Abstract. An outline of the basic Riemannian structures underlying the separation of
variables in the Hamilton–Jacobi equation of natural Hamiltonian systems.

Key words: Riemannian geometry; Hamilton–Jacobi equation; separation of variables

2010 Mathematics Subject Classification: 70H20; 35F21; 58B21

This paper was submitted to the Royal Society and accepted for publication in a special
volume dedicated to the State of the Art of the Separation of Variables (2004). However,
this volume was never published due to the sudden death of the Editor, Vadim Kuznetsov,
to whom I dedicate this work.

1 Introduction

In the past years the study of separable systems (whose Hamilton–Jacobi equations can be
integrated by separation of variables) has shown a remarkable development, also in relation
with other kinds of integrable systems (bi-Hamiltonian systems, Lax systems). I think that
an outline of the Riemannian background of this theory may be useful for specialists as well
as beginners. With the exception of the last section, we will confine our discussion to the
orthogonal separable systems (called Stäckel systems) and to a special class of Stäckel systems,
referred to as L-systems. Some of the theorems presented here are new. For some of the recalled
theorems a new shorter proof is provided. Let $Q$ be an $n$-dimensional Riemannian manifold with
generic local coordinates $q = (q^i)$ and (contravariant) metric tensor $G = (g^{ij})$, which we assume
to be positive-definite, and let $T^*Q$ be the cotangent bundle of $Q$, with canonical coordinates
$(\bar{q}, \bar{p}) = (q^i, p_i)$. We will deal with the additive separation of the Hamilton–Jacobi equations

$$G(q, p) = E, \quad H(q, p) = E, \quad p_i = \frac{\partial}{\partial q_i} W,$$

where $G = \frac{1}{2} g^{ij} p_i p_j$ is the geodesic Hamiltonian on $T^*Q$, and $H = G + V = \frac{1}{2} g^{ij} p_i p_j + V$ is
a natural Hamiltonian, $V(q)$ being the potential energy, a smooth function on $Q$ canonically lifted
to a function on $T^*Q$. A coordinate system $q$ is called separable if the geodesic Hamilton–Jacobi
equation $G = E$ admits a complete solution of the form

$$W(q, \xi) = \sum_{i=1}^n W_i(q^i, \xi_i), \quad \xi = (\xi^i), \quad \text{det} \left[ \frac{\partial^2 W}{\partial q^i \partial \xi^j} \right] \neq 0. \quad (1.1a)$$

arXiv:1512.07833v2 [math-ph] 1 Feb 2016
Such a solution is called separated solution. Also note, that in these definitions the presence of a set of $n$ constants $q$ satisfying the completeness condition (1.1b) is fundamental. Note that here we consider only natural canonical coordinates, where $q$ are coordinates on the configuration manifold. Levi-Civita [37] proved that a Hamilton–Jacobi equation $H(q,p) = E$ admits a separated solution (1.1) if and only if the differential equations

$$L_{ij}(H) = \partial_i H \partial_j H \partial^i \partial^j H + \partial^i H \partial^j \partial_i \partial_j H - \partial_i H \partial^j \partial_j \partial^i H - \partial^i H \partial_j \partial_i \partial^j H = 0$$

are identically satisfied. These are known as the separability conditions or separability equations of Levi-Civita. They provide not only a simple method for testing whether a coordinate system is separable or not, but also the basis for the geometrical (i.e., intrinsic) characterisation of the separation. A first (and well known) example of application is the following: the Levi-Civita equations for a natural Hamiltonian,

$$L_{ij}(G+V) = 0,$$

are equivalent to equations

$$S_{ij}(g^{kk}) = 0, \quad S_{ij}(V) = 0. \quad (1.3)$$

where $S_{ij}()$ denote the Stäckel operators associated with an orthogonal metric ($g^{ii}$). For any smooth function $V$ on $Q$, it is defined by

$$S_{ij}(V) = \partial_i \partial_j V - \partial_i \ln g^{ij} \partial_j V - \partial_j \ln g^{ii} \partial_i V, \quad i \neq j.$$

The Levi-Civita equations $L_{ij}(G+V) = 0$ are equivalent to equations

$$S_{ij}(g^{kk}) = 0, \quad S_{ij}(V) = 0. \quad (1.3)$$

2 Killing tensors

As shown by Eisenhart [26, 27] (for the orthogonal case) and by Kalnins and Miller [32, 33], the geodesic separation is related to the existence of Killing vectors and Killing tensors of order two. In this section we recall the basic properties of these objects. The contravariant symmetric tensors $K = (K^{i\cdots j})$ on $Q$ are in one-to-one correspondence with homogenous polynomials on $T^*Q$,

$$K = (K^{i\cdots j}) \leftrightarrow P_K = P(K) = K^{i\cdots j}p_i \cdots p_j.$$ 

For a tensor of order zero, i.e., a function $f$ on $Q$, we define $P_f = f$, where $f$ is canonically lifted to $T^*Q$ (by constant values on the fibers). The space of these polynomial functions is closed with respect to the canonical Poisson bracket

$$\{A, B\} = \partial^i A \partial_i B - \partial^i B \partial_i A.$$ 

$\dagger$ Notation: $\partial_i = \partial/\partial q^i$, $\partial^i = \partial/\partial p_i$. 

---
Hence, on the space of the symmetric contravariant tensors we define a Lie-algebra structure $[\cdot, \cdot]$ by setting

$$P([K_1, K_2]) = \{P(K_1), P(K_2)\},$$

and the symmetric product $\odot$ by setting

$$P(K_1 \odot K_2) = P(K_1) \cdot P(K_2).$$

Note that all the above-given definitions do not depend on a metric tensor. If a metric tensor $G$ is present, then we say that $K$ is a Killing tensor (KT) if $P(K)$ is in involution with $P(G) = 2G$,

$$\{P(K), P(G)\} = 0 \iff [K, G] = 0. \quad (2.1)$$

This means that $P(K)$ is a first integral of the geodesic flow. In the special case of a function $f$, this definition is equivalent to $\nabla f = 0$ (by $\nabla f$ we denote the gradient of a function $f$). A vector field $X$ is a Killing vector, $[X, G] = 0$, if and only if its flow preserves the metric.

Let us consider the case of a symmetric 2-tensor $K$. Since a metric tensor is present, the boldface object $K$ can be represented in components as a tensor of type $(2, 0)$, $(1, 1)$ and $(0, 2)$, respectively, $K = (K^{ij}) = (K^i_j) = (K_{ij}).$

As a symmetric tensor of type $(1, 1)$, $K$ defines an endomorphism on the space $\mathcal{X}(Q)$ of the (smooth) vector fields on $Q$ and an endomorphism on the space $\Phi^1(Q)$ of the (smooth) 1-forms on $Q$. We will denote by $KX$ the vector field image of $X \in \mathcal{X}(Q)$ by $K$, and by $K \phi$ the 1-form image of $\phi \in \Phi^1(Q)$ by $K$. This means that $KX = K^j_i X^i \partial_i$, $K\phi = K^i_j \phi_i dq^j$. Note that the metric tensor $G$ coincide with the identity operator $I$, whose $(1, 1)$ components are given by the Kronecker symbol $\delta^i_j$. Then a 2-tensor $K$ gives rise to eigenvalues, eigenvectors or eigenforms, according to equations $KX = \rho X$, $K\phi = \rho \phi$. We recall that, in a positive-definite metric,

(i) all symmetric tensors have real eigenvalues; (ii) the algebraic multiplicity of an eigenvalue $\rho$ (i.e., its order as a root of the characteristic equation $\det(K - \rho G) = 0$) is equal to its geometrical multiplicity (i.e., the dimension of the space of the corresponding eigenvectors, or eigenforms); the eigenspaces corresponding to distinct eigenvalues are orthogonal. We will denote by $K_1 K_2$ the product of the two endomorphisms $K_1$ and $K_2$; in components $(K_1 K_2)^{ij} = K_1^{ih} K_2^{hj}$. The algebraic commutator of the two tensors will be denoted by

$$[K_1, K_2] = K_1 K_2 - K_2 K_1.$$ 

If a symmetric 2-tensor $K$ can be diagonalised in orthogonal coordinates, $K^{ij} = 0$ for $i \neq j$, then $K^{ii} = \rho^i g^{ii}$, where $(\rho^i)$ are the eigenvalues of $K$. By writing the Killing equation (2.1) in these coordinates, we see that $K$ is a KT if and only if equations

$$\partial_i \rho^j = (\rho^i - \rho^j) \partial_i \ln g^{ij}. \quad (2.2)$$

are satisfied by the eigenvalues. These equations have been called Killing–Eisenhart equations in [13] since they have been extensively used by Eisenhart [27]. However, they appear in an earlier paper by Levi-Civita [36, p. 285].

3 Killing–Stäckel spaces

Equations (2.2) can be interpreted as a linear system of $n$ first-order partial differential equations in normal form, in the $n$ unknown functions $\rho^i(q)$. It is a remarkable fact that the integrability conditions assume of the form

$$(\rho^i - \rho^j) S_{ij}(g^{kk}) = 0.$$
Then their link with the orthogonal separability is at once clear. A second, and even more remarkable property, is that the unknown functions \( \rho^i \) appear in the integrability conditions through their differences \( \rho^i - \rho^j \). This means that if the system (2.2) admits a solution such that \( \rho^i \neq \rho^j \), then it is completely integrable. Note that for a linear system the converse is always true. Going back to the orthogonal separability conditions (1.2) we can immediately conclude that: (I) a system of orthogonal coordinates is separable if and only if there exists a KT which is diagonalised in these coordinates and which has pointwise simple eigenvalues. Furthermore, since the system (2.2) is linear, if it is completely integrable then it admits a \( n \)-dimensional space of solutions (and its converse). As a consequence: (II) a Killing tensor \( K \) which has simple eigenvalues and is diagonalised in orthogonal coordinates generates a \( n \)-dimensional space \( K \) of Killing tensors which are all diagonalised in the same coordinates. Such a space will be called Killing–Stäckel space (KS-space). In the space of direct sums of Killing tensors, \( K = c \oplus K_1 \oplus K_2 \oplus \cdots \oplus K_n \oplus \cdots \) endowed with the Lie bracket \([\cdot,\cdot]\) defined above, a KS-space, which is made of elements \( 0 \oplus 0 \oplus K_2 \oplus 0 \oplus \cdots \), is an involutive subalgebra. For this reason it has also been called Killing–Stäckel algebra in [13, 14].

Three remarks are in order: (i) the metric tensor belongs to any KS-space – indeed, \( \rho^i = 1 \) is a trivial solution of the system (2.2); (ii) if two KS-spaces have an element with simple eigenvalues in common, then they coincide; (iii) all elements of a KS-space are in involution (if equations (2.2) are satisfied for two tensors \( K_1 \) and \( K_2 \), then \( \{ P(K_1), P(K_2) \} = 0 \)).

All the above properties have a local character and are related to a coordinate system. We remark, however, that they are more precisely related to an equivalence class of orthogonal systems, being equivalent to two systems of coordinates \( q \) and \( q' \) simply related by a separated transformation or a rescaling: \( q^i = q'^i(\rho^i) \).

We look for a coordinate-free description of all this matter. To this end we recall some basic concepts.

A frame on a differentiable manifold \( Q \) (not necessarily Riemannian) is a set of vector fields \( (X_i) \) which form a basis of the tangent space \( T_qQ \) at each point \( q \) of their domain of definition. In general, frames exist only locally. Global frames are defined if and only if the manifold is parallelisable, i.e., when \( TQ \simeq Q \times \mathbb{R}^n \). Two frames \( (X_i) \) and \( (X'_i) \) are said to be equivalent if there are nowhere vanishing functions \( f_i \) such that \( X_i = f_iX'_i \). A frame is called holonomic or integrable if it is equivalent to a natural frame \( (\partial_t) \) associated with coordinates \( (\rho^i) \). A basic property is (cf. [49] and [13])

**Theorem 3.1.** The three following conditions are equivalent: (i) the frame \( (X_i) \) is holonomic, (ii) for each pair of indices \( (i,j) \) the distribution spanned by the vectors \( X_i \) and \( X_j \) is completely integrable, (iii) for each index \( i \) the distribution spanned by the \( n-1 \) vectors \( X_j \) for \( j \neq i \) is completely integrable.

On a Riemannian manifold a vector field \( X \) is called normal if it is orthogonally integrable or surface forming, i.e., if it is orthogonal to a family of hypersurfaces. In a positive-definite metric a symmetric tensor \( K \) with simple eigenvalues and normal eigenvectors gives rise to and equivalence class of holonomic orthogonal frames hence, to an equivalence class of orthogonal coordinates. Then we get the following simple intrinsic characterisation of the orthogonal geodesic separation [32, Corollary 4, Section 3] (see also [6]):

**Theorem 3.2.** The geodesic Hamilton–Jacobi equation is separable in orthogonal coordinates if and only if there exists a Killing 2-tensor with simple eigenvalues and normal eigenvectors.

A KT having these properties will be called a characteristic Killing tensor (ChKT). The eigenvectors generates a family of \( n \) orthogonal foliations of manifolds of codimension 1, which we call Stäckel web. Any coordinate system \( (q^i) \) such that the web is locally described by equations \( q^i = \text{const} \) (this is equivalent to say that \( dq^i \) are eigenforms of the ChKT), is separable.
In accordance with the remarks above, a ChKT generates a KS-space. A suitable coordinate-independent definition of this concept is the following: a St"ackel space on a Riemannian manifold $Q_n$ is a $n$-dimensional linear space $K_n$ of Killing 2-tensors whose elements (a) commute as linear operators, $[K_1, K_2] = 0$, and (b) are in involution, $[K_1, K_2] = 0$. Indeed, in the algebraic realm it can be proved that in such a space there exists an element with pointwise distinct eigenvalues (in the neighborhood of any given point of the domain of definition of $K_n$); as a consequence, the commutation relation (a), applied to such a tensor $K_1$, shows that all elements have common eigenvectors. Furthermore, from (b) it follows that

**Theorem 3.3.** If $n$ independent KT’s in involution have the same eigenvectors, then these eigenvectors are normal.

This remarkable property was firstly discovered by Kalnins and Miller [32]. However, it is also a remarkable fact that in this last theorem the assumption that the independent tensors are KTs is redundant. In fact, it can be proved that

**Theorem 3.4.** An orthogonal frame made of common eigenvectors of $n$ independent symmetric 2-tensors in involution is holonomic (the eigenvectors are normal).

For a detailed discussion and proof see [13]. As a consequence, we have a second intrinsic characterisation of the orthogonal geodesic separation (compare with [32, Theorem 6, Section 3] and [50]; note that in [32, Theorem 6(4)] turns out to be redundant):

**Theorem 3.5.** The geodesic Hamilton–Jacobi equation is separable in orthogonal coordinates if and only if the Riemannian manifold admits a KS-space, i.e., a $n$-dimensional linear space $K$ of Killing tensors commuting as linear operators and in involution.

In the applications, one of these last two theorems can be used according to the convenience. By applying Theorem 3.2 we have the advantage of dealing with a single KT, but difficulties may arise in testing if it has simple eigenvalues and normal eigenvectors. Nevertheless, for solving this problem we can use the following two effective criteria:

**Theorem 3.6.** A $(1, 1)$ tensor $K$ has distinct eigenvalues if and only if

$$D = \begin{vmatrix} n & S_1 & \ldots & S_{n-1} \\ S_1 & S_2 & \ldots & S_n \\ \vdots & \vdots & \ldots & \vdots \\ S_{n-1} & S_n & \ldots & S_{2n-2} \end{vmatrix} \neq 0, \quad S_p = \text{tr} (K^p).$$

Here $K^p$ is the power $p = 0, 1, 2, \ldots$ of the linear mapping $K$. This theorem is a consequence of a classical theorem of Sylvester about the discriminant $D$ of an algebraic equation, here applied to the characteristic equation of $K$.

**Theorem 3.7.** A symmetric tensor $K$ with simple eigenvalues has normal eigenvectors if and only if

$$H^h_{ab} K^a_i K^b_j + 2H^b_{a[i} K^a_{j]} K^h + H^a_{ij} K^b K^a = 0,$$

where $H$ is the Nijenhuis torsion of $K$,

$$H^h_{ij}(K) = 2K^a_{[i} \partial_{[a} K^h_{j]} - 2K^h_{a[i} \partial_{[i} K^a_{j]}. $$

This is a special case of a more general theorem due to Haantjes [29] (see also [49, p. 248]). As will be seen in Section 7, it is interesting the case of a torsionless tensor: $H(K) = 0$. We will apply the following
Theorem 3.8 ([45]). A symmetric tensor $K$ with simple eigenvalues $\rho^i$ is torsionless if and only if it has normal eigenvectors $X_i$ such that

$$X_i \rho^j = 0, \quad i \neq j.$$ 

This means that each eigenvalue $\rho^j$ is constant on the hypersurfaces orthogonal to the corresponding eigenvector $X_j$. It is worthwhile to observe that

Theorem 3.9. A torsionless KT with simple eigenvalues is necessarily a constant KT on a flat Riemannian manifold.

Proof. If $H(K) = 0$, then equations (2.2) imply

$$0 = \partial_i \rho^j = (\rho^i - \rho^j) \partial_i \ln g^{ij}, \quad i \neq j, \quad \partial_i \rho^i = 0.$$ 

This shows that $\rho^i = \text{const}$ and that $\partial_i g^{ij} = 0$ for $i \neq j$. This last condition means that $g^{ij}$ is a function of $q^j$ only. In this case, up to a change of scale of the coordinates, we can consider $g^{jj} = \text{const.}$ ■

This is a case considered in [21]. Going back to Theorem 3.5, it is interesting to make a comparison with the intrinsic characterisations of the geodesic orthogonal separation due to Eisenhart [26, 27] and Woodhouse [58]. In the Eisenhart theorem [26, p. 289] the necessary and sufficient conditions for the orthogonal separation are: (i) the existence of $n - 1$ independent Killing tensors $K_1, \ldots, K_{n-1}$ with normal common eigenvectors and such that (ii) for each of these tensors the eigenvalues are simple and (iii) for any pair $(i, \alpha)$ of fixed indices $(\alpha = 2, \ldots, n, \ i = 1, \ldots, n)$ the square matrices $\|\rho^\alpha_i - \rho^\alpha_j\|$ (with $j \neq i$) are regular. In the Eisenhart notation, $\rho^\alpha_i$ are the eigenvalues of $K_{\alpha}$. Condition (i) should be replaced by the existence of $n - 1$ Killing tensors such that $G, K_1, \ldots, K_{n-1}$ are independent. Then Theorem 3.5 shows that conditions (ii) and (iii) are redundant. In [58, Theorem 4.2] the $n - 1$ KT’s are assumed to be in involution and with common closed eigenforms. Theorem 3.3 shows that the requirement closed is redundant, since it is equivalent to the normality of the eigenvectors.

4 The orthogonal separation of a natural Hamiltonian

With each symmetric 2-tensor $K$ and a function $U$ on $Q$ we associate the function $F = \frac{1}{2} P_K + U$ on $T^* Q$. We observe that $F$ is a first integral of $H = G + V$, $\{H, F\} = 0$, if and only if

$$\{G, P_K\} = 0, \quad dU = K \, dV.$$ 

The first equation means that $K$ is a Killing tensor. If it is a ChKT, then, in any orthogonal coordinate system determined by its eigenvectors, the second equation is equivalent to $\partial_i U = \rho^i \partial_i V$. Due to the fundamental equations (2.2), the integrability conditions of these equations assume the form $\partial_j \partial_i U - \partial_i \partial_j U = (\rho^i - \rho^j) S_{ij}(V) = 0$. This proves

Theorem 4.1. If $K$ is a symmetric 2-tensor with simple eigenvalues and normal eigenvectors, then $F$ is a first integral of $G + V$ if and only if $K$ is a Killing tensor and $S_{ij}(V) = 0$ in any orthogonal system of coordinates generated by the eigenvectors.

Since the existence of coordinates is a local matter, condition $dU = K \, dV$ can be replaced by $d(K \, dV) = 0$. Thus, by recalling Theorem 3.2 and the remarks at the end of Section 1, we find that
Theorem 4.2 ([6]). The Hamilton–Jacobi equation \( G + V = E \) is separable in orthogonal coordinates if and only if there exists a Killing 2-tensor \( K \) with simple eigenvalues and normal eigenvectors such that

\[
d(K dV) = 0. \tag{4.1}
\]

This equation has been called characteristic equation of a separable potential \( V \). We observe that for \( n = 2 \) any vector field is normal. Since it can be proved that on a two-dimensional manifold the separation always occurs in orthogonal coordinates [37], we get

Theorem 4.3. On a two-dimensional Riemannian manifold the Hamilton–Jacobi equation \( G + V = E \) is separable if and only if there exists a (non-trivial) quadratic first integral.

This is the extension to a two-dimensional manifold of the so-called Bertrand–Darboux–Whittaker theorem for the Euclidean plane \( \mathbb{E}_2 \) [1, 57].

When written in Cartesian coordinates on a Euclidean \( n \)-space, equation (4.1) gives rise to the so-called Bertrand–Darboux (BD) equations. If we know the form of all characteristic tensors of a manifold, then equation (4.1), written in any coordinate system (even not separable), provides an effective criterion for the separability of the Hamilton–Jacobi equation. This criterion have been applied for instance in the study of the super-separability of the inverse-square three-dimensional Calogero system [11]. In [11] you can find the intrinsic (i.e., “boldface”) expressions of all the characteristic Killing 2-tensors in the Euclidean three-space \( \mathbb{E}_3 \), so that this criterion is ready to be used for any potential \( V \). For a general \( \mathbb{E}_n \), the basic ChKT’s and the corresponding BD equations have been determined in Marshall and Wojciechowski, and in [4, 6]. This analysis has been completed by Waksjö [55]. In his thesis he presents an effective general criterion for the separability of a potential \( V \) in the Euclidean \( n \)-space (see also [56]). Other separability criteria can be based on the analysis of the fundamental invariants of spaces of Killing tensors under the action of isometry groups and the method of moving frames (see [24, 42], also for related references).

If in \( \mathbb{E}_n \) we take

\[
K = \text{tr}(L)G - L, \quad L = A + m r \otimes r + w \otimes r, \tag{4.2}
\]

where \( A \) is symmetric and constant, \( m \in \mathbb{R} \), \( w \) is a constant vector, and \( r \) is the vector representing the generic point, then in Cartesian coordinates \((x^i)\) equation (4.1) yields the Bertrand–Darboux equations (3.25) in [55]. The correspondence of notation is the following: \( A = (\gamma_{ij}) \), \( m = \alpha \), \( w = (2\beta_i) \).

For \( w = 0 \) we get the BD equations for the separation in elliptic coordinates centered at the origin. For \( m = 0 \) we get the BD equations for the separation in parabolic coordinates centered at the point \( P \), where \( L_P(w) \) (the existence of such a point is proved in [4]). For \( w = 0 \) and \( m = 0 \) we have the separation in Cartesian coordinates. In the remaining case \( w \neq 0 \) and \( m \neq 0 \), we have the separation in elliptic coordinates centered at the point \( c = -\frac{1}{2m} w \) (see below).

It must be emphasised that in the characteristic equation (4.1) for a separable potential \( V \) the eigenvalues of \( K \) must be simple (outside a singular set). For the present case we have

Theorem 4.4. The tensor \( K \) defined in (4.2) has simple eigenvalues if and only if for \( m = 0 \) the eigenvalues of \( A \) are simple and for \( m \neq 0 \) the eigenvalues of \( A - \frac{1}{4m} w \otimes w \) are simple.

This is (a slightly modified version of) a theorem of Waksjö [55, p. 45]. We give here an alternative proof.

Proof. The tensor \( K \) has simple eigenvalues if and only if \( L \) has simple eigenvalues. For \( m = 0 \) we have \( L = A + w \otimes r \); we are in the case of the parabolic web [4] and \( L \) has simple eigenvalues
if and only if \( A \) has simple (constant) eigenvalues. For \( m \neq 0 \), let us change the origin by considering the transformation \( r = c + r' \), where \( c \) is a constant vector. We obtain

\[
L = A + m(r' \otimes r' + 2r' \otimes c + c \otimes c) + w \otimes c + w \otimes r'.
\]

If we take \( c = -\frac{1}{2m}w \), then

\[
L = A - \frac{1}{4m}w \otimes w + mw' \otimes r' = A' + mw' \otimes r'.
\]

We known that for a symmetric tensor of the kind \( A' + r' \otimes r' \) the eigenvalues \((u^i)\) are the roots of equation

\[
\sum_i \frac{x_i^2}{u - a^i} = \frac{1}{m},
\]

where \((x_i)\) are Cartesian coordinates and \((a^i)\) are the constant eigenvalues of \( A' \). This equation is equivalent to

\[
m \sum_i x_i^2 \prod_{k \neq i} (u - a^k) - \prod_j (u - a^j) = 0.
\]

If \((a^i)\) are simple, then also \((u^i)\) are simple, since \( a^1 < u^1 < a^2 < u^2 < \ldots < u^{n-1} < a^n < u^n \). If \((a^i)\) are not all simple, for instance \( a^1 = a^2 \), then equation (4.3) has a double root \( u = a^1 \). ■

The tensors \( K \) and \( L \) have a mechanical meaning: they were introduced in [4] as the inertia tensor and planar inertia tensor of a set of massive points (including, this is important, negative masses) in \( \mathbb{E}_n \). The parameter \( m \) is just the total mass (it may be 0). Indeed, it is a remarkable fact that an inertia tensor is a KT. This interpretation is of help in the problem of finding the intrinsic expressions of all the ChKT’s of \( \mathbb{E}_n \) (see also [41]).

**Notation 4.5.** A matrix of the kind \( A + r \otimes r \) has been used by Moser [44] for constructing a Lax pair for the geodesic flow of an asymmetric ellipsoid. For this reason it was denoted by \( L \) in [4] (indeed, in analogy with the Lax method, starting from \( L \) we can construct a complete system of first integrals in involution through a pure algebraic process). There were other two reasons which suggested this notation: (i) \( L \) is a letter adjacent to \( K \), and this is appropriate because a tensor \( L \) generates a tensor \( K \) according to (4.2); (ii) \( L \) stands for Levi-Civita, and indeed the orthogonal metric associated with \( L \) was firstly introduced by Levi-Civita [36] (see the end of Section 7).

## 5 First integrals associated with the orthogonal separation

Going back to the characteristic equation (4.1) we recall that at the beginning of Section 3 we observed that a characteristic Killing tensor, like that appearing in equation (4.1), generates a KS-space \( \mathcal{K} \). It is a remarkable fact that

**Theorem 5.1.** If \((K_a) = (K_0, K_2, \ldots, K_{n-1})\) is a basis of \( \mathcal{K} \) (\( G \) and \( K \) may belong to this basis) then locally there exist functions \( V_a \) such that

\[
H_a = \frac{1}{2} P_{K_a} + V_a
\]

are independent first integrals in involution.
A proof can be found in [6]. Indeed, it can be shown that equation (4.1) implies \( d(K_a dV) = 0 \) for each index \( a \). This implies that a ChKT \( K \) and a separable potential \( V \) generate a \( n \)-dimensional space \( \mathcal{H}(K, V) \) of first integrals in involution,

\[
H_K = \frac{1}{2}P_K + V_K, \quad K \in \mathcal{K},
\]

and that the associated potentials \( V_K \) can be determined by integrating the closed 1-forms \( K_a dV \). We observe that there are separable systems (an example is the three-body Calogero system, see [11]) in which this integration can be avoided and replaced by an algebraic process.

We remark that, if we know a basis of a KS-space, then for testing if a potential \( V \) is separable it is sufficient to verify that equation (4.1) is satisfied for an element of this space with simple eigenvalues. When the answer is affirmative, then a complete set of integrals in involution can be determined by integrating the closed 1-forms \( K_a dV \).

It is well known that the orthogonal (as well as the non-orthogonal separation) is related to Stäckel matrices. A Stäckel matrix in the \( n \) variables \( (q^i) \) is a regular \( n \times n \) matrix \( S = [\varphi_i^{(a)}] \) of functions \( \varphi_i^{(a)} \) depending on the variable \( q^i \) corresponding to the lower index only. We denote by \( [\varphi_i^{(a)}]^{-1} \) the inverse matrix. The original Stäckel theorem asserts that an orthogonal coordinate system \( (q^i) \) is separable if and only if there exists a Stäckel matrix such that \( g^{ii} = \varphi_i^{(0)} \).

In this case, (i) the diagonalised tensors \( K^{aa}_{ii} = \varphi_i^{(a)} \) are the basis of a Stäckel space, (ii) all separable potentials \( V \) have the form \( V = \phi_i(q^i)\varphi_i^{(0)} \), where \( \phi_i \) is a function of the corresponding coordinate \( q^i \) only; (iii) a basis \( H_a \) of the space of first integrals in involution is given by \( (5.1) \) with \( V_a = \phi_i\varphi_i^{(a)} \).

6 Conformal Killing tensors

As remarked above, the existence of a KT \( K \) with simple eigenvalues and normal eigenvectors is a necessary and sufficient condition for the existence of a KS-space \( \mathcal{K} \), i.e., of a \( n \)-dimensional linear space of KT’s with common normal eigenvectors (and, consequently, in involution). The following question arises: is it possible to construct a basis of the space \( \mathcal{K} \) by a coordinate independent algebraic procedure, starting from \( K \)? Note that this problem can be solved (in principle) by integrating the linear differential system (2.2), if we know a separable coordinate system.

As illustrated in [4] the answer is affirmative at least for special kinds of Stäckel systems. In the next sections we will revisit this matter, by proposing new definitions and theorems. To this end, we need to recall some basic definitions and properties concerning conformal Killing tensors.

A conformal Killing tensor (CKT) on a Riemannian manifold \( Q_n \) is a symmetric tensor \( L \) of order \( l \) satisfying equation \( \{P_L, P_G\} = P_X P_G \), where \( X \) is a suitable symmetric tensor of order \( l - 1 \). Since we are interested in CKT’s of order two, we write this equation in the form

\[
\{P_L, P_G\} = -2P_C P_G, \quad (6.1)
\]

where \( C \) is a vector field which we call associated with \( L \) (also denoted by \( C(L) \)).

\(^2\)Stäckel systems have been the object of several researches in recent years. A generalisation of Stäckel systems has been proposed in [19]. Relations between finite- (Stäckel systems) and infinite-dimensional (Harry–Dym hierarchies) integrable systems are investigated in [40]. The separability of a Hamiltonian in different Stäckel systems is a standard procedure to determine superintegrable systems (see [43] and references therein). More links between Stäckel systems and superintegrability are shown in [54]. An analysis of the Killing–Stäckel spaces is the basis for a classification of the orthogonal separable coordinates in [46]. (Bibliographical footnotes added by Giovanni Rastelli.)
A CKT is said to be of gradient-type (GCKT) if $C = \nabla f$. An example of GCKT is $fG$. In this case we have $C = \nabla f$. Indeed, $\{P_fG, P_G\} = \{fP_fG, P_G\} = P_G\{f, P_G\} = -2g^{ij}p_j\partial_ifP_G$. A KT is obviously a GCKT with $C = 0$.

**Theorem 6.1.** A CKT $L$ is of gradient-type with $C = \nabla f$ if and only if $K = fG - L$ is a Killing tensor.

**Proof.** $\{P_fG, P_G\} = \{P_L, P_G\} - P_G\{f, P_G\} = -2P_CP_G + 2P_G\nabla_f$.

A conformal Killing tensor of trace-type $L$ is a KT for which $C = \nabla \text{tr}(L)$. In this case, $K = \text{tr}(L)G - L$ is a KT.

By considering in (6.1) $P_G = g^{ii}p_i^2$ and $P_L = u^i g^{ii}p_i^2$, we find

**Theorem 6.2.** Assume that a symmetric 2-tensor $L$ is diagonalised in orthogonal coordinates, so that $L^{ii} = u^ig^{ii}$, $L^{ij} = 0$, $i \neq j$, where $u^i$ are the eigenvalues. Then $L$ is a CKT if and only if the following equations are satisfied,

\[ \partial_i u^k = (u^i - u^k)\partial_i \ln g^{kk} + C_i, \quad C_i = \partial_i u^i. \]  

(6.2)

7 L-tensors

Let us call $L$-tensor a (i) conformal Killing tensor $L$ with (ii) vanishing torsion and (iii) pointwise simple eigenvalues ($u^i$). The reasons for introducing such an object will be explained in the next section. In the present section we examine the basic properties of an $L$-tensor. Due to the vanishing of the torsion, there is an equivalence classes of orthogonal coordinates ($q^i$) in which this tensor is diagonalised and $\partial_i u^j = 0$ for $i \neq j$. We say that these coordinates are associated with $L$. Since $L$ is a CKT, due to Theorem 6.2 equations

\[ \partial_i u^j = (u^i - u^j)\partial_i \ln g^{jj} + C_i = 0, \quad i \neq j, \quad C_i = \partial_i u^i \]  

(7.1)

hold. For $C = 0$ we find the equations (2.2) of a KT.

**Remark 7.1.** In the above definition no assumption is made about the independence of the eigenvalues as functions on $Q$; some of them may be constant (a criterion for the independence of the eigenvalues is given in Theorem 9.2 below). This definition has to be compared with those given in [15, 20, 30], where $L$ is assumed to be a torsionless CKT of trace-type (and called Benenti tensor), and in [22, 23], where $L$ is assumed to be a torsionless CKT with independent (i.e., coordinate-forming) eigenvalues (and called special conformal Killing tensor, see Theorem 9.1 below). In all these papers the essential condition that $L$ has simple eigenvalues is missing (or understood).

In fact it can be proved that

**Theorem 7.2.** If an eigenvalue $u^i$ of a torsionless CKT of trace-type is not simple, then it is constant.

The proof of this theorem (here omitted) requires the use of the Haantjes theorem for a tensor with non-simple eigenvalues.

**Theorem 7.3.** Let $L$ be an $L$-tensor with associated coordinates ($q^i$). Then: (i) Each eigenvalue $u^i$ depends on the associated coordinate $q^i$ only, $u^i = u^i(q^i)$. (ii) It is of trace-type, $C = \nabla \text{tr}(L)$. (iii) In associated coordinates the metric has the form

\[ g^{kk} = \phi_k \prod_{i \neq k} \frac{1}{|u^i - u^k|}, \quad u^i = u^i(q^i), \quad \phi_k = \phi_k(q^k) > 0, \]  

(7.2)
or, after a rescaling

\[ g^{kk} = \prod_{i \neq k} \frac{1}{u^i - u^k}. \]  

(7.3)

In both cases,

\[ \partial_i \ln g^{kk} = \frac{\partial_i u^i}{u^k - u^i}, \quad i \neq k. \]

(We call normal coordinates associated with \( L \) the orthogonal coordinates for which equations (7.3) hold). (iv) The associated coordinates are separable. (v) \( L \) commutes with the Ricci tensor \( R, [L, R] = 0 \), i.e., the Robertson condition is satisfied: in the associated coordinates, \( R_{ij} = 0 \) for \( i \neq j \).

These properties are derived from [4, 6]. They follow from equations (7.1) and from the fundamental properties of the elementary symmetric polynomials (see the next section). From (7.2) it follows that the contracted Christoffel symbols \( \Gamma_i = g^{bij} \Gamma_{hji} \) take the simple form \( \Gamma_i = -\frac{1}{2} \delta_i^k \partial_k \phi \).

Thus, in normal coordinates \( \Gamma_i = 0 \). Since in separable orthogonal coordinates \( R_{ij} = \frac{2}{\partial_i \Gamma_j} \), for \( i \neq j \), the Robertson condition (v) is proved. Item (ii) (which follows from (7.1): \( C_i = \partial_i u^i \) and \( \partial_i u^j = 0 \) for \( i \neq j \) implies \( C_i = \partial_i \sum_j u^j \)) shows that in [22, Proposition 1, Section 1] the assumption that \( (u^i) \) are functionally independent eigenvalues is redundant.

It is a remarkable fact that the metric (7.2) associated with \( L \) is that of the corresponding geodesics found by Levi-Civita [36]: there exists a metric \( \mathbf{G} = (g^{ij}) \) having the same (unparametrized) geodesics of a given metric \( \mathbf{G} = (g^{ij}) \) if and only if there are orthogonal coordinates in which the metric \( \mathbf{G} \) assumes the form (7.2). It must be pointed out that this theorem holds under the assumption that the tensor \( \mathbf{G} \) has simple eigenvalues with respect to \( \mathbf{G} \).

This matter has been recently analysed by Bolsinov and Matveev [20] and by Crampin [23]. The metric (7.2) is a special case of the orthogonal separable metric determined by Eisenhart [27, Appendix 13] and characterised by the condition \( R_{ijkl} = 0 \) for \( i, j, k \neq l \).

8 L-systems

Let \( \sigma_a(u) \) denote the elementary symmetric polynomial of degree \( a \) of the \( n \) variables \( u = (u^i) \). Let \( \sigma_a^i \) and \( \sigma_a^{ij} \) be the functions obtained from \( \sigma_a \) by setting \( u^i = 0 \) and \( u^j = 0 \). Let us set

\[ \sigma_0 = \sigma_0^i = \sigma_0^{ij} = 1, \quad \sigma_{-1} = \sigma_{-1}^i = \sigma_{-1}^{ij} = 0, \quad \sigma_n^i = \sigma_n^{ij} = 0. \]  

(8.1)

Then the following equations are satisfied [4, Section 2]:

\[ \sigma_a = \sigma_a^i + u^i \sigma_{a-1}^i, \quad \sigma_a^j = \sigma_a^{ij} + u^j \sigma_{a-1}^{ij}, \quad \sigma_{a-1}^i - \sigma_{a}^i = (u^j - u^i) \sigma_{a-1}^{ij}. \]  

(8.2)

\[ \sum_i u^i \sigma_{a-1}^i = a \sigma_a, \quad \det [\sigma_a^i] = \prod_{j>i} (u^i - u^j). \]  

(8.3)

\[ \frac{\partial \sigma_a^i}{\partial u^i} = \sigma_{a-1}^i, \quad \frac{\partial \sigma_a^j}{\partial u^i} = \sigma_{a-1}^{ij}, \quad (u^j - u^i) \frac{\partial \sigma_a^j}{\partial u^i} = \sigma_a^i - \sigma_a^j. \]  

(8.4)

If \( u^i \neq u^j \) for \( i \neq j \), then

\[ \frac{\partial \sigma_a^j}{\partial u^i} = \frac{\sigma_a^i - \sigma_a^j}{u^j - u^i}, \quad \det [\sigma_a^i] \neq 0, \quad a = 0, 1, \ldots, n-1, \quad i = 1, \ldots, n. \]

It follows that for any coordinate system \( (q^i) \),

\[ \partial_i \sigma_a^j = \partial_i u^h \frac{\partial \sigma_a^j}{\partial u^h} = \sum_{h \neq j} \partial_i u^h \sigma_{a-1}^{hj} = \sum_{h \neq j} \partial_i u^h \frac{\sigma_a^h - \sigma_a^j}{u^h - u^j}. \]  

(8.5)
Theorem 8.1. Let $L$ be a symmetric 2-tensor with eigenvalues $(u^i)$. The tensors $(K_a) = (K_0, K_1, \ldots, K_{n-1})$ defined by

$$K_0 = G, \quad K_a = \frac{1}{a} \text{tr}(K_{a-1}L)G - K_{a-1}L, \quad a > 0,$$

or by

$$K_a = \sum_{k=0}^{a} (-1)^k \sigma_{a-k} L^k, \quad K_a = \sigma_a G - K_{a-1}L, \quad K_{-1} = 0,$$

form a basis of a KS-space if and only if $L$ is an L-tensor.

Proof. (i) Assume that $(K_a)$ defined by (8.6) is a basis of a KS-space. Then they are linearly independent and there are orthogonal (separable) coordinates in which these tensors as well as $L$ are diagonalised and equations

$$\partial_i \rho^i_a = (\rho^i_a - \rho^i_{a-1}) \partial_i \ln g^{jj}, \quad \det [\rho^i_a] \neq 0,$$

hold, being $\rho^i_a$ the eigenvalues of $K_a$. Due to (8.6), these eigenvalues fulfill the recurrence relation $\rho^i_a = \frac{1}{a} \sum_k \rho^i_{a-k} u^k - \rho^i_{a-1} u^1$. On the other hand, from the first equations (8.3) and (8.2) we get $\frac{1}{a} \sum_k \sigma_{a-k} u^k - \sigma_{a-1} u^1 = \sigma_a - \sigma_{a-1} u^1 = \sigma_a$. This shows that

$$\rho^i_a = \sigma_a(u).$$

It follows that: (I) Due to the second equations (8.3) and (8.8), the eigenvalues $u^i$ are simple. (II) Due to the first equation (8.2), the definition (8.6) implies the alternative definitions (8.7). (III) Due to the first equation (8.8), $\partial_i \rho^i_a = 0$ thus, $0 = \sum_{h \neq i} \partial_i u^h \sigma_{a-1}^{h1}$. Let us consider the case $i = 1$. We get the linear homogeneous system of $n - 1$ equations

$$\sum_{h>1} \partial_1 u^h \sigma_{a-1}^{h1} = 0, \quad a = 1, \ldots, n - 1,$$

in the $n - 1$ unknown functions $\partial_1 u^h$, with $h = 2, \ldots, n$. We can put $\sigma_{a-1}^{h1} = \bar{\sigma}_{b}^{h}$, where $\bar{\sigma}_{b}^{h}, b = 0, \ldots, n - 2$, are the symmetric polynomials in the $n - 1$ variables $(u^2, \ldots, u^n)$. In analogy with the third equation (8.4) we have $\det [\bar{\sigma}_{b}^{h}] = \prod_{j>i} (u^j - u^i)$, thus $\det [\bar{\sigma}_{b}^{h}] = \det [\sigma_{a-1}^{h1}] \neq 0$. It follows from (8.9) that $\partial_1 u^h = 0$ for all $h > 1$. In a similar way we prove that $\partial_1 u^h = 0$ for all $h \neq i$. This shows that $H(L) = 0$. Finally, from $K_1 = \text{tr}(K_1L) - L$ we get

$$L \doteq \frac{1}{n-1} \text{tr}(K_1)G - K_1.$$

Being $K_1$ a KT, $L$ is a CKT. (ii) Conversely, assume that $L$ is an L-tensor. In coordinates associated with $L$ we have $\partial_i u^h = 0$ for all $h \neq i$, and moreover, $0 = (u^i - u^j) \partial_i \ln g^{jj} + \partial_i u^i$. By (8.5) we get

$$\partial_i \sigma^i_a = \partial_i u^i \frac{\sigma^i_a - \sigma^j_a}{u^j - u^i} = (\sigma^i_a - \sigma^j_a) \partial_i \ln g^{jj}.$$

Being $\rho^i_a = \sigma^i_a$, this shows that the tensors $K_a$ are Killing tensors. They are pointwise independent due to (8.3). \hfill \blacksquare

We call $L$-system any separable orthogonal system whose KS-space is generated by an L-tensor according to Theorem 8.1. We call $L$-web any orthogonal web corresponding to an L-system.\footnote{L-systems have been considered in \cite{17, 18}. See also the extensive classification \cite{9} of special symmetric two-tensors (including L-tensors) with application to the theory of the equivalent dynamical systems and to the theory of cofactor and bi-cofactor systems.}
Remarks 8.2.

(i) All the Killing tensors $K_a$ ($a \neq 0$) have simple eigenvalues. The sequence (8.6) was suggested by the analysis [4] of the planar inertia tensor $L$ of an asymmetric massive body in the Euclidean $n$-space. The tensor $K_1$ is the corresponding inertia tensor. Formula (8.7) shows that $K_a = 0$ for $a > n - 1$, since for $a = n$ the right-hand side vanishes due to the Hamilton–Cayley theorem. Formula (8.6) is more effective than (8.7) since it does not require the knowledge of the eigenvalues of $L$.

(ii) Within a completely different context, a sequence like (8.6) is considered by Schouten [49, p. 30] generated by a matrix $P$, as an effective tool for computing the eigenvectors of a matrix $P$ without solving systems of linear equations (when the eigenvalues are known and simple). Such a method was firstly introduced by Fettis [28] and Souriau [51].

(iii) We observe with Schouten [49] that the (1,1) tensor $Q(x) = \text{cof}(L - xG)$ is polynomial of degree $n - 1$ in $x$, whose coefficients, up to the sign, are the tensors $K_a$ defined in (8.7). We recall that the cofactor $\hat{A} = \text{cof}(A)$ of $A$ is defined by $AA = A\hat{A} = \det(A)G$. Hence, the Stäckel systems of the kind considered in the last two theorems are just the so-called cofactor systems (cf. [16]). In fact, they should be called Levi-Civita systems (so that “L-systems” is a good notation) since the separable metric (7.3) (but not the tensor $L$) appears for the first time in [36], where it is also shown that for such a metric the function

$$F(q, \dot{q}, c) = \prod_{j \neq i} (u^j + c)|u^j - u^i| (\dot{q}^i)^2$$

is a first integral of the geodesics for all values of the parameter $c$. Since $F$ is a polynomial in $c$ of degree $n - 1$, its coefficients give rise to $n$ first integrals. These first integrals coincide, up to the sign and after the Legendre transformation, with the first integrals $P(K_a)$.

(iv) Due to item (v) of Theorem 7.3, a necessary condition for a Stäckel system to be an L-system is the Robertson condition: $[K, R] = 0$ for a characteristic tensor $K$ (thus, for all elements of the KS-space).

A criterion for testing if a Stäckel system is an L-system is the following.

**Theorem 8.3.** A Stäckel system is an L-system if and only if in the corresponding KS-space there exists a characteristic tensor $K_1$ such that the tensor $L$ defined by (8.10) is torsionless.

**Proof.** (i) Assume that there exists a ChKT $K_1$ such that the tensor $L$ defined by (8.10) is torsionless. Any tensor of the kind $fG + K$ is a CKT if $K$ is a KT. Since $K_1$ has simple eigenvalues, also $L$ has simple eigenvalues. Then $L$ is an L-tensor. The tensors $K_a$ constructed by applying (8.6) form a KS-space $\mathcal{K}_a$ which has $K_1$ in common with the original KS-space $\mathcal{K}$. Thus, $\mathcal{K}_a = \mathcal{K}$ since two KS-spaces with a ChKT in common coincide. (ii) The converse is obvious. $\blacksquare$

About the uniqueness of an L-tensor generating an L-system, it can be proved that

**Theorem 8.4.** Two L-tensors $L$ and $\tilde{L}$ generates the same L-system if and only if $\tilde{L} = aL + bG$, $a, b \in \mathbb{R}$, $a \neq 0$.

In accordance with the remarks at the end of Section 5, a basis $(K_a)$ of a KS-space corresponds to the inverse of a Stäckel matrix $S^{-1} = [\varphi_i^j(a)]$, $\varphi_i^j(a) = K_a^{ii}$. In the sequence (8.6) we have $K_0 = G$, then $\varphi_i^j(0) = g^{ii}$ and $\varphi_i^j(a) = K_a^{ii} = \sigma_i^a g^{ii}$. By using the formulas concerning the elementary symmetric function at the beginning of Section 8 it can be proved that
\textbf{Theorem 8.5.} For an L-system the St"ackel matrix associated with the basis (8.6), $S = [\varphi_{i}^{(a)}]$, assuming $u^1 < u^2 < \cdots < u^n$, is of alternating Vandermonde type,

$$\varphi_{i}^{(a)} = (-1)^{n-a+i}(u^i)^{n-a-1}, \quad a = 0, \ldots, n-1, \quad i = 1, \ldots, n \quad \text{index of row}. \quad (8.11)$$

For $n = 3$ we have (a index of row)

$$[\varphi_{i}^{(a)}] = \begin{bmatrix}
g_{11} & g_{22} & g_{33} \\
(u^2 + u^3)g_{11} & (u^3 + u^1)g_{22} & (u^1 + u^2)g_{33} \\
u^2u^3g_{11} & u^3u^1g_{22} & u^1u^2g_{33}
g_{11} = \frac{1}{(u^1 - u^2)(u^1 - u^3)}, \quad g_{22} = \frac{1}{(u^2 - u^3)(u^2 - u^1)}, \quad g_{33} = \frac{1}{(u^3 - u^2)(u^3 - u^1)}.
\end{bmatrix}$$

In accordance with Theorem 8.1, the inverse matrix is

$$S = [\varphi_{i}^{(a)}]^{-1} = \begin{bmatrix}
(u^1)^2 & -u^1 & 1 \\
-(u^2)^2 & u^2 & -1 \\
(u^3)^2 & -u^3 & 1
\end{bmatrix}.$$

\textbf{Remark 8.6.} If we multiply each row $\varphi_{i}^{(a)}$ of a St"ackel matrix by a function $f_i(q^i) \neq 0$, then we get a new St"ackel matrix $\varphi_{i}^{(a)} = f_i\varphi_{i}^{(a)}$ whose inverse $\tilde{\varphi}_{i}^{(a)}$ defines a new basis of the same KS-space. By multiplying the lines of (8.11) by $\pm 1$ in a suitable way and by changing $L$ in $-L$, we can get a St"ackel matrix which is of the Vandermonde type (see the case $n = 3$, for instance).

9 The functional independence of the eigenvalues of an L-tensor

The results of Section 8 hold without any assumption on the functional independence of the eigenvalues $(u^i)$ of $L$. Some of them may be constant. The only essential assumption is that they are pairwise and pointwise distinct. The following theorems deal with this matter.

\textbf{Theorem 9.1.} If a torsionless CKT has functionally independent eigenvalues $(u^i)$, then it is an L-tensor (its eigenvalues are pointwise simple).

\textbf{Proof.} In this case the eigenvalues define local orthogonal coordinates $q^i = u^i$ in which the tensor is diagonalised. We can apply Theorem 6.2. Equations (6.2) become $\delta_{i}^{k} = (u^i - u^k)\partial_i \ln g^{kk} + 1$. For $i \neq k$ we have $u^i \neq u^k$. \hfill $\blacksquare$

Note that in this case $L$ is a special type of L-tensor (the type considered by Crampin [22, 23]).

\textbf{Theorem 9.2.} Let $L$ be an L-tensor. (i) The eigenvalues $(u^i)$ of $L$ are independent functions (i.e., they define locally an orthogonal coordinate system) if and only if $L$ is not invariant with respect to a Killing vector $X$. (ii) If there exists a Killing vector $X$ such that $[X, L] = 0$, then $X$ is a linear combination (with constant coefficients) of Killing vectors in involution which are eigenvectors of $L$.

In case (i) we have no symmetry of the separable web generated by the eigenvectors of $L$. This means that all the structures associated with $L$ are not invariant with respect to groups of isometries.
Theorem 9.3. Let \( L \) be an L-tensor. (i) If \( L \) has all constant eigenvalues, then the manifold \( Q \) is locally flat and \( L = \text{const} \) (in the sense that all its components in Cartesian coordinates are constant). (ii) If \( L \) is invariant with respect to \( m < n \) Killing vectors, then these vectors are not translations.
10 L-potentials

In this section we propose a few remarks on the potential functions associated with an L-system. For further approaches to this matter we refer the reader to [16, 30]. By virtue of (1.3) and (7.3) we have

**Theorem 10.1.** A potential $V$ is separable in an L-system if and only if, with respect to normal coordinates $(q^i)$ associated with $L$,

$$\partial_i \partial_j V = \frac{1}{w^i - u^i} (\partial_j V - \partial_i V), \quad \partial_i = \partial / \partial q^i.$$

Note that in this theorem (as well as in the following) the eigenvalues $u^i$ of $L$ may not be independent functions.

**Theorem 10.2.** Let $(K_a)$ be the basis of the KS-space generated by an L-tensor $L$ according to formula (8.6). Then the functions $V_a(u) = \sigma^a_{a+1}(u)$ $(a = 0, 1, \ldots, n - 1)$ fulfill equations $dV_a = K_a dV$, with $V = V_0 = \text{tr}(L) = \sum_i u^i$, and the functions $H_a = \frac{1}{2} P_{K_a} + V_a$ are first integrals in involution.

**Proof.** $K_a dV = \sigma^a_{a+1} \partial_i V dq^i = \sigma^a_{a+1} dq^i = \partial_i \sigma^i_{a+1} dq^i = dV_a$. Apply (5.1).

11 L-pencils

There are Stäckel webs which are not L-webs. A necessary condition is the Robertson condition. However, also in manifolds where this condition is identically satisfied, for instance in constant curvature spaces, there are Stäckel systems which are not generated by an L-tensor. For instance, due to Theorem 9.3(ii), in a $E_n$ all translational webs (except the Cartesian web) are not L-webs. As remarked above, also the spherical-conical webs are not L-webs. This last case has suggested [4] the introduction of a linear combination

$$L(m) = L_0 + mL_1,$$

which is an L-tensor for all values the parameter $m \in \mathbb{R}$. We call L-pencil such an object.

**Theorem 11.1.** Let $L = L_0 + mL_1$ be an L-pencil. Then:

(i) $L_0$ has simple eigenvalues.

(ii) $L$ is a CKT for all $m$ if and only if $L_0$ and $L_1$ are CKT’s.

(iii) The condition $H(L) = 0$ is equivalent to

$$H(L_0) = H(L_1) = 0, \quad L^h_i \partial_0^i L^k_j = L^h_i \partial_0^i L^k_j + L^h_i \partial_0^i L^k_j - L^h_i \partial_0^i L^k_j = 0.$$

(iv) The Ricci tensor $R$ commutes with both $L_0$ and $L_1$.

The proof is straightforward. Let us apply the iterative formula (8.6) and Theorem 8.1 to the tensor $L(m)$. Since $L$ is polynomial of degree 1 in $m$, each tensor $K_a(m)$ is at most of degree $a$: $K_a(m) = H_a m^a + H_{a-1} m^{a-1} + \cdots$.

**Theorem 11.2.** (i) The tensors $K_a(0)$ form a KS-space. (ii) The tensors $H_a$, given by the coefficients of maximal degree of $K_a(m)$, if independent, form a KS-space. (iii) The Stäckel systems generated by these two KS-spaces satisfy the Robertson condition.

---

4See also [10].
Also for this statement we omit the proof. We remark that there are cases in which all the $K_a$ are of degree 1, as in the following example.

**Example 11.3** ([4]). In $\mathbb{E}_n$ we consider the tensor $L(m) = L_0 + m r \otimes r$. It represents (for $m \neq 0$) the planar moment of inertia of a massive body with total mass $m$ and center of mass at the origin. $L_0$ is a constant symmetric tensor (hence, a KT) with simple eigenvalues $(a^i)$. $L_1 = r \otimes r$ is a CKT whose eigenvalues are all zero except one ($= r^2$). It can be proved that: (i) $L$ is an L-pencil; (ii) the tensors $K_a(0)$ form a KS-space corresponding to Cartesian coordinates; (iii) $K_a(m)$ are all of degree 1 in $m$, $K_a(m) = K_a(0) + m H_a$; (iv) the tensors $H_a$ form a KS-space corresponding to the conical spherical coordinates.

The above results stimulate investigations about the notion of an L-pencil, also in relation with recent studies on the same concept and the notion of cofactor pair system (see, e.g., [38, 39, 47, 48]). A possible generalisation is a multi-pencil of the type $L = L_0 + m^i L_i$ with $(m^i) \in \mathbb{R}^k$ or $L = m^i L_i$ with $(m^i) \neq 0$. Basic examples are, in the Euclidean $n$-space, the case $L = L_0 + m r \otimes r + wc \otimes r$ where $c$ is a constant unit vector, see (4.2). For brevity, we do not examine here which Stäckel webs in $\mathbb{E}_n$ (or in $S_n$, $\mathbb{H}_n$) are generated by an L-tensor or by an L-pencil.

## 12 The Riemannian background of the separation

Also for a better understanding of the orthogonal separation, it is necessary to study the Levi-Civita equations without any a priori assumptions on the separable coordinates $q$. The geometrical meaning of these equations has been firstly investigated by Kalnins and Miller [32, 33] and in [2] (see also [3, 7]). A result of these investigations is the following.

**Theorem 12.1** ([8]). The Hamilton-Jacobi equation $G + V = E$ is separable if and only if there exists a characteristic Killing pair $(D, K)$ such that

$$DV = 0, \quad d(K dV) = 0. \quad (12.1)$$

A characteristic Killing pair $(D, K)$ is made of a $r$-dimensional linear space $D$ of commuting Killing vectors and a $D$-invariant Killing tensor $K$ having $m = n - r$ normal eigenvectors orthogonal to $D$ and corresponding to distinct eigenvalues (note that these eigenvalues may not be simple). Since the elements of $D$ are in involution, they generate $r$-dimensional orbits which are locally flat submanifolds. It can be shown that if $(D, K)$ is a characteristic Killing pair, then $D$ is normal, in the sense that the distribution orthogonal to its elements is completely integrable. This means that there is a foliation of $m$-dimensional manifolds orthogonal to the orbits of $D$. The leaves of this foliation are isometric Riemannian manifolds (the isometries being generated by the orbits of $D$, assuming that they intersect the orbits in only one point).

With a characteristic Killing pair we associate standard separable coordinates $(q^a) = (q^a, q^a)$ ($a = 1, \ldots, m$, $\alpha = m + 1, \ldots, n$) defined in this way: (i) $dq^a$ are eigenforms of $K$ orthogonal to $D$ (or, equivalently, the orbits of $D$ are defined by equations $q^a = \text{const}$); (ii) the $(q^a)$ are the affine parameters, with zero value on an arbitrary $m$-dimensional orthogonal section $\mathcal{Z}$ of the orbits of $D$, of Killing vectors $X_\alpha$ forming a local basis of $D$. It follows that: (I) $\partial / \partial q^a = X_\alpha$ and the coordinates $(q^a)$ are ignorable; (II) in these coordinates the contravariant metric tensor components assume the standard form

$$[g^{ij}] = \begin{bmatrix} [g^{aa}] & [0] \\ [0] & [g^{ab}] \end{bmatrix}, \quad (12.2)$$
where \([g^{\alpha \alpha}]\) is a diagonal \(m \times m\) matrix and \([g^{\alpha \beta}]\) is a \(r \times r\) matrix, with \(m = n - r\). Here we denote by \([0]\) zero-matrices of proper dimensions. The rather long proof of this theorem is based on the following

**Theorem 12.2** ([2]). *In an equivalence class of separable coordinates there exist coordinates in which the metric assume the standard form (12.2).*

Two separable systems are called *equivalent* if (in the intersection of their domains of definition) the corresponding separated solutions of the Hamilton–Jacobi equation generate the same Lagrangian foliation of \(T^*Q\). The geometrical representation of an equivalent class is given by a *separable web*: it is a pair \((D, S^a) = (D, (S^1, \ldots, S^m))\), where \(D\) is a normal \(r\)-dimensional space of commuting KT’s and \((S^a)\) is a family of \(m\) orthogonal foliations of submanifolds of codimension 1, all invariant with respect to \(D\) (it follows that the orbits of \(D\) are the complete intersections of the \((S^a)\)). Moreover, the submanifolds \((S^a)\) are orthogonal to \(m\) eigenvectors of a \(D\)-invariant KT \(K\) with distinct (but not necessarily simple) eigenvalues (so that \((D, K)\) is a characteristic Killing pair). It must be observed that the quotient set of the orbits of \(D\) is a \(m\)-dimensional manifold with a naturally induced orthogonal separable metric \((g^{\alpha \alpha})\) (it is isomorphic to any \(m\)-manifold orthogonal to \(D\)).

In this description of the separation we include the extreme cases: (I) \(m = n, r = 0\), which corresponds to the an orthogonal separation; (II) \(m = 0, r = n\), which corresponds to the separation in Cartesian coordinates (in this case the manifold is flat). In [13] it is proved that

**Theorem 12.3.** *A characteristic Killing pair \((D, K)\) generates a \(m\)-dimensional space \(K_m\) of Killing tensors with the following properties: (i) they are \(D\)-invariant and have \(m\) eigenvectors in common orthogonal to \(D\); (ii) they are in involution; (iii) if the characteristic equations (12.1) of a separable potential \(V\) are satisfied, then they are satisfied by all elements of \(K_m\).*

**Theorem 12.4.** *In a space \(K_m\) having properties (i) and (ii), where \(D\) is a \(n - m\)-space of Killing vectors in involution, all the common eigenvectors are normal.*

**Theorem 12.5.** *The functions \(H_\alpha = \frac{1}{2} P_{K_\alpha} + V_\alpha\) and \(P_{X_\alpha} = X_\alpha p_i\), where \(dV_\alpha = K_\alpha dV\) and \((X_\alpha)\) is a basis of \(D\), form a complete system of integrals in involution.*

Theorems 12.2 and 12.3 show that if \(D\) admits an orthogonal basis, \(X_\alpha \cdot X_\beta = 0\) for \(\alpha \neq \beta\), then the standard coordinates are orthogonal. This means that the separation occurs in orthogonal coordinates. It can be proved by a coordinate-independent method that

**Theorem 12.6** ([5]). *On a manifold with constant curvature any normal space \(D\) of Killing vectors in involution has an orthogonal basis.*

As a consequence,

**Theorem 12.7.** *On a manifold of constant curvature the geodesic separation always occurs in orthogonal coordinates.*

This important property was discovered by Kalnins and Miller [34, 35] (see also [31]), within a coordinate-dependent approach. This theorem can be extended to a natural Hamiltonian \(H = G + V\).\(^5\)

\(^5\)The study of the Riemannian background of the separation has been extended to a Hamiltonian with scalar and vector potential in [12].
