\Delta$- ($\Delta^*$-) field $K$ are called equivalent over $K$ if there is a $\Delta$-homomorphism $K\langle \eta_1, \ldots, \eta_s \rangle \to K\langle \zeta_1, \ldots, \zeta_s \rangle$ (respectively, $K\langle \eta_1, \ldots, \eta_s \rangle^* \to K\langle \zeta_1, \ldots, \zeta_s \rangle^*$) that maps each $\eta_i$ onto $\zeta_i$ and leaves the field $K$ fixed.

Proposition II.3 (see (3 (Chapter 2, Theorem VII),10 (Propositions 3.2.6, 3.3.7)). Let $R$ denote the algebra of $\Delta$- (or $\Delta^*$-) polynomials in $s$ $\Delta$- (respectively, $\Delta^*$-) indeterminates $y_1, \ldots, y_s$ over a $\Delta$- (respectively, $\Delta^*$-) field $K$.

(i) A set $\Phi \subsetneq R$ has a generic zero if and only if $\Phi$ is a prime $\Delta$- ($\Delta^*$-, if we consider differences or inversive differences) ideal of $R$. If $(\eta_1, \ldots, \eta_s)$ is a generic zero of $\Phi$, then $K\langle \eta_1, \ldots, \eta_s \rangle$ is $\Delta$-isomorphic to the $\Delta$- (respectively, $\Delta^*$-) quotient field of $R/\Phi$.

(ii) Any $s$-tuple over $K$ is a generic zero of some prime $\Delta$- ($\Delta^*$-, if we deal with difference or inversive difference polynomials) ideal of $R$. If two $s$-tuples over $K$ are generic zeros of the same prime $\Delta$- ($\Delta^*$-) ideal of $R$, then these $s$-tuples are equivalent.

2.3. Ring of differential, difference, and inversive difference operators. Differential, difference, and inversive difference modules.

Let $R$ be a differential or difference ring with a basic set $\Delta = \{\delta_1, \ldots, \delta_m\}$ and let $\Theta$ be the free commutative semigroup generated by $\Delta$. If $\theta = \delta_1^{k_1} \cdots \delta_m^{k_m} \in \Theta (k_1, \ldots, k_m \in \mathbb{N})$, then the number $\text{ord} \theta = \sum_{\nu=1}^{m} k_\nu$ is called the order of $\theta$. Furthermore, for any $r \in \mathbb{N}$, the set $\{\theta \in \Theta | \text{ord} \theta \leq r\}$ is denoted by $\Theta(r)$.

Definition II.4 An expression of the form $\sum_{\theta \in \Theta} a_\theta \theta$, where $a_\theta \in R$ for any $\theta \in \Theta$ and only finitely many elements $a_\theta$ are different from 0, is called a $\Delta$-operator over the ring $R$. (If $\Delta$ is the set of mutually commuting derivations, then a $\Delta$-operator is also called a differential operator.)
Computation of the Strength

operator; if $\Delta$ consists of mutually commuting injective endomorphisms, a $\Delta$-operator is called a difference operator). Two $\Delta$-operators $\sum_{\theta \in \Theta} a_\theta \theta$ and $\sum_{\theta \in \Theta} b_\theta \theta$ are considered to be equal if and only if $a_\theta = b_\theta$ for all $\theta \in \Theta$.

The set of all $\Delta$-operators over a $\Delta$-ring $R$ can be equipped with a ring structure if we set $\sum_{\theta \in \Theta} a_\theta \theta + \sum_{\theta \in \Theta} b_\theta \theta = \sum_{\theta \in \Theta} (a_\theta + b_\theta) \theta$, $a \sum_{\theta \in \Theta} a_\theta \theta = \sum_{\theta \in \Theta} (a a_\theta) \theta$, $(\sum_{\theta \in \Theta} a_\theta \theta) \theta_1 = \sum_{\theta \in \Theta} a_\theta (\theta \theta_1)$, $\delta a = a \delta + \delta(a)$ (respectively, $\delta a = \delta(a) \delta$ if $R$ is a difference ring and $\Delta$ is the basic set of endomorphisms of $R$) for any $\Delta$-operators $\sum_{\theta \in \Theta} a_\theta \theta$, $\sum_{\theta \in \Theta} b_\theta \theta$ and for any $a \in R, \delta \in \Delta$, and extend the multiplication by distributivity. The ring obtained in this way is called the ring of $\Delta$-operators over $R$; it will be denoted by $\mathcal{D}$. (If $\Delta$ is a set of derivations, $\mathcal{D}$ is also said to be the ring of differential operators over the differential ring $R$; if $\Delta$ is a set of endomorphisms, $\mathcal{D}$ is called the ring of difference operators over $R$.)

The order of a nonzero $\Delta$-operator $A = \sum_{\theta \in \Theta} a_\theta \theta \in \mathcal{D}$ is defined as the number $\text{ord} A = \max \{\text{ord} \theta \mid a_\theta \neq 0\}$. We also set $\text{ord} 0 = -\infty$.

Let $\mathcal{D}_r = \{A \in \mathcal{D} \mid \text{ord} A \leq r\}$ for any $r \in \mathbb{N}$ and let $\mathcal{D}_r = 0$ for any $r \in \mathbb{Z}, r < 0$. Then the ring $\mathcal{D}$ can be treated as a filtered ring with the ascending filtration $(\mathcal{D}_r)_{r \in \mathbb{Z}}$. Below, while considering $\mathcal{D}$ as a filtered ring, we always mean this filtration.

**Definition II.5** Let $R$ be a $\Delta$-ring and $\mathcal{D}$ the ring of $\Delta$-operators over $R$. Then a left $\mathcal{D}$-module is called a $\Delta$-$R$-module. (If $\Delta$ is a set of derivations, we also use the term differential $R$-module; if $\Delta$ is a set of endomorphisms, we use the term difference $R$-module). In other words, an $R$-module $M$ is a $\Delta$-$R$-module if the elements of $\Delta$ act on $M$ in such a way that $\delta(x + y) = \delta(x) + \delta(y)$, $\delta(\delta' x) = \delta'(\delta x)$, and $\delta(ax) = \delta(a)x + a \delta(x)$ (if $\Delta$ consists of derivations, so $\Delta$- means "differential") or $\delta(ax) = \delta(a) \delta(x)$ (if $\Delta$ consists of endomorphisms, so $\Delta$- means "difference") for any $x, y \in M; \delta, \delta' \in \Delta; a \in R$. If $R$ is a $\Delta$-field, then a $\Delta$-$R$-module $M$ is also called a vector $\Delta$-$R$-space.

If $R$ is an inversive difference ring with basic set $\Delta = \{\delta_1, \ldots, \delta_m\}$ and $\Gamma$ is the free commutative group generated by $\Delta$, then the order of an element $\gamma = \delta_1^{k_1} \ldots \delta_m^{k_m} \in \Gamma$ ($k_1, \ldots, k_m \in \mathbb{Z}$) is defined as $\text{ord} \gamma = \sum_{\nu = 1}^m |k_\nu|$. Also, for any $r \in \mathbb{N}$, we set $\Gamma(r) = \{\gamma \in \Gamma \mid \text{ord} \gamma \leq r\}$. In this case, by a $\Delta^*$-operator we mean an expression of the form $\sum_{\gamma \in \Gamma} a_\gamma \gamma$, where $a_\gamma \in R$ for any $\gamma \in \Gamma$ and only finitely many elements $a_\gamma$ are different from 0. As in the case of $\Delta$-operators, two $\Delta^*$-operators are considered to be equal if and only if for any $\gamma \in \Gamma$, the coefficients of $\gamma$ in these operators are the same.
Computation of the Strength

Clearly, a $\Delta^*$-ring $R$ can be also treated as a $\Delta$-ring, so every $\Delta$-operator over $R$ can be also considered as a $\Delta^*$-operator. The set of all $\Delta^*$-operators over the ring $R$ can be naturally considered as a ring extension of the ring $D$ of $\Delta$-operators over $R$ where the operation are defined in the same way as they are defined in $D$ with additional rules $\delta^{-1}a = \delta^{-1}(a)\delta^{-1}$ and $\delta\delta^{-1} = \delta^{-1}\delta = 1$ ($a \in R$, $\delta \in \Delta$) extended by distributivity. The resulting ring will be denoted by $D^*$; it is called the ring of $\Delta^*$-operators (or inversive difference operators) over $R$. A left $D^*$-module is called a $\Delta^*$-module (or an inversive difference $R$-module). Such a module is actually a $\Delta$-$R$-module $M$ with an additional action of the elements of the form $\delta^{-1}$ ($\delta \in \Delta$) such that $\delta(\delta^{-1}(x)) = \delta^{-1}(\delta(x))$ for any $x \in M$ (the other rules are the same as in Definition II.5 except for that the elements $\delta$ and $\delta'$ are taken from the set $\Delta^*$ rather than from $\Delta$).

The order of a nonzero $\Delta^*$-operator $A = \sum_{\gamma \in \Gamma} a_\gamma \gamma \in D^*$ is defined as the number $\text{ord } A = \max\{\text{ord } \gamma | a_\gamma \neq 0\}$, and we also set $\text{ord } 0 = -\infty$. The ring $D^*$ will be treated as a filtered ring with the ascending filtration $(D^*_r)_{r \in \mathbb{Z}}$ where $D^*_r = \{A \in D^*| \text{ord } A \leq r\}$ for any $r \in \mathbb{N}$ and $D^*_r = 0$ for any $r \in \mathbb{Z}, r < 0$.

III. DIFFERENTIAL AND DIFFERENCE DIMENSION POLYNOMIALS

In this section we present main theorems on dimension polynomials of differential and difference modules and field extensions. Then we show how one can determine the strength of a system of partial differential or difference equations by computing the corresponding dimension polynomial.

With the above notation, let $R$ be a $\Delta$- (respectively, $\Delta^*$-) ring. We say that a $\Delta$-$R$-module (respectively, $\Delta^*$-$R$-module) $M$ is finitely generated, if it is finitely generated as a left $D$- (respectively, $D^*$-) module. By a filtered $\Delta$- (respectively, $\Delta^*$-) module we always mean a left $D$- (respectively, $D^*$-) module $M$ equipped with an exhaustive and separated filtration. Thus, a filtration of $M$ is an ascending chain $(M_r)_{r \in \mathbb{Z}}$ of $R$-submodules of $M$ such that $D_r M_s \subseteq M_{r+s}$ (respectively, $D^*_r M_s \subseteq M_{r+s}$) for all $r, s \in \mathbb{Z}$, $M_r = 0$ for all sufficiently small $r \in \mathbb{Z}$, and $\bigcup_{r \in \mathbb{Z}} M_r = M$. A filtration $(M_r)_{r \in \mathbb{Z}}$ of $M$ is called excellent if all $R$-modules $M_r$ ($r \in \mathbb{Z}$) are finitely generated and there exists $r_0 \in \mathbb{Z}$ such that $M_r = D_{r-r_0} M_{r_0}$ (respectively, $M_r = D^*_{r-r_0} M_{r_0}$) for any $r \in \mathbb{Z}, r \geq r_0$. Note that if $R$ is a $\Delta$-field and $M$ is a
Computation of the Strength

finitely generated $\Delta$-$R$-module,

$$M = \sum_{i=1}^{s} Df_i$$

for some $f_1, \ldots, f_s \in M$, then

$$\left( M_r = \sum_{i=1}^{s} D_r f_i \right)_{r \in \mathbb{Z}}$$

is an excellent filtration of $M$, and a similar remark can be made about a finitely generated $\Delta^*$-$R$-module.

The following result combines theorems on dimension polynomials of differential and difference modules obtained in\textsuperscript{7} and\textsuperscript{12} (see also\textsuperscript{10} (Theorems 5.1.11, 6.2.5 and Propositions 5.2.12, 6.2.17)).

**Theorem III.1** Let $R$ be a $\Delta$-field whose basic set consists of $m$ operators (derivations or injective endomorphisms). Let $D$ be the ring of $\Delta$-operators over $R$, and let $(M_r)_{r \in \mathbb{Z}}$ be an excellent filtration of a $\Delta$-$R$-module $M$. Then there exists a polynomial $\psi(t) \in \mathbb{Q}[t]$ with the following properties.

(i) $\psi(r) = \dim_R(M_r)$ for all sufficiently large $r \in \mathbb{Z}$, that is, there exists $r_0 \in \mathbb{Z}$ such that the last equality holds for all integers $r \geq r_0$. (as usual, $\dim_R(M_r)$ denotes the dimension of the vector $R$-space $M_r$).

(ii) $\deg \psi(t) \leq m$ and the polynomial $\psi(t)$ can be written as

$$\psi(t) = \sum_{i=0}^{m} c_i \binom{t + i}{i}$$

where $c_0, c_1, \ldots, c_m \in \mathbb{Z}$ and

$$\binom{t + i}{i} = \frac{(t + i)(t + i - 1) \ldots (t + 1)}{i!}$$

(this polynomial takes integer values for all sufficiently large integer values of $t$).

(iii) The integers $d = \deg \psi(t)$, $c_m$ and $c_d$ (if $d < m$) do not depend on the choice of the excellent filtration of $M$. Furthermore, $c_m$ is equal to the maximal number of elements of $M$ linearly independent over the ring $D$.

The polynomial $\psi(t)$ whose existence is established by Theorem III.1 is called the $\Delta$-dimension polynomial (differential or difference dimension polynomial depending on the nature of the set $\Delta$) of the $\Delta$-$R$-module $M$ associated with the excellent filtration $(M_r)_{r \in \mathbb{Z}}$.\textsuperscript{13}
Computation of the Strength

The integers \(d, c_m, \) and \(c_d\) are called the \(\Delta\)-type, \(\Delta\)-dimension, and typical \(\Delta\)-dimension of \(M\), respectively. A number of results on differential and difference dimension polynomials, as well as some methods of their computation, can be found in\(^{10}\) (Chapters 5 - 9).

The following is an analog of Theorem III.1 for inversive difference modules (see\(^{10}\) (Theorem 6.3.3 and Proposition 6.3.15) or\(^{18}\) (Theorems 3.5.2, 3.5.8)).

**Theorem III.2** Let \(R\) be a \(\Delta^\ast\)-field whose basic set \(\Delta\) consists of \(m\) automorphisms of \(R\), and let \((M_r)_{r\in\mathbb{Z}}\) be an excellent filtration of a \(\Delta^\ast\)-\(R\)-module \(M\). Then there exists a polynomial \(\chi(t)\) in one variable \(t\) with rational coefficients such that

(i) \(\chi(r) = \dim_R(M_r)\) for all sufficiently large \(r \in \mathbb{Z}\);

(ii) \(\deg \chi(t) \leq m\) and the polynomial \(\chi(t)\) can be represented in the form

\[\chi(t) = \frac{2^m a}{m!} t^m + o(t^m)\]

where \(a \in \mathbb{Z}\) and \(o(t^n)\) is a polynomial in \(\mathbb{Q}[t]\) of degree less than \(m\).

(iii) The integers \(a, d = \deg \chi(t)\) and the coefficient of \(t^d\) in the polynomial \(\chi(t)\) do not depend on the choice of the excellent filtration of \(M\). Furthermore, \(a\) is equal to the maximal number of elements of \(M\) linearly independent over the ring \(\mathcal{D}^\ast\).

The polynomial \(\chi(t)\) is called the \(\Delta^\ast\)-dimension polynomial of the \(\Delta^\ast\)-\(R\)-module \(M\) associated with the excellent filtration \((M_r)_{r\in\mathbb{Z}}\).

The next result combines Kolchin’s theorem on differential dimension polynomial\(^9\) (Chapter II, Theorem 6) and the corresponding result for difference field extensions proved in\(^{12}\).

**Theorem III.3** Let \(K\) be a \(\Delta\)-field whose basic set consists of \(m\) operators (derivations or endomorphisms). Let \(L = K\langle \eta_1, \ldots, \eta_s \rangle\) be a \(\Delta\)-field extension of \(K\) generated by a finite family \(\eta = \{\eta_1, \ldots, \eta_s\}\). Then there exists a polynomial \(\phi_{\eta|K}(t) \in \mathbb{Q}[t]\) with the following properties.

(i) \(\phi_{\eta|K}(r) = \text{trdeg}_K K((\theta \eta_j \mid \theta \in \Theta(r), 1 \leq j \leq s))\) for all sufficiently large \(r \in \mathbb{N}\).

(ii) \(\deg \phi_{\eta|K}(t) \leq n\) and the polynomial \(\phi_{\eta|K}(t)\) can be written as

\[\phi_{\eta|K}(t) = \sum_{i=0}^{m} a_i \binom{t+i}{i}\]

where \(a_0, \ldots, a_m \in \mathbb{Z}\).
Computation of the Strength

(iii) The integers $a_m, d = \deg \phi_{\eta|K}(t)$ and $a_d$ are invariants of the polynomial $\phi_{\eta|K}(t)$, that is, they do not depend on the choice of a system of $\sigma$-generators $\eta$. Furthermore, $a_m = \Delta\text{-trdeg}_{KL}$ where $\Delta\text{-trdeg}_{KL}$ denotes the $\Delta$-transcendence degree of $L$ over $K$, that is, the maximal number of elements $\xi_1, \ldots, \xi_k \in L$ such that the family $\{\theta \xi_i | \theta \in \Theta, 1 \leq i \leq k\}$ is algebraically independent over $K$.

The polynomial $\phi_{\eta|K}(t)$ whose existence is established by Theorem III.3 is called the $\Delta$-(differential or difference depending on the nature of $\Delta$) dimension polynomial of the $\Delta$-field extension $L$ of $K$ associated with the system of $\Delta$-generators $\eta$. The integers $d = \deg \phi_{\eta|K}(t)$ and $a_d$ are called, respectively, the $\Delta$-type and typical $\Delta$-transcendence degree of $L$ over $K$. These invariants of $\phi_{\eta|K}(t)$ are denoted by $\Delta\text{-type}_{KL}$ and $\Delta\text{-t.trdeg}_{KL}$, respectively.

Notice that if the elements $\eta_1, \ldots, \eta_s$ are $\Delta$-algebraically independent over $K$ (that is, the set $\{\theta \eta_i | \theta \in \Theta, 1 \leq i \leq s\}$ is algebraically independent over $K$) and $\phi_{\eta|K}(t)$ is the corresponding difference dimension polynomial of $L/K$ (we use the notation of the last theorem), then

$$\phi_{\eta|K}(r) = \text{trdeg}_{KL}(\{\tau \eta_j | \tau \in \Gamma, 1 \leq j \leq s\}) = s \cdot \text{Card}(r) = s \left( r + m \right)$$

for all sufficiently large $r \in \mathbb{N}$ ($\text{Card}(r)$ is the number of solutions $(k_1, \ldots, k_m) \in \mathbb{N}^m$ of the inequality $k_1 + \cdots + k_m \leq r$; it is well known (see, for example, Proposition 2.1.9)) that this number is $\left( \frac{r+m}{m} \right)$. Therefore, in this case

$$\phi_{\eta|K}(t) = s \left( t + m \right).$$

The following theorem shows the existence of a dimension polynomial of a finitely generated inversive difference field extension.

**Theorem III.4** Let $K$ be a $\Delta^*$-field whose basic set $\Delta$ consists of $m$ automorphisms of $K$. As before, let $\Gamma$ be the free commutative group generated by $\Delta$, and for any $r \in \mathbb{N}$, let $\Gamma(r) = \{\gamma \in \Gamma | \text{ord} \gamma \leq r\}$. Furthermore, let $L = K(\eta_1, \ldots, \eta_s)^*$ be a $\Delta^*$-field extension of $K$ generated by a finite family $\eta = \{\eta_1, \ldots, \eta_s\}$. Then there exists a polynomial $\psi_{\eta|K}(t) \in \mathbb{Q}[t]$ with the following properties.

(i) $\psi_{\eta|K}(r) = \text{trdeg}_{KL}(\{\gamma \eta_j | \gamma \in \Gamma(r), 1 \leq j \leq s\})$ for all sufficiently large $r \in \mathbb{N}$.
Computation of the Strength

(ii) \( \deg \psi_{\eta|K}(t) \leq m \) and the polynomial \( \psi_{\eta|K}(t) \) can be written as

\[
\psi_{\eta|K}(t) = \frac{2^m a}{m!} t^m + o(t^m)
\]

where \( a \in \mathbb{Z} \) and \( o(t^m) \) is a polynomial in \( \mathbb{Q}[t] \) of degree less than \( m \).

(iii) The integers \( a, d = \deg \psi_{\eta|K}(t) \) and the coefficient of \( t^d \) in the polynomial \( \psi_{\eta|K}(t) \) do not depend on the choice of a system of generators \( \eta \). Furthermore, \( a = \Delta-\text{trdeg}_K L \).

(iv) If \( \eta_1, \ldots, \eta_s \) are \( \Delta \)-algebraically independent over \( K \), then

\[
\psi_{\eta|K}(t) = s \sum_{k=0}^{m} (-1)^{m-k} 2^k \binom{m}{k} \binom{t+k}{k}.
\]

Let us consider a prime system of algebraic \( \Delta \)- (differential or difference) or \( \Delta^* \)- (inversive difference) equations

\[
A_i(y_1, \ldots, y_s) = 0 \quad (i = 1, \ldots, p)
\]

where \( A_i(y_1, \ldots, y_s) \) are \( \Delta \)- (or \( \Delta^* \)-) polynomials in the ring \( R = K\{y_1, \ldots, y_s\} \) (respectively, in \( R = K\{y_1, \ldots, y_s\}^* \)) and let \( P \) be a prime \( \Delta \)-ideal (respectively a prime \( \Delta^* \)-ideal if we consider the difference or inverse difference case) of \( R \) generated by the right-hand sides of system (1). Furthermore, let \( \eta_i \) be the canonical image of \( y_i \) in the factor ring \( R/P \) \((1 \leq i \leq s)\). It is easy to see that for every \( r \in \mathbb{N} \) the intersection \( P \cap R_r \) is a prime ideal of the ring \( R_r \) and the quotient fields of the rings \( R_r/P \cap R_r \) and \( K[\{\theta(\eta_j) \mid \theta \in \Theta(r), 1 \leq j \leq s\}] \) (respectively, \( K[\{\gamma(\eta_j) \mid \gamma \in \Gamma(r), 1 \leq j \leq s\}] \)) are isomorphic. Considering the case of algebraic differential or difference equations we can apply Theorem III.3 and obtain that there exists a polynomial \( \phi_P(t) \) in one variable \( t \) with rational coefficients such that

\[
\phi_P(t) = \text{trdeg}_K K(\{\theta(\eta_j) \mid \theta \in \Theta(r), 1 \leq j \leq s\}) = \text{trdeg}_K (R_r/P \cap R_r)
\]

for all sufficiently large \( r \in \mathbb{Z} \), \( \deg \phi_P(t) \leq m \) and the polynomial \( \phi_P(t) \) can be written as

\[
\phi_P(t) = \sum_{i=0}^{m} a_i \binom{t+i}{i}
\]

where \( a_0, \ldots, a_m \in \mathbb{Z} \) and \( a_m = \Delta-\text{trdeg}_K K(\{\theta(\eta_j) \mid \theta \in \Theta(r), 1 \leq j \leq s\}) \).

In the case of a system of difference equations (including the case when such a system involves negative degrees of basic translations, which act as automorphisms), one can apply Theorem III.4 that shows the existence of a polynomial \( \psi_P(t) \in \mathbb{Q}[t] \) such that

\[
\psi_P(r) = \text{trdeg}_K K(\{\gamma(\eta_j) \mid \gamma \in \Gamma(r), 1 \leq j \leq s\}) = \text{trdeg}_K (R_r/P \cap R_r)
\]
Computation of the Strength

for all sufficiently large \( r \in \mathbb{Z} \), \( \deg \psi(t) \leq m \) and the polynomial \( \psi_P(t) \) can be written as

\[
\psi_P(t) = \frac{2^n a_P t^n}{n!} + o(t^n)
\]

where \( a_P = \sigma - \text{trdeg}_K(R/P) \).

With the above notation, the numerical polynomial \( \phi_P(t) \) (respectively, \( \psi_P(t) \)) is called a differential (respectively, difference) dimension polynomial of system (1). It is also said to be a \( \Delta^- \) (respectively, \( \Delta^*^- \)) dimension polynomial of the system.

Taking into account Einstein’s approach described in the Introduction, one can say that for all sufficiently large \( r \), the value \( \phi_P(r) \) of the differential dimension polynomial \( \phi_P(t) \) of a system of algebraic differential equations is the number of Taylor coefficients of order \( \leq r \) of an analytic solution that can be chosen arbitrarily. (These Taylor coefficients are the values of derivatives of order \( \leq r \) of the solution computed at the point in whose neighborhood we consider its expansion. The dependence of coefficients is understood as their algebraic dependence over the field of coefficients of the system.) Thus, \( \phi_P(t) \) can be viewed as a measure of strength of system (1), so the problem of computation of differential dimension polynomials is important not only for the study of differential algebraic structures, but also for the study of equations of mathematical physics.

Considering a system of equations in finite differences over a field of functions in several real variables, one can use Einstein’s approach to define the concept of strength of such a system as follows (cf. Einstein’s description of the strength of a system of PDEs presented in the Introduction). Let

\[
A_i(f_1, \ldots, f_s) = 0 \quad (i = 1, \ldots, p)
\]

be a system of equations in finite differences with respect to \( s \) unknown grid functions \( f_1, \ldots, f_s \) in \( n \) real variables \( x_1, \ldots, x_n \) with coefficients in some functional field \( K \). We also assume that the difference grid, whose nodes form the domain of considered functions, has equal cells of dimension \( h_1 \times \cdots \times h_n \) \((h_1, \ldots, h_n \in \mathbb{R})\) and fills the whole space \( \mathbb{R}^n \). As an example, one can consider a field \( K \) consisting of a zero function and fractions of the form \( u/v \) where \( u \) and \( v \) are grid functions defined almost everywhere and vanishing at at most finitely many nodes. (As usual, we say that a grid function is defined almost everywhere if there are at most finitely many nodes where it is not defined.)
Computation of the Strength

Let us fix some node $P$ and say that a node $Q$ has order $i$ (with respect to $P$) if the shortest path from $P$ to $Q$ along the edges of the grid consists of $i$ steps (by a step we mean a path from a node of the grid to a neighboring node along the edge between these two nodes). Say, the orders of the nodes in the two-dimensional case are as follows (a number near a node shows the order of this node). Let us consider the values of the unknown grid functions $f_1, \ldots, f_s$ at the nodes whose order does not exceed $r$ ($r \in \mathbb{N}$). If $f_1, \ldots, f_s$ should not satisfy any system of equations (or any other condition), their values at nodes of any order can be chosen arbitrarily. Because of the system in finite differences (and equations obtained from the equations of the system by transformations of the form $f_j(x_1, \ldots, x_s) \mapsto f_j(x_1 + k_1 h_1, \ldots, x_s + k_n h_n)$ with $k_1, \ldots, k_n \in \mathbb{Z}$, $1 \leq j \leq s$), the number of independent values of the functions $f_1, \ldots, f_s$ at the nodes of order $\leq r$ decreases. This number, which is a function of $r$, is considered as a ”measure of strength” of the system in finite differences (in the sense of Einstein). We denote it by $S_r$.

With the above conventions, suppose that the transformations $\alpha_j$ of the field of coefficients $K$ defined by

$$\alpha_j f(x_1, \ldots, x_n) = f(x_1, \ldots, x_{j-1}, x_j + h_j, \ldots, x_n)$$

($1 \leq j \leq n$) are automorphisms of this field. Then $K$ can be considered as an inversive difference field with the basic set $\sigma = \{\alpha_1, \ldots, \alpha_n\}$. The replacement of the unknown functions $f_i$ by difference indeterminates $y_i$ ($i = 1, \ldots, s$) leads to a system of algebraic difference equations of the form (1). If this system is prime (e.g., we deal with a system of linear difference equations), then its difference dimension polynomial $\psi(t)$ expresses the strength $S_r$. Thus, this polynomial can be naturally viewed as the measure of Einstein’s strength of a
Computation of the Strength

given system of equations in finite differences. In what follows, the $\Delta^*$-dimension polynomial $\psi(t)$ will be called the difference dimension polynomial of the system.

Methods of computation of $\Delta$- and $\Delta^*$-dimension polynomials of a system of algebraic partial differential or difference equations developed so far are based either on building of a characteristic set of the considered above associated $\Delta$-(or $\Delta^*$-) ideal $P$ in $K\{y_1, \ldots, y_s\}$ or on constructing a free resolution of the module of Kähler differentials associated with the extension $K\langle \eta_1, \ldots, \eta_s \rangle$ (or $K\langle \eta_1, \ldots, \eta_s \rangle^*$). The corresponding computations can be found, for example, in \(^{10}\) (Chapter 9) and \(^{18}\) (Chapter 7). The main drawback of the mentioned approaches is the lack of efficient algorithms for constructing characteristic sets and serious restrictions on the systems to which one can apply the method of free resolutions. In the last case, a system of difference equations with inversive difference operators is supposed to be linear and symmetric, that is, whenever an equation involves a $\Delta^*$-operator $\omega = a_1\delta_{k_11} \ldots \delta_{k_m} + \cdots + a_r\delta_{k_11} \ldots \delta_{k_mr}$ ($a_i \in K$), which contains a term $a\delta_{l_1} \ldots \delta_{l_m}$ ($a \in K$, $a \neq 0$), then it also contains all terms of the form $b\delta_{l_1} \ldots \delta_{l_m}$ with nonzero coefficients $b \in K$ and all $2^m$ distinct combinations of signs before $l_1, \ldots, l_m$. In what follows we explain a method of computation of dimension polynomials (and therefore, the strength of a system of algebraic partial differential or difference equations), which does not have these restrictions.

Implementations for computing Gröbner bases in modules of differential and difference operators are available, e.g., in the Mgfun package\(^2\) for Maple or in the Plural extension of Singular\(^{11}\).

IV. COMPUTATION OF THE STRENGTH OF A SYSTEM OF DIFFERENCE EQUATIONS VIA GRÖBNER AND GENERALIZED GRÖBNER BASIS TECHNIQUES. EXAMPLES

Let $K$ be a difference or inversive difference field of characteristic 0 with basic set $\Delta = \{\delta_1, \ldots, \delta_m\}$. As we have seen, the ring of $\Delta$-operators over $K$ carries many properties of a polynomial ring in $m$ variables over $K$. In order to underline the relationship between the Gröbner basis method for $\Delta$-$K$-modules considered below and the classical Gröbner basis technique for polynomial ideals we will denote the ring of $\Delta$-operators over $K$ by $K[\Delta]$ and set

$$[\Delta] := \{\delta_{k_1} \ldots \delta_{k_m} \mid k_1, \ldots, k_m \in \mathbb{N}\}. $$
Computation of the Strength

Similarly, if $\Delta$ is a family of mutually commuting automorphisms of $K$, we set

$$[\Delta^*] := \{\delta_1^{k_1} \cdots \delta_m^{k_m} \mid k_1, \ldots, k_m \in \mathbb{Z}\}$$

and denote the ring of $\Delta^*$-operators over $K$ by $K[\Delta^*]$. Furthermore, a free left $K[\Delta]$- (respectively, $K[\Delta^*]$-) module with a set of free generators $E = \{e_1, \ldots, e_q\}$ will be denoted by $K[\Delta]E$ (respectively, $K[\Delta^*]E$) and $[\Delta]E$ (respectively, $[\Delta^*]E$) will denote the set of all elements of the form $\lambda e_i$ where $1 \leq i \leq q$ and $\lambda \in [\Delta]$ (respectively, $\lambda \in [\Delta^*]$). Such elements of the free module are called terms.

Let $E = \{e_1, \ldots, e_q\}$ be a finite set of free generators of the left $K[\Delta^*]$ module $K[\Delta^*]E$ and $F \subseteq K[\Delta^*]E$ finite. There are two popular approaches for computing a Gröbner basis of the left $K[\Delta^*]$-module $K[\Delta^*]E\langle F \rangle$. The first approach is due to the second author\textsuperscript{16,18} – the idea also appears\textsuperscript{19} – works by introducing new variables for the inverses $\delta_1^{-1}, \ldots, \delta_m^{-1}$ of $\delta_1, \ldots, \delta_m$ and doing computations in the resulting free module of difference operators. The second approach, originated by the second author\textsuperscript{13}, was enhanced by Winkler and Zhou\textsuperscript{31,32} who introduced the concept of so-called generalized term orders therefore making $K[\Delta^*]E$ a well-ordered set. In the following we will outline the first approach. Proofs for termination and correctness of the algorithms can be found, e.g., in\textsuperscript{16,18,19}.

A. Computing Gröbner bases of inversive difference modules via standard bases of associated difference modules

Let $K$ be a differential (respectively, difference) field with basic set $\Delta = \{\delta_1, \ldots, \delta_m\}$ of derivations (respectively, endomorphisms) of $K$.

**Definition IV.1** Let $\prec$ be a total order on the set of terms $[\Delta]E$ such that for all elements $1 \neq \lambda, \eta, \mu \in [\Delta], e, e' \in E$ we have

1. $e \prec \lambda e$,

2. $\mu \lambda e \prec \mu \eta e'$ whenever $\lambda e \prec \eta e'$.

Then the relation $\prec$ is called an admissible order.

For any $f = a_1 f_1 + \ldots + a_n f_n \in K[\Delta]E$ with $a_1, \ldots, a_n \in K, f_1, \ldots, f_n \in [\Delta]E$ and for a given admissible order $\prec$ we denote the highest term appearing in $f$ with nonzero coefficient
Algorithm 1: Reduction_algorithm

IN: $0 \neq f \in K[\Delta]E$, finite $G \subseteq K[\Delta]E$, and an admissible order $\prec$,

OUT: $r \in K[\Delta]E$ such that $f$ is reducible to $r$ modulo $G$ and $r$ is irreducible modulo $G$.

$r := f$

while there exist $g \in G$ and $\lambda \in \Delta$ such that $\text{lt}(\lambda g) = \text{lt}(r)$ do

$r := r - \frac{\text{lc}(r)}{\text{lc}(g)} g$

end while

return $r$

by $\text{lt}(f)$, i.e.,

$$\text{lt}(f) := \max\{f_i \mid 1 \leq i \leq n, a_i \neq 0\},$$

and call it the leading term of $f$. The corresponding coefficient is called the leading coefficient of $f$ and is denoted by $\text{lc}(f)$.

Definition IV.2 Let $f, g \in K[\Delta]E \setminus \{0\}$ and $\prec$ an admissible order. If there exists $\lambda \in \Delta$ with $\text{lt}(\lambda g) = \text{lt}(f)$ we say that $f$ is reducible to $h := f - \frac{\text{lc}(f)}{\text{lc}(g)} g$ modulo $g$ and write

$$f \rightarrow_g h.$$

Otherwise we say that $f$ is irreducible modulo $g$. Let $G = \{g_1, \ldots, g_p\} \subseteq K[\Delta]E \setminus \{0\}$. If there exist $n \in \mathbb{N}, f_0, \ldots, f_n, i_1, \ldots, i_n \in \{1, \ldots, p\}$ such that

$$f = f_0 \rightarrow_{g_{i_1}} f_1 \rightarrow_{g_{i_2}} \cdots \rightarrow_{g_{i_n}} f_n =: r$$

we say that $f$ is reducible to $r$ modulo $G$. Otherwise we say that $f$ is irreducible modulo $G$.

The process of reduction is described by the following algorithm.

Definition IV.3 Let $\prec$ be an admissible order, $N$ a submodule of $K[\Sigma]E$ and $G \subseteq N \setminus \{0\}$ finite such that every $0 \neq f \in N$ is reducible to $0$ modulo $G$. Then $G$ is called a Gröbner basis of the module $N$.

Every finitely generated $K[\Delta]$-module $M$ has a Gröbner basis that can be computed, e.g., via Buchberger’s algorithm starting with any finite generating set $\tilde{G}$ of $M$ (see Algorithm 2 below).
Computation of the Strength

Algorithm 2: Buchberger’s algorithm

IN: \( \tilde{G} \subseteq K[\Delta]E \setminus \{0\} \) finite, \( \prec \) an admissible order,

OUT: \( G \subseteq K[\Delta]E \setminus \{0\} \) being a Gröbner basis of \( K[\Delta]\langle \tilde{G} \rangle \).

\[
G := \tilde{G} \\
\text{while there exists } g, g' \in G \text{ such that } S(g, g') \text{ is not reducible to 0 modulo } G \text{ do} \\
G := G \cup \{\text{Reduction algorithm}(S(g, g'), G, \prec)\} \\
\text{end while} \\
\text{return } G
\]

Definition IV.4 Let \( \prec \) be an admissible order on \( [\Delta]E \), \( g_1, g_2 \in K[\Delta]E \setminus \{0\} \), \( \lambda_1, \lambda_2 \in [\Delta], e_1, e_2 \in E \) such that \( \text{lt}_\prec(g_1) = \lambda_1 e_1 \) and \( \text{lt}_\prec(g_2) = \lambda_2 e_2 \). The least common multiple \( \text{lcm}(\text{lt}_\prec(g_1), \text{lt}_\prec(g_2)) \) of \( \text{lt}_\prec(g_1) \) and \( \text{lt}_\prec(g_2) \) is defined by

\[
\text{lcm}(\text{lt}_\prec(g_1), \text{lt}_\prec(g_2)) :=
\begin{cases} 
\text{lcm}(\lambda_1, \lambda_2)e_1 & \text{if } e_1 = e_2, \\
0 & \text{if } e_1 \neq e_2.
\end{cases}
\]

Let \( u_1, u_2 \in [\Delta] \) be given by

\[
u_1 := \frac{\text{lcm}(\text{lt}_\prec(g_1), \text{lt}_\prec(g_2))}{\text{lt}_\prec(g_1)} \quad \text{and} \quad u_2 := \frac{\text{lcm}(\text{lt}_\prec(g_1), \text{lt}_\prec(g_2))}{\text{lt}_\prec(g_2)}.
\]

Then the S-polynomial \( S(g_1, g_2) \) of \( g_1 \) and \( g_2 \) is defined by

\[
S(g_1, g_2) := u_1 \frac{g_1}{\text{lcm}(g_1)} - u_2 \frac{g_2}{\text{lcm}(g_2)}.
\]

The following theorem being a special case of\textsuperscript{15} (Thm. 4.12) and\textsuperscript{18} (Thm. 3.3.15) describes how to obtain the dimension polynomial associated with a system of differential or difference equations.

Theorem IV.5 Let \( M \) be a difference \( K \)-vector space generated (as a left \( K[\Delta] \)-module) by elements \( m_1, \ldots, m_q \), \( F \) a free \( K[\Delta] \)-module with set of free generators \( E = \{e_1, \ldots, e_q\} \), \( \pi : F \rightarrow M \) the difference epimorphism \( (e_i \mapsto m_i \text{ for } i = 1, \ldots, q) \) and \( N := \ker(\pi) \). Let \( G \subseteq K[\Delta]E \) be a Gröbner basis of \( N \) with respect to the term order \( \prec \) defined by

\[
\delta_1^{k_1} \cdots \delta_m^{k_m} e_i \prec \delta_1^{l_1} \cdots \delta_m^{l_m} e_j \\
\iff (k_1 + \cdots + k_m, i, k_1, \ldots, k_m) <_{\text{lex}} (l_1 + \cdots + l_m, j, l_1, \ldots, l_m),
\]

22
Computation of the Strength

where $<_\text{lex}$ denotes the lexicographic order. For $r \in \mathbb{Z}$ let

$$M_r := \{ \lambda m \in [\Delta] \{ m_1, \ldots, m_q \} \mid \text{ord } \lambda \leq r \}$$

and

$$U_r := \{ \lambda e \in [\Delta]E \mid \text{ord } \lambda \leq r \text{ and } \lambda e \neq \mu \text{lt}_<(g) \text{ for any } g \in G, \mu \in [\Delta] \}.$$  

Then $(M_r)_{r \in \mathbb{Z}}$ is an excellent filtration of $M$ and for any $r \in \mathbb{N}$ the set $\pi(U_r)$ is a basis for the $K$-vector space $M_r$.

The following proposition is obtained from Proposition IV.6 by realizing that a term $\lambda e$ is irreducible if and only if there exist no $\eta \in [\Delta], g \in G$ with $\text{lt}(g) = \mu e$ and $\eta \mu = \lambda$.

**Proposition IV.6** With the notation of Theorem IV.5 for every $i = 1, \ldots, q$, let

$$G_i := \{ \text{lt}(g) \mid g \in G, \ \text{lt}(g) \in [\Delta]e_i \}$$

and let $\Lambda_i = (\lambda_{i,j,k}) \in \mathbb{N}^{G_i \times 2m}$ satisfy the following condition: for every $i, \xi, k \in \Lambda_i$ there exists $j \in \{1, \ldots, |G_i|\}$ with $(\lambda_{i,j,1}, \ldots, \lambda_{i,j,2m}) = (a_1, \ldots, a_m, b_1, \ldots, b_m)$.

Furthermore, for any $l, n \in \mathbb{N}$ with $1 \leq n$ and $0 \leq l \leq n$, let $A(l, n)$ denote the set of all $l$-element subsets of $\{1, \ldots, n\}$ and for every $1 \leq i \leq q, \xi \neq \xi \in A(l, |G_i|)$, let $\lambda_{i,\xi,k} := \max_{j \in \xi} \lambda_{i,j,k}$ and $\lambda_{i,\emptyset,k} := 0$. Finally, for any $1 \leq i \leq q, \xi \in A(l, |G_i|)$ let $f_{i,\xi} := \sum_{k=1}^{2m} \lambda_{i,\xi,k}$. Then

$$|U_r| = \sum_{i=1}^{r} \sum_{l=0}^{|G_i|} (-1)^l \sum_{\xi \in A(l, |G_i|)} \left( r + 2m - f_{i,\xi} \right).$$

An idea of the following kind was also by Ziming Li and Min Wu. Let $K$ be an inversive difference field with basic set of automorphisms $\Delta = \{ \delta_1, \ldots, \delta_m \}$ and $F \subseteq K[\Delta^*]E$ a finite set of generators for a left $K[\Delta^*]$ module. Let $\alpha_1, \ldots, \alpha_m, \beta_1, \ldots, \beta_m$ be endomorphisms of $K$ such that for $i = 1, \ldots, m$ and $k \in K$ we have

$$\alpha_i(k) := \delta_i(k), \quad \text{and} \quad \beta_i(k) := \delta_i^{-1}(k).$$

Then $K$ can be considered as a difference field with basic set $\Sigma := \{ \alpha_1, \ldots, \alpha_m, \beta_1, \ldots, \beta_m \}$. By $\rho : K[\Delta^*] \rightarrow K[\Sigma]/K[\Sigma] \langle \{ \alpha_1 \beta_i e - e \mid 1 \leq i \leq m, e \in E \} \rangle$ we denote the natural isomorphism

$$\rho : \delta_1^{k_1} \ldots \delta_m^{k_m} e \mapsto \alpha_1^{\max\{k_1,0\}} \ldots \alpha_m^{\max\{k_m,0\}} \beta_1^{\max\{-k_1,0\}} \ldots \beta_m^{\max\{-k_m,0\}} e \quad (e \in E).$$

23
Computation of the Strength

Let \( \tilde{F} := \rho(F) \cup \{\alpha_i\beta_i e - e \mid 1 \leq i \leq m, \ e \in E\} \). Then, \( K[\Delta^*]E/K[\Delta^*]<\tilde{F}> \) is isomorphic to \( K[\Sigma]E/K[\Sigma]<\tilde{F}> \), so in order to compute the \( \Delta^* \)-dimension polynomial of a \( \Delta^*-K \)-module \( K[\Delta^*]E/K[\Delta^*]<F> \) associated with a finite system of generators \( F \), it suffices to compute the \( \Sigma \)-dimension polynomial of the \( \Sigma-K \) module \( K[\Sigma]E/K[\Sigma]<\tilde{F}> \) associated with the set of generators \( \tilde{F} \).

B. Examples for the computation of differential and difference dimension polynomials

In this subsection we give several examples for the computation of differential dimension polynomials associated with systems of differential equations arising in mathematical physics and of difference dimension polynomials associated with their difference schemes.

Example IV.7 (Diffusion equation in 1-space)

The diffusion equation in one spatial dimension for a constant collective diffusion coefficient \( a \) and unknown function \( u(x,t) \) describing the density of the diffusing material at given position \( x \) and time \( t \) is given by

\[
\frac{\partial u(x,t)}{\partial t} = a \frac{\partial^2 u(x,t)}{\partial x^2}.
\]  

(3)

Differential dimension polynomial

Let \( K \) be a differential field with basic set \( \Delta = \{\delta_x = \frac{\partial}{\partial x}, \delta_t = \frac{\partial}{\partial t}\} \) containing \( a \) and let \( M \) be a differential \( K \)-vector space generated as \( K[\Delta] \)-module by one generator \( m \) satisfying the defining equation

\[
\delta_t m = a\delta_x^2 m.
\]

Then \( M \) is isomorphic to the factor module of a free \( K[\Delta] \)-module with free generator \( e \) by its submodule \( N \) generated by

\[
G := \{\delta_t e - a\delta_x^2 e\}.
\]

Since \( G \) consists of only one element there are no \( S \)-polynomials. Therefore \( G \) is already a Gröbner basis of \( N \) for any admissible order on \( [\Delta]e \). Let the admissible order \( < \) on \( [\Delta]e \) be given by

\[
\delta_x^k \delta_t^l e < \delta_x^{k'} \delta_t^{l'} e \iff (k_x + k_t, k_x, k_t) <_{\text{lex}} (l_x + l_t, l_x, l_t).
\]
Computation of the Strength

Then for all \(2 \leq r \in \mathbb{N}\) we have

\[
U_r = \{ \delta_x^{k_x} \delta_t^{k_t} e \mid k_x + k_t \leq r, \ \delta_x^{k_x} \delta_t^{k_t} e \text{ is irreducible modulo } G \}
\]

\[
= \{ e, \delta_t e, \ldots, \delta_t^r e, \delta_x e, \delta_x \delta_t e, \ldots, \delta_x \delta_t^{r-1} e \},
\]

and therefore \(|U_r| = 2r + 1\).

Thus, the differential dimension polynomial associated with the diffusion equation in one spatial dimension for a constant collective diffusion coefficient is given by \(\phi(r) = 2r + 1\).

**Difference dimension polynomial for forward difference scheme**

In order to obtain a forward difference scheme for the diffusion equation (3) every occurrence of \(\frac{\partial u(x,t)}{\partial x}\) and \(\frac{\partial u(x,t)}{\partial t}\) is replaced by \(u(x + 1, t) - u(x, t)\) and \(u(x, t + 1) - u(x, t)\), respectively. We obtain

\[
u(x, t + 1) - u(x, t) = a(u(x + 2, t) - 2u(x + 1, t) + u(x, t)).
\] (4)

Let \(K\) be an inversive difference field with basic set \(\Delta = \{ \delta_x : x \mapsto x + 1, \delta_t : t \mapsto t + 1 \}\) containing \(a\) and let \(M\) be an inversive difference \(K\)-vector space generated as a left \(K[\Delta^*]\)-module by one generator \(m\) satisfying the defining equation

\[
\delta_t m - m = a(\delta_x^2 m - 2\delta_x m + m).
\]

Then \(M\) is isomorphic to the factor module of a free \(K[\Delta^*]\)-module with free generator \(e\) by its submodule \(N\) generated by

\[
G := \{ \delta_t e - a\delta_x^2 e + 2a\delta_x e - (1 + a)e \}.
\]

We will compute the difference dimension polynomial associated with the difference scheme (4) using the method described at the end of subsection A. Thus, we consider \(K\) as a difference field with basic set \(\Sigma = \{ \alpha_x : x \mapsto x + 1, \alpha_t : t \mapsto t + 1, \beta_x : x \mapsto x - 1, \beta_t : t \mapsto t - 1 \}\). Let \(\tilde{G} := \{ g_1 := \alpha_t e - a\alpha_x^2 e + 2a\alpha_x e - (1 + a)e, g_2 := \alpha_x \beta_x e - e, g_3 := \alpha_t \beta_t e - e \}\) and \(I = K[\Sigma] \langle \tilde{G} \rangle\). Then \(K[\Sigma]e/I\) is isomorphic \(K[\Delta^*]e/N\) via the isomorphism

\[
\alpha_x^{a_x} \alpha_t^{a_t} \beta_x^{b_x} \beta_t^{b_t} e \mapsto \delta_x^{a_x-b_x} \delta_t^{a_t-b_t} e.
\]

We fix an admissible order \(\prec\) on \([\Sigma]e\) defined by

\[
\alpha_x^{a_x} \alpha_t^{a_t} \beta_x^{b_x} \beta_t^{b_t} e \prec \alpha_x^{c_x} \alpha_t^{c_t} \beta_x^{d_x} \beta_t^{d_t} e \iff
\]
Computation of the Strength

\[(a_x + a_t + b_x + b_t, a_x, a_t, b_x, b_t) <_{\text{lex}} (c_x + c_t + d_x + d_t, c_x, c_t, d_x, d_t)\]

and compute a Gröbner basis of \(I\) with respect to \(<\). The S-polynomial \(S(g_1, g_2)\) of \(g_1\) and \(g_2\) is given by

\[S(g_1, g_2) = -2\alpha_x \beta_x e - \frac{1}{a} \alpha_t \beta_x e + \left(1 + \frac{1}{a}\right) \beta_x e + \alpha_x e\]

and is reducible modulo \(g_2\) to \(-\frac{1}{a} \alpha_t \beta_x e + \left(1 + \frac{1}{a}\right) \beta_x e + \alpha_x e - 2e\), which is irreducible modulo \(\tilde{G}\). Hence, \(g_4 := -\frac{1}{a} \alpha_t \beta_x e + \left(1 + \frac{1}{a}\right) \beta_x e + \alpha_x e - 2e\) should be inserted into \(\tilde{G}\). For \(S(g_1, g_3) = -2\alpha_x \alpha_t \beta_t e - \frac{1}{a} \alpha_t^2 \beta_t e + \left(1 + \frac{1}{a}\right) \alpha_t \beta_t e + \alpha_x e\) we have

\[S(g_1, g_3) \rightarrow_{g_3} -\frac{1}{a} \alpha_t^2 \beta_t e + \alpha_x^2 e + \left(1 + \frac{1}{a}\right) \alpha_t \beta_t e - 2\alpha_x e\]

\[\rightarrow_{g_3} \alpha_x^2 e + \left(1 + \frac{1}{a}\right) \alpha_t \beta_t e - 2\alpha_x e - \frac{1}{a} \alpha_t e\]

\[\rightarrow_{g_1} \left(1 + \frac{1}{a}\right) \alpha_t \beta_t e - \left(1 + \frac{1}{a}\right) e\]

\[\rightarrow_{g_3} 0.\]

Furthermore

\[S(g_1, g_4) = a\alpha_x^3 e + (a + 1) \alpha_x^2 \beta_x e - 2\alpha_x \alpha_t \beta_x e - \frac{1}{a} \alpha_t^2 \beta_x e - 2a\alpha_x^2 e\]

\[+ \left(1 + \frac{1}{a}\right) \alpha_t \beta_x e\]

\[\rightarrow_{g_1} (a + 1) \alpha_x^2 \beta_x e - 2\alpha_x \alpha_t \beta_x e - \frac{1}{a} \alpha_t^2 \beta_x e + \alpha_x \alpha_t e\]

\[+ \left(1 + \frac{1}{a}\right) \alpha_t \beta_x e - (1 + a) \alpha_x e\]

\[\rightarrow_{g_1} -2\alpha_x \alpha_t \beta_x e - \frac{1}{a} \alpha_t^2 \beta_x e + \alpha_x \alpha_t e + (2a + 2) \alpha_x \beta_x e\]

\[+ (2 + 2/a) \alpha_t \beta_x e - (1 + a) \alpha_x e + (-2 - a - 1/a) \beta_x e\]

\[\rightarrow_{g_2} -\frac{1}{a} \alpha_t^2 \beta_x e + \alpha_x \alpha_t e + (2a + 2) \alpha_x \beta_x e + (2 + 2/a) \alpha_t \beta_x e\]

\[- (1 + a) \alpha_x e - 2\alpha_t e + (-2 - a - 1/a) \beta_x e\]

\[\rightarrow_{g_4} (2a + 2) \alpha_x \beta_x e + \left(1 + \frac{1}{a}\right) \alpha_t \beta_x e - (1 + a) \alpha_x e\]

\[+ (-2 - a - 1/a) \beta_x e\]

\[\rightarrow_{g_2} \left(1 + \frac{1}{a}\right) \alpha_t \beta_x e - (1 + a) \alpha_x e + (-2 - a - 1/a) \beta_x e\]

\[+ (2a + 2)e\]

\[\rightarrow_{g_4} 0\]

\[S(g_2, g_3) = \alpha_x \beta_x e - \alpha_t \beta_t e\]
Computation of the Strength

\[ \rightarrow_{g_2} -\alpha_t \beta_t e + e \]
\[ \rightarrow_{g_1} 0 \]
\[ S(g_2, g_4) = a\alpha_x^2 e + (a + 1)\alpha_{x'_x} e - 2a\alpha_x e - \alpha_t e \]
\[ \rightarrow_{g_1} (a + 1)\alpha_{x'_x} e - (1 + a)e \]
\[ \rightarrow_{g_2} 0 \]
\[ S(g_3, g_4) = a\alpha_x \beta_t e + (a + 1)\beta_x \beta_t e - \beta_x e - 2a\beta_t e \]
\[ =: g_5 \]
\[ S(g_1, g_5) = -\left( 1 + \frac{1}{a} \right) \alpha_{x'_x} \beta_t e + \frac{1}{a} \alpha_{x'_x} e - \frac{1}{a} \alpha_t \beta_t e \]
\[ + \left( 1 + \frac{1}{a} \right) \beta_t e \]
\[ \rightarrow_{g_2} \frac{1}{a} \alpha_{x'_x} e - \frac{1}{a} \alpha_t \beta_t e \]
\[ \rightarrow_{g_2} \frac{1}{a} \alpha_t \beta_t e + \frac{1}{a} e \]
\[ \rightarrow_{g_1} 0 \]
\[ S(g_2, g_5) = -\left( 1 + \frac{1}{a} \right) \beta_x^2 \beta_t e + \frac{1}{a} \beta_x^2 e + 2\beta_x \beta_t e - \beta_t e \]
\[ =: g_6 \]

Further computations of the \( S \)-polynomials \( S(g_i, g_6), 1 \leq i \leq 5 \), show that all of them are reducible to 0 modulo \( \{g_1, \ldots, g_6\} \). Hence, a Gröbner basis for \( I \) is given by

\[ \left\{ \begin{array}{l}
{g_1} = \alpha_t e - a\alpha_x^2 e + 2a\alpha_x e - (1 + a)e, \\
{g_2} = \alpha_x \beta_t e - e, \\
{g_3} = \alpha_t \beta_t e - e, \\
{g_4} = -\frac{1}{a} \alpha_t \beta_x e + \left( 1 + \frac{1}{a} \right) \beta_x e + \alpha_x e - 2e, \\
{g_5} = a\alpha_x \beta_t e + (a + 1)\beta_x \beta_t e - \beta_x e - 2a\beta_t e, \\
{g_6} = -\left( 1 + \frac{1}{a} \right) \beta_x^2 \beta_t e + \frac{1}{a} \beta_x^2 e + 2\beta_x \beta_t e - \beta_t e \\
\end{array} \right. \]

Applying Proposition IV.6 we obtain

\[ |\{ \lambda \in [\Sigma]e \mid \text{ord}(\lambda) \leq r, \lambda \text{ is irreducible modulo } G \}| = 5r. \]

for all sufficiently large \( r \). Therefore, the inversive difference dimension polynomial associated with the difference scheme (4) is given by \( \phi(r) = 5r \).
Computation of the Strength

**Difference dimension polynomial for symmetric difference scheme**

In order to obtain a space symmetric difference scheme for the diffusion equation (3) every occurrence of \( \frac{\partial^2 u(x, t)}{\partial x^2} \) and \( \frac{\partial u(x, t)}{\partial t} \) is replaced by \( u(x+1, t) - 2u(x, t) + u(x-1, t) \) and \( u(x, t+1) - u(x, t) \), respectively. We obtain

\[
u(x, t+1) - u(x, t) = a(u(x+1, t) - 2u(x, t) + u(x-1, t)).\quad (5)
\]

Let \( K \) be an inversive difference field with basic set \( \Delta = \{ \delta_x : x \mapsto x+1, \delta_t : t \mapsto t+1 \} \) containing \( a \) and let \( M \) be an inversive difference \( K \)-vector space generated as a left \( K[\Delta^*] \)-module by one generator \( m \) satisfying the defining equation

\[\delta_t m - m = a(\delta_x m - 2m + \delta_x^{-1} m).\]

Then \( M \) is isomorphic to the factor module of a free \( K[\Delta^*] \)-module with free generator \( e \) by its submodule \( N \) generated by

\[G := \{ \delta_t e - a \delta_x e - \delta_x^{-1} e + (2a - 1)e \}.\]

Now consider \( K \) as a difference field with basic set \( \Sigma = \{ \alpha_x : x \mapsto x+1, \alpha_t : t \mapsto t+1, \beta_x : x \mapsto x-1, \beta_t : t \mapsto t-1 \} \). Let \( \tilde{G} := \{ g_1 := \alpha_t e - \alpha_x e - \beta_x e + (2a-1)e, g_2 := \alpha_x \beta_x e - e, g_3 := \alpha_t \beta_t e - e \} \) and \( I =_{K[\Sigma]} \langle \tilde{G} \rangle \). Then \( K[\Sigma]e/I \) is isomorphic to the difference ring \( K[\Delta^*]e/N \) via the isomorphism

\[\alpha_x^{a_x} \alpha_t^{a_t} \beta_x^{b_x} \beta_t^{b_t} e \mapsto \delta_x^{a_x} \delta_t^{a_t} \delta_x^{b_x} \delta_t^{b_t} e.\]

Let us fix an admissible order \( \prec \) on \( [\Sigma]e \) defined by

\[\alpha_x^{a_x} \alpha_t^{a_t} \beta_x^{b_x} \beta_t^{b_t} e < \alpha_x^{c_x} \alpha_t^{c_t} \beta_x^{d_x} \beta_t^{d_t} e : \iff (a_x + a_t + b_x + b_t, a_x, a_t, b_x, b_t) \prec_{\text{lex}} (c_x + c_t + d_x + d_t, c_x, c_t, d_x, d_t)\]

A Gröbner basis of \( I \) is then given by

\[\{ g_1 := a \beta_x^2 \beta_t e - (2a - 1) \beta_x \beta_t e + \beta_x e + a \beta_t e, \quad g_2 := -\frac{1}{a} \alpha_t \beta_x e + \beta_x^2 e - \left( 2 - \frac{1}{a} \right) \beta_x e + e, \quad g_3 := \alpha_t \beta_t e - e, \quad g_4 := a \alpha_x e - a \beta_x e - (2a - 1)e \}.\]

Applying Proposition IV.6 we obtain

\[|\{ \lambda \in [\Sigma]e \mid \text{ord}(\lambda) \leq r, \lambda \text{ is irreducible modulo } G \}| = 4r\]
Computation of the Strength

for all sufficiently large \( r \). Hence, the inversive difference dimension polynomial associated with the difference scheme (5) is given by \( \phi(r) = 4r \).

Thus, the symmetric difference scheme for the diffusion equation has higher strength (that is, smaller dimension polynomial) than the forward scheme, so the symmetric scheme is more preferable from the point of view of strength.

Example IV.8 (Maxwell equations for vanishing free current density and free charge density)

Let \( E = (E_1, E_2, E_3), D = (D_1, D_2, D_3), H = (H_1, H_2, H_3), B = (B_1, B_2, B_3), J_f = (J_1, J_2, J_3) \) and \( \rho_\text{f} \) be functions of \((x, y, z, t)\) that denote electric field strength, electric displacement vector, magnetic field strength, magnetic displacement vector, free current density and free charge density, respectively. With

\[
\nabla := \left( \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right)
\]

Maxwell’s equations in 3 spatial dimensions are given by

\[
\nabla \cdot D = \rho_f, \quad \nabla \cdot B = 0, \quad \nabla \times E + \frac{\partial B}{\partial t} = 0, \quad \text{and} \quad \nabla \times H = J_f + \frac{\partial D}{\partial t}.
\]

Assuming \( J_f = 0 \) and \( \rho_f = 0 \), Maxwell’s equations can be considered as a set of homogeneous linear differential equations.

Differential dimension polynomial

Let \( K \) be a differential field with basic set \( \Delta = \{ \delta_x = \frac{\partial}{\partial x}, \delta_y = \frac{\partial}{\partial y}, \delta_z = \frac{\partial}{\partial z}, \delta_t = \frac{\partial}{\partial t} \} \).

Assuming \( J_f = 0 \) and \( \rho_f = 0 \) Maxwell’s equations give rise to a differential \( K[\Delta] \)-module \( M \) with generators \( e_1, e_2, e_3, d_1, d_2, d_3, h_1, h_2, h_3, b_1, b_2, b_3 \) satisfying

\[
\begin{align*}
\delta_x d_1 + \delta_y d_2 + \delta_z d_3 &= 0 = \delta_x b_1 + \delta_y b_2 + \delta_z b_3, \\
\delta_y e_3 - \delta_z e_2 + \delta_t b_1 &= 0 = \delta_y h_3 - \delta_z h_2 - \delta_t d_1, \\
\delta_z e_1 - \delta_x e_3 + \delta_t b_2 &= 0 = \delta_z h_1 - \delta_x h_3 - \delta_t d_2, \\
\delta_x e_2 - \delta_y e_1 + \delta_t b_3 &= 0 = \delta_x h_2 - \delta_y h_1 - \delta_t d_3.
\end{align*}
\]

Then \( M \) is isomorphic to the factor module of a free \( K[\delta_x, \delta_y, \delta_z, \delta_t] \)-module with free generators \( p_1, \ldots, p_{12} \) by its submodule \( N \) generated by

\[
G = \{ \delta_x p_7 + \delta_y p_8 + \delta_z p_9, \delta_x p_{10} + \delta_y p_{11} + \delta_z p_{12}, \delta_y p_3 - \delta_z p_2 + \delta_t p_{10}, \delta_y p_6 - \delta_z p_5 - \delta_t p_7, \delta_x p_1 - \delta_x p_3 + \delta_t p_{11}, \delta_z p_4 - \delta_x p_6 - \delta_t p_8, \}
\]
Computation of the Strength

$$\delta_x p_2 - \delta_y p_1 + \delta_z p_{12}, \delta_x p_5 - \delta_y p_4 - \delta_z p_9 \}.$$

We define an admissible order $<$ by

$$\delta_x^a \delta_y^b \delta_z^c e_{j_1} \prec \delta_x^b \delta_y^c \delta_z^d e_{j_2} \iff (a_x + a_y + a_z + a_t, j_1, a_x, a_y, a_z, a_t)$$

$$<_{\text{lex}} (b_x + b_y + b_z + b_t, j_2, b_x, b_y, b_z, b_t).$$

Then $G$ is a Gröbner basis and by Proposition IV.6 the differential dimension polynomial associated with Maxwell’s equations for vanishing free current density and free charge density is given by

$$\phi(r) = \frac{1}{4} r^4 + \frac{19}{6} r^3 + \frac{55}{4} r^2 + \frac{137}{6} r + 12.$$

**Difference dimension polynomial for forward difference scheme**

Let $K$ be an inversive difference field with basic set $\Delta = \{\delta_x : x \mapsto x + 1, \delta_y : y \mapsto y + 1, \delta_z : z \mapsto z + 1, \delta_t : t \mapsto t + 1\}$. If we replace every occurrence of $\delta_i$ in $G$ by $\delta_i - 1$, where $i \in \{x, y, z, t\}$, we obtain a set

$$\tilde{G} = \{\delta_x p_7 - p_7 + \delta_y p_8 - p_8 + \delta_z p_9 - p_9,$$

$$\delta_x p_1 - p_10 + \delta_y p_1 - p_{11} + \delta_z p_2 - p_{12},$$

$$\delta_y p_3 - p_3 - \delta_z p_2 - p_2 + \delta_t p_1 - p_{10},$$

$$\delta_y p_6 - p_6 - \delta_z p_5 - p_5 - \delta_t p_7 - p_7,$$

$$\delta_z p_1 - p_1 - \delta_x p_3 - p_3 + \delta_t p_1 - p_{11},$$

$$\delta_z p_4 - p_4 - \delta_x p_6 - p_6 - \delta_t p_8 - p_8,$$

$$\delta_x p_2 - p_2 - \delta_y p_1 - p_1 + \delta_t p_2 - p_{12},$$

$$\delta_z p_5 - p_5 - \delta_y p_4 - p_4 - \delta_t p_9 - p_9\}.$$

associated with Maxwell’s equations for vanishing free current density and free charge density. Applying the Buchberger algorithm we obtain the following 80-element Gröbner basis $G$ of the associated $K[\alpha_x, \alpha_y, \alpha_z, \alpha_t, \beta_x, \beta_y, \beta_z, \beta_t]$-submodule of the free module with free generators $p_1, \ldots, p_{12}$.

$$G = \{\beta_x \beta_y \beta_z p_{12} + \beta_x \beta_y \beta_z p_{11} - \beta_x \beta_y p_{12} + \beta_x \beta_y \beta_z p_{10} - \beta_x \beta_z p_{11} - \beta_y \beta_z p_{10}, \beta_y \beta_z p_{12} - \alpha_x \beta_y \beta_z p_{10} + \beta_y \beta_z p_{11} - \beta_y \beta_z p_{10} - \beta_z p_{11}, \beta_x \beta_y \beta_z p_9 + \beta_x \beta_y \beta_z p_{08} - \beta_x \beta_y p_9 + \beta_x \beta_y \beta_z p_7 - \beta_x \beta_y \beta_z p_{08} - \beta_y \beta_z p_{07}, \beta_y \beta_z p_{07} - \beta_y \beta_z p_{09} - \alpha_x \beta_y \beta_z p_{07} + \beta_y \beta_z p_{08} - \beta_y p_9 + \beta_y \beta_z p_{07} - \beta_z p_8, \beta_y \beta_z \beta_t p_7\}.$$

30
Computation of the Strength

\[- \beta_y \beta_z \beta_t p_6 - \beta_y \beta_z p_7 + \beta_y \beta_z \beta_t p_5 + \beta_z \beta_t p_6 - \beta_y \beta_t p_7 + \alpha_x \beta_y \beta_t p_5 + \beta_y \beta_t p_6 + \beta_y p_7 \]
\[- \beta_y \beta_t p_5 - \beta_y p_6, - \beta_x \beta_z \beta_t p_8 + \beta_x \beta_z \beta_t p_6 + \beta_x \beta_t p_6 + \beta_x \beta_t p_4 - \beta_x \beta_t p_4, \beta_z \beta_t p_8 \]
\[- \beta_x p_8 + \beta_x \beta_t p_6 + \alpha_z \beta_z \beta_t p_4 - \beta_t p_6 - \beta_x \beta_t p_4, \beta_x \beta_t p_9 - \beta_x \beta_t p_9 - \beta_x \beta_t p_5 + \beta_x \beta_t p_4 \]
\[+ \beta_y \beta_t p_5 - \beta_x \beta_t p_4, \beta_x \beta_t p_9 - \alpha_y \beta_z \beta_t p_4 - \beta_x \beta_t p_5 + \beta_x \beta_t p_4 + \beta_t p_5, - \beta_y \beta_t p_10 \]
\[+ \beta_y \beta z p_10 - \beta_y \beta_z \beta_t p_3 + \beta_y \beta_z \beta_t p_2 + \beta_z \beta_t p_3 - \beta_y \beta_t p_2, \beta_y \beta_t p_10 - \beta_y p_10 + \alpha_z \beta_y \beta_t p_2 + \beta_y \beta_t p_3 \]
\[- \beta_y \beta_t p_2 - \beta_t p_3, \beta_x \beta_z \beta_t p_11 - \beta_x \beta_z p_11 - \beta_x \beta_z p_3 + \beta_x \beta_t p_1 - \beta_x \beta_t p_1, - \beta_x \beta_t p_11 + \beta_x \beta_t p_3 + \alpha_z \beta_z \beta_t p_1 - \beta_t p_3 - \beta_x \beta_t p_1 + \beta_x \beta_t p_12 + \beta_x \beta_t p_12 - \beta_x \beta_t p_2 \]
\[+ \beta_x \beta_y \beta_t p_1 + \beta_y \beta_t p_2 - \beta_x \beta_t p_12 + \beta_x \beta_t p_12 - \alpha_y \beta_z \beta_t p_1 - \beta_x \beta_t p_2 + \beta_x \beta_t p_1 + \beta_t p_2, \]
\[- \beta_t p_9 + \beta_t p_9 - \alpha_x \beta_t p_5 + \alpha_y \beta_t p_4 + \beta_t p_5 - \beta_t p_4, - \beta_t p_8 + \alpha_x \beta_t p_6 + \beta_t p_8 - \alpha_z \beta_t p_4 \]
\[+ \beta_t p_4, - \alpha_y \beta_t p_6 - \beta_t p_7 + \alpha_x \beta_t p_5 + \beta_t p_6 + \beta_t p_7 - \beta_t p_5, - \beta_t p_12 + \beta_t p_12 + \alpha_x \beta_t p_2 - \alpha_y \beta_t p_1 \]
\[- \beta_t p_2 + \beta_t p_1, - \beta_t p_11 + \beta_t p_11 - \alpha_x \beta_t p_3 + \beta_t p_3 + \alpha_x \beta_t p_1 - \beta_t p_1, - \beta_t p_10 + \beta_t p_10 + \beta_t p_10 + \alpha_y \beta_t p_3 \]
\[- \alpha_z \beta_t p_2 - \beta_t p_2 + \beta_t p_1, \alpha_y \beta z p_11 - \beta z p_12 + \alpha_x \beta_z p_10 - \beta z p_11 + \beta_t p_12 + \beta_t p_10, \alpha_y \beta_t p_8 - \beta z p_9 \]
\[+ \alpha_x \beta z p_7 - \beta z p_8 + \beta_t p_9 - \beta_t p_7, - \alpha_t p_9 + \beta_t p_9 + \alpha_x \beta p_5 - \alpha_y p_4 - \beta p_4, - \alpha_t p_8 + \beta_t p_8 - \alpha x p_6 \]
\[+ p_6 - \alpha_t p_4 + p_4, - \alpha_t p_7 + \alpha_y p_6 + p_7 - \alpha_x p_5 - p_6 + p_5, \alpha_t p_12 - p_12 + \beta x p_2 - \alpha y p_1 - p_2 \]
\[+ p_1, \alpha t p_11 - p_11 - \alpha x p_3 + p_3 + \alpha z p_1 - p_1, \alpha t p_10 - p_10 + \alpha y p_3 - \alpha z p_2 - p_3 + p_2, \alpha z p_12 \]
\[+ \alpha y p_11 - p_12 + \alpha x p_10 - p_11 - \alpha x p_10, \alpha z p_6 + \alpha y p_8 - \beta p_9 + \alpha x p_7 - p_8 - \beta p_7 \]
\[\cup \{ \alpha_t \beta_j p_j - p_j \mid i \in \{x, y, z, t\}, j \in \{1, \ldots, 12\} \} \]

Applying Proposition IV.6 we obtain that the difference dimension polynomial associated with the forward difference scheme is given by

\[\phi(r) = 4r^4 + 18r^3 + 35r^2 + 31r + 12.\]

Difference dimension polynomial for symmetric difference scheme

Let \( K \) be an inversive difference field with basic set \( \Delta = \{ \delta_x : x \mapsto x + 1, \delta_y : y \mapsto y + 1, \delta_z : z \mapsto z + 1, \delta_t : t \mapsto t + 1 \} \). Using the symmetric difference scheme we replace every occurrence of \( \delta_i \) in \( G \) by \( \frac{1}{2}(\delta_i - \delta_i^{-1}) \) (\( i \in \{x, y, z, t\} \)) and arrive at a set

\[\tilde{G} = \{ \delta_x p_7 - p_7 + \delta_y p_8 - p_8 + \delta_z p_9 - p_9, \]
\[\delta_x p_10 - p_10 + \delta_y p_11 - p_11 + \delta_z p_12 - p_12, \]
\[\delta_y p_3 - p_3 - \delta_z p_2 - p_2 + \delta_t p_10 - p_10, \]
Computation of the Strength

\[
\begin{align*}
\delta_y p_6 - p_6 - \delta_x p_5 - p_5 - \delta_t p_7 - p_7, \\
\delta_z p_1 - p_1 - \delta_x p_3 - p_3 + \delta_t p_{11} - p_{11}, \\
\delta_z p_4 - p_4 - \delta_x p_6 - p_6 - \delta_t p_8 - p_8, \\
\delta_x p_2 - p_2 - \delta_y p_1 - p_1 + \delta_t p_{12} - p_{12}, \\
\delta_x p_5 - p_5 - \delta_y p_4 - p_4 - \delta_t p_9 - p_9. 
\end{align*}
\]

Proceeding as above we obtain that the corresponding difference dimension polynomial is given by

\[
\phi(r) = 4r^4 + \frac{56}{3}r^3 + 36r^2 + 4r + 22.
\]

Comparing difference dimension polynomials computed for the forward and symmetric difference schemes we can conclude that the strength of the system of difference equations obtained via forward difference scheme is higher than the strength of the system obtained with the use of symmetric difference scheme. This time we obtain that the forward scheme is more preferable from the point of view of strength.

Example IV.9 (Equations for electromagnetic field given by potential)

An electromagnetic field can be defined by the differential equations describing its potential, cf. (Ex. 9.2.6.). The corresponding system of PDEs, which involves four unknown functions \(\psi_1(x_1, \ldots, x_4), \ldots, \psi_4(x_1, \ldots, x_4)\), is as follows.

\[
\begin{align*}
\sum_{j=1}^{4} \frac{\partial}{\partial x_j} \psi_j &= 0, \\
\sum_{j=1}^{4} \left( \frac{\partial^2}{\partial x_j^2} \psi_i - \frac{\partial^2}{\partial x_i \partial x_j} \psi_j \right) &= 0.
\end{align*}
\]

Differential dimension polynomial

Let \(K\) be a differential field with basic set \(\Delta = \{\delta_i = \frac{\partial}{\partial x_i} | i = 1, \ldots, 4\}\). Then equations (7) and (6) give rise to a differential \(K[\Delta]\)-module \(M\) with generators \(m_1, \ldots, m_4\) satisfying for \(i = 1, \ldots, 4\) the defining equations

\[
\begin{align*}
\sum_{j=1}^{4} \delta_j m_j &= 0, \\
\sum_{j=1}^{4} (\delta_j^2 m_i - \delta_i \delta_j m_j) &= 0.
\end{align*}
\]
Then \( M \) is isomorphic to the factor module of a free \( K[\Delta] \)-module with free generators \( e_1, \ldots, e_4 \) by its submodule \( N \) generated by
\[
\left\{ \sum_{j=1}^{4} \delta_j e_j \right\} \cup \left\{ \sum_{j=1}^{4} \left( \delta_j^2 e_i - \delta_i \delta_j e_j \right) \middle| i = 1, \ldots, 4 \right\}.
\] (8)

Defining an admissible order \( \prec \) by
\[
\delta_1^a \delta_2^b \delta_3^c \delta_4^d e_{j_1} \prec \delta_1^{a'} \delta_2^{b'} \delta_3^{c'} \delta_4^{d'} e_{j_2} : \iff (a_1 + a_2 + a_3 + a_4, j_1, a_1, a_2, a_3, a_4) <_{\text{lex}} (b_1 + b_2 + b_3 + b_1, j_2, b_1, b_2, b_3, b_4),
\]
we obtain the following Gröbner basis \( G \) for \( N \).
\[
G = \{ \delta_1^2 e^3 + \delta_2^2 e^3 + \delta_3^2 e^3 + \delta_4^2 e^3 \\
\delta_1^2 e^2 + \delta_2^2 e^2 + \delta_3^2 e^2 + \delta_4^2 e^2 \\
\delta_1^2 e + \delta_2^2 e + \delta_3^2 e + \delta_4^2 e \\
\delta_1 e + \delta_2 e^2 + \delta_3 e^3 + \delta_4 e^4 \\
\delta_1^2 e^4 - \delta_1 \delta_4 e + \delta_2^2 e^4 - \delta_2 \delta_4 e^2 + \delta_3^2 e^4 - \delta_3 \delta_4 e^3 \}\.
\]

Applying Proposition IV.6 we obtain that the differential dimension polynomial associated with (7) and (6) is given by
\[
\phi(r) = r^3 + \frac{11}{2} r^2 + \frac{17}{2} r + 4.
\]

Difference dimension polynomial for forward difference scheme

Let \( K \) be an inversive difference field with basic set \( \Delta = \{ \delta_i : x_i \mapsto x_i + 1 \mid i = 1, \ldots, 4 \} \). Replacing every occurrence of \( \delta_k \) in (8) by \( \delta_k - 1 \ (k = 1, \ldots, 4) \) we obtain that the desired dimension polynomial is the \( \Delta^* \)-dimension polynomial associated with the factor module of the free \( K[\Delta^*] \)-module \( E = \sum_{i=1}^{4} K[\Delta^*] e_i \) by its \( K[\Delta^*] \)-submodule generated by the set
\[
\left\{ \sum_{j=1}^{4} \delta_j e_{j} - e_j \right\} \cup \left\{ \sum_{j=1}^{4} \left( \delta_j^2 e_i - 2 \delta_j e_i + e_i - \delta_i \delta_j e_j + \delta_i e_j + \delta_j e_j - e_j \right) \middle| i = 1, \ldots, 4 \right\}.
\]
Computation of the Strength

Exploring the idea described at the end of subsection A, let us consider $K$ as a difference field with basic set

$$\Sigma = \{ \alpha_i : x_i \mapsto x_i + 1, \beta_i : x_i \mapsto x_i - 1 \mid i = 1, \ldots, 4 \}$$

and let the admissible order $\prec$ be given by

$$\alpha_1^{a_1} \alpha_2^{a_2} \alpha_3^{a_3} \alpha_4^{a_4} \beta_1^{b_1} \beta_2^{b_2} \beta_3^{b_3} \beta_4^{b_4} e_i \prec \alpha_1^{c_1} \alpha_2^{c_2} \alpha_3^{c_3} \alpha_4^{c_4} \beta_1^{d_1} \beta_2^{d_2} \beta_3^{d_3} \beta_4^{d_4} e_j$$

$$\iff (a_1 + b_1 + \cdots + a_4 + b_4, i, a_1, \ldots, a_4, b_1, \ldots, b_4) <_{\text{lex}} (c_1 + d_1 + \cdots + c_4 + d_4, i, c_1, \ldots, c_4, d_1, \ldots, d_4).$$

Using the Maple package "Ore-Algebra" for computing a Gröbner basis of the $K[\Sigma]$-submodule generated by

$$\left\{ \sum_{j=1}^{4} \alpha_j e_j - e_j \right\} \cup$$

$$\left\{ \sum_{j=1}^{4} (\alpha_j^2 e_i - 2 \alpha_j e_i + e_i - \alpha_i \alpha_j e_j + \alpha_i e_j + \alpha_j e_j - e_j) \mid i = 1, \ldots, 4 \right\}$$

we obtain the set of leading terms of the Gröbner basis

$$\{ \alpha_4 \beta_8 e_1, \alpha_3 \beta_7 e_1, \alpha_2 \beta_6 e_1, \alpha_1 \beta_5 e_1, \alpha_1 \beta_8 e_1, \alpha_2 \beta_5 e_1, \alpha_2 \beta_8 e_1, \alpha_1 \beta_6 e_1 \}$$

Applying Proposition IV.6 we compute the difference dimension polynomial associated with a forward difference scheme for (7) and (6) to be

$$\phi(r) = 15r^3 - \frac{7}{2}r^2 + \frac{43}{2}r^2 + 2.$$

Difference dimension polynomial for symmetric difference scheme
Let $K$ be an inversive difference field with basic set $\Delta = \{\delta_i : x_i \mapsto x_i + 1 \mid i = 1, \ldots, 4\}$. Replacing every occurrence of $\delta_k$ in (8) by $\frac{1}{2}(\delta_k - \delta_k^{-1})$ ($k = 1, \ldots, 4$) we obtain the set

$$
\left\{ \sum_{j=1}^{4} \frac{1}{2}(\delta_j - \delta_j^{-1})e_j \right\} \cup \\
\left\{ \sum_{j=1}^{4} \frac{1}{4}(\delta_j^2e_i - 2e_i + \delta_j^{-2}e_i \\
- \alpha_i \delta_j e_j + \beta_i \delta_j^{-1}e_j + \delta_i^{-1} \delta_j e_j - \delta_i^{-1} \delta_j^{-1}e_j) \mid i = 1, \ldots, 4 \right\},
$$

which generates a $K[\Delta^*]$-submodule $N$ of the free $K[\Delta^*]$-module $M = \sum_{i=1}^{4} K[\Delta^*]e_i$ such that the difference dimension polynomial of our system of difference equations is the $\Delta^*$-dimension polynomial of $M/N$.

Using the approach described at the end of subsection A, we treat $K$ as a difference field with basic set

$$
\Sigma = \{\alpha_i : x_i \mapsto x_i + 1, \beta_i : x_i \mapsto x_i - 1 \mid i = 1, \ldots, 4\}
$$

and consider the admissible order $\prec$ given by

$$
\alpha_1^{a_1} \alpha_2^{a_2} \alpha_3^{a_3} \alpha_4^{a_4} \beta_1^{b_1} \beta_2^{b_2} \beta_3^{b_3} \beta_4^{b_4} e_i \prec \alpha_1^{c_1} \alpha_2^{c_2} \alpha_3^{c_3} \alpha_4^{c_4} \beta_1^{d_1} \beta_2^{d_2} \beta_3^{d_3} \beta_4^{d_4} e_j \\
\iff (a_1 + b_1 + \cdots + a_4 + b_4, i, a_1, \ldots, a_4, b_1, \ldots, b_4) \\
<_{\text{lex}} (c_1 + d_1 + \cdots + c_4 + d_4, i, c_1, \ldots, c_4, d_1, \ldots, d_4).
$$

Once again using the Maple package “Ore-Algebra” for computing a Gröbner basis of the $K[\Sigma]$-submodule generated by

$$
\left\{ \sum_{j=1}^{4} \frac{1}{2}(\alpha_j - \beta_j)e_j \right\} \cup \\
\left\{ \sum_{j=1}^{4} \frac{1}{4}(\alpha_j^2e_i - 2e_i + \alpha_j^{-2}e_i \\
- \alpha_i \alpha_j e_j + \alpha_i \beta_j e_j + \beta_i \alpha_j e_j - \beta_i \beta_j e_j) \mid i = 1, \ldots, 4 \right\}
$$

we obtain the set of leading terms of the Gröbner basis

$$\{\alpha_4 \beta_8 e_1, \alpha_3 \beta_7 e_1, \alpha_2 \beta_6 e_1, \alpha_1 \beta_5 e_1, \alpha_1^2 e_1, \alpha_4 \beta_8 e_2, \alpha_2^2 \beta_5 e_1, \alpha_3 \beta_7 e_2, \ldots\}.
Computation of the Strength

\[
\begin{align*}
\alpha_2 \beta_6 e_2, & \quad \alpha_1 \beta_5 e_2, \quad \alpha_1^2 e_2, \quad \alpha_4 \beta_8 e_3, \quad \beta_2^2 e_4, \quad \alpha_2^2 \beta_5 \beta_6 e_1, \quad \alpha_2^2 \beta_5 e_2, \quad \alpha_3 \beta_7 e_3, \\
\alpha_2 \beta_6 e_3, & \quad \alpha_1 \beta_5 e_3, \quad \alpha_1^2 e_3, \quad \alpha_4 e_4, \quad \beta_3^2 \beta_6 \beta_7 \beta_8 e_1, \quad \alpha_2^2 \beta_5 \beta_6 \beta_7 e_1, \quad \alpha_2^2 \beta_5 \beta_6 e_2, \\
\alpha_2^2 \beta_5 e_4, & \quad \alpha_3 \beta_7 e_4, \quad \alpha_2 \beta_6 e_4, \quad \alpha_1 \beta_5 e_4, \quad \alpha_1^2 e_4, \quad \beta_3^2 \beta_6 \beta_7 \beta_8 e_2, \quad \alpha_2^2 \beta_5 \beta_6 \beta_7 e_2, \\
\alpha_2^3 \beta_5 \beta_6 e_3, & \quad \alpha_2^3 \beta_5 e_4, \quad \beta_3^3 \beta_6 \beta_7 \beta_8 e_3, \quad \alpha_4 \beta_5 \beta_6 \beta_7 e_3, \quad \alpha_2^3 \beta_5 \beta_6 e_4, \quad \beta_3^3 \beta_6 \beta_7 e_4 
\end{align*}
\]

Applying Proposition IV.6 we compute the difference dimension polynomial associated with a symmetric difference scheme for (7) and (6) to be

\[
\phi(r) = 16r^3 - 8r^2 + 24r + 8.
\]

Comparing difference dimension polynomials computed for the forward and symmetric difference schemes we see that in this case, as in the previous example, the forward scheme is more preferable from the point of view of strength.

CONCLUSION

We have developed a method for evaluation of the strength of systems of partial differential and difference equations based on the computation of the corresponding differential and difference dimension polynomials. We have also presented algorithms for such computation that extend the Gröbner basis technique to the cases of differential, difference, and inversive difference modules. Finally, we have determined the strength of some fundamental systems of PDEs of mathematical physics and the strength of the corresponding systems of partial difference equations obtained by the forward and symmetric difference schemes.
