BCL6 suppresses an IL10RA/JAK2/STAT3 pathway

Synthetic lethal screen demonstrates that a JAK2 inhibitor suppresses a BCL6 dependent IL10RA/JAK2/STAT3 pathway in high grade B-cell lymphoma.

ABSTRACT
We demonstrate the usefulness of synthetic lethal screening of a conditionally BCL6 deficient Burkitt lymphoma cell line, DG75-AB7, with a library of small molecules to determine survival pathways suppressed by BCL6 and suggest mechanism-based treatments for lymphoma. Lestaurtinib, a JAK2 inhibitor and one of the hits from the screen repressed survival of BCL6 deficient cells in vitro and reduced growth and proliferation of xenografts in vivo. BCL6 deficiency in DG75-AB7 induced JAK2 mRNA and protein expression and STAT3 phosphorylation. Surface IL10RA was elevated by BCL6 deficiency and blockade of IL10RA repressed STAT3 phosphorylation. Therefore, we define an IL10RA/JAK2/STAT3 pathway each component of which is repressed by BCL6. We also show, for the first time, that JAK2 is a direct BCL6 target gene: BCL6 bound to the JAK2 promoter in vitro and was enriched by ChIP-seq. The place of JAK2 inhibitors in the treatment of diffuse large B-cell lymphoma has not been defined: we suggest that JAK2 inhibitors might be most effective in poor prognosis ABC-DLBCL, which shows higher levels of IL10RA, JAK2 and STAT3 but lower levels of BCL6 than GC-DLBCL and might be usefully combined with novel approaches such as inhibition of IL10RA.

INTRODUCTION
There is a need for new treatments for poor-prognosis activated B-cell like diffuse large B-cell lymphoma (ABC-DLBCL), which continues to have a cure rate lower than 40% with conventional chemotherapy(1).

The majority of ABC-DLBCL, in contrast to germinal centre B-cell like (GCB)-DLBCL, have low-level expression of BCL6 mRNA and protein(2). JAK/STAT3 signalling is active in ABC-DLBCL and is enhanced by constitutive activity of the NF-κB pathway(3), which in turn is driven by oncogenic CARD11 mutations(4), chronic active B-cell receptor signalling(5) and MYD88 mutations(6). However, other factors are also likely to be important in determining the overall activity of JAK/STAT3 signalling. BCL6 directly represses both STAT3(7) and NF-κB p105/p50(8) transcription and levels of BCL6 might, therefore, be a factor, independent of the
known oncogenic mutations, which determines the activity of signalling pathways required by ABC-DLBCL. In this report we develop a novel B-cell line in order to pursue the hypothesis that genes repressed by BCL6 are components of survival signalling pathways in lymphomas with low-level expression of this transcription factor.

BCL6 is a zinc finger transcription factor, which is highly expressed in normal germinal centre B-cells(9), and is required for high affinity antibody production(10, 11). It is also constitutively expressed in ~40% of cases of the high grade B-cell lymphoma DLBCL, due to either chromosomal translocations, mutations of a negative regulatory site in the promoter region(12-14) or abnormalities of post-translational regulation(15-17).

The N-terminal POZ domain of BCL6 associates with co-repressors NCOR1, BCOR and SMRT (NCOR2), which, in turn recruit histone deacetylases to accomplish transcriptional repression. Work largely carried out with human Burkitt lymphoma cell lines and mouse B-cell lines, showed that BCL6 represses B-cell terminal differentiation through a direct effect on BLIMP1 (PRDM1)(18-20). Effects on the cell cycle have been less clearly defined: BCL6 represses cyclin D2 transcription(18) but it also suppresses the cyclin dependent kinase inhibitor p21(21) and, in primary cells, prevents senescence and induces cyclin D1(22).

Suppression of DNA damage responses and p53 by BCL6 are believed to be required to allow somatic hypermutation in normal germinal centre B-cells (23, 24). As mentioned above, STAT3 and NF-κB, which are both required by ABC-DLBCL, are direct targets of BCL6 transcriptional repression(7, 8).

For this study we defined synthetic lethality as reduction of survival of BCL6 deficient DG75-AB7 cells, whilst relatively sparing BCL6-replete cells. In order to carry out the synthetic lethal screen we employed a library of small molecule inhibitors, which are either in clinical use or good candidates for clinical use. Hits from the screen could, therefore, potentially be rapidly introduced into clinical trials.

We demonstrate that IL10RA and JAK2 are transcriptionally regulated by BCL6 and suggest (7, 29) that low BCL6 is a determinant of an IL10RA/JAK2/STAT3 pathway that might be important in survival of some ABC-DLBCL.

RESULTS
Characterisation of a conditional BCL6 deficient B-cell line: BCL6 deficiency reduces survival and causes accumulation in G1.

We produced conditional BCL6 deficient Burkitt lymphoma cell lines. On addition of doxycycline BCL6 was effectively repressed and proliferation was reduced in three separate clones (Figure 1C and 1D). Further work was carried out with clone DG75-AB7. When doxycycline was washed out of the culture medium the effects on growth were reversed suggesting a continuing requirement for BCL6 (Figure 1E). After 7 days of culture doxycycline treated DG75-AB7 cells had undergone fewer cell divisions than untreated cells (Figure 2A) with accompanying reduction in survival and an increase in cells in G1 at the expense of G2M and S phases (Figure 2B). Overall BCL6 deficient cells showed reduced proliferation due to G1 growth arrest.

Gene expression profiling was carried out in order to obtain a comprehensive view of BCL6 gene target alterations in DG75-AB7. Two hundred and five genes with a ≥ 2-fold up- or down-regulation in at least one of the samples cultured with doxycycline (16 hours, 48 hours or 96 hours) compared to the basal (-doxycycline) sample were identified. 14/205 genes were not annotated and hence excluded from subsequent analysis, leaving 191 genes. Of these 162 genes (85 %) were up-regulated in response to BCL6-depletion (Table 2). Validation by RT-PCR was carried out for a subset of these genes (Figure 3 and Table 3).

In order to identify biological pathways altered in response to BCL6-depletion, functional annotation clustering was carried out (32, 33). Cell cycle gene
CDKN1B (p27kip2) a previously identified BCL6 target gene 18 was up-regulated together with other regulators of cell cycle progression (CDC25A, CDC6, E2F8 and RB1). Other pathways regulated by BCL6 were B-cell receptor signalling (SYK, BLNK, PTPRC (CD45), IFITM1 (LEU13 or CD225), CD72 and PTPN6 (SHP1)) and calcium signalling (CYSLTR1 (GPCR), ATP2A (SERCA1), ITPR1/ITPR2 (IP3R), CAMK4 and PTK2B (FAK2, Pyk2)).

Work by others has demonstrated specific functionally important BCL6 targets(18). Analysis of changes in DG75-AB7 to the mRNA expression of these genes showed ≥30% induction of expression in 14/19 (73%) on addition of doxycycline (Table 4A). In an alternative method to validate the gene expression changes observed in DG75-AB7 we utilised published data, which, in another Burkitt lymphoma cell line, has demonstrated a set of genes that bind BCL6 at their genomic loci(34). 39 of the 44 genes that bound BCL6 by ChIP-qPCR are represented on the gene expression microarrays we employed and 18 (46%) of these showed altered mRNA expression (≥30% induction or repression) at one or more time points following addition of doxycycline to DG75-AB7 (Table 4B). Whilst not all genes discovered through ChIP-chip will be functionally important our data supports a functional role for several e.g. TNFAIP8, TAP1, SUB1 and CD53, that have not yet been investigated in detail.

One of the important effects of BCL6 is suppression of DNA damage responses partly through transcriptional repression of ATR(23). To show that DG75-AB7 reproduces this aspect of BCL6 deficiency DNA damage responses in response to X-irradiation were determined. Culture in doxycycline caused induction of ATR protein in AB7 and significant (Mann-Whitney U-test) reductions in DNA damage in response to X-irradiation (as determined by H2AX phosphorylation) at 1 Gy (P=0.003) 2 Gy (P=0.007) and 4 Gy (P=0.01) (Figure 2C).

Therefore, DG75-AB7 is a model system demonstrating gene expression and functional changes, on addition of doxycycline, in line with known BCL6 effects.

The JAK2 inhibitor, lestaurtinib, reveals a survival pathway in BCL6 deficient cells

We utilised a drug sensitivity screen to determine survival pathways in BCL6 deficient DG75-AB7. The effect of each compound in the library on cell viability was estimated, both in the presence and absence of doxycycline. In each case, the effect was quantified as a z-score, with negative z-scores representing inhibition of cell survival (Figure 4A). As expected the majority of compounds do not show an effect on cell survival but comparison of z-score data from DG75-AB7 cell screens in the presence of doxycycline (BCL6 deficient) or absence of doxycycline (BCL6 replete), allowed identification of compounds that preferentially reduced survival of BCL6 deficient cells whilst having relatively little effect on BCL6 replete cells (Table 1). Seven compounds demonstrated z-scores ≤-2 at two or more concentrations. Of these compounds, paclitaxel and vinorelbine reduced survival of both BCL6 replete and deficient cells whereas others, 2-methoxyestradiol, dasatinib, canertinib, lestaurntinib and sunitinib appeared to preferentially suppress growth of BCL6 deficient cells (Figure 4B). By comparison doxorubicin and flavopiridol (Figure 4C) reduced survival without a differential effect on BCL6 deficient cells whilst cyclophosphamide and olaparib showed no effect on either BCL6 replete or deficient cells.

BCL6 deficiency induces a transcriptional increase in JAK2 levels

We focused further work on the JAK2 inhibitor, lestaurtinib, because BCL6 directly represses STAT3(7), which is a principle target of phosphorylation by JAK2 and we wondered whether BCL6 also repressed JAK2 to cause increased overall inhibition of JAK2 and STAT3.

Addition of doxycycline caused a 4-fold increase in JAK2 mRNA and induction of JAK2 protein (Figure 5A and 5B). Induction of phospho-tyrosine705-STAT3 accompanied these changes and lestaurtinib and two other JAK2 inhibitors, fedratinib and ruxolitinib, prevented phosphorylation (Figure 5C). At the doses employed ruxolitinib and to a lesser extent fedratinib stabilised JAK2 phosphorylation (in line with their mechanism of action as type I inhibitors (35) whilst all three agents repressed STAT3 phosphorylation. STAT3 transcription factor activity is largely associated with phosphorylation on tyrosine705. Westerns, utilising tyrosine705 and serine727 specific anti-phospho-STAT3 showed STAT3 tyrosine705 following induction
of BCL6 deficiency, whilst levels of phosphorylated STAT3 serine727 remain unchanged (Figure 5D). Overall the data demonstrated preferential reduction of survival of BCL6 deficient DG75-AB7 by lestaurtinib and, consistent with this effect being mediated by STAT3, JAK2 inhibitors repressed the STAT3 phosphorylation induced by BCL6 deficiency. In order to confirm reduction in viability observed with lestaurtinib was mediated through JAK2 we transfected DG75-AB7 either with siRNA directed against JAK2 or a negative control siRNA (Figure 5E and 5F). Repression of JAK2 caused a significant (t-test; P=0.008) reduction in cell viability in the presence of doxycycline.

BCL6 deficiency induces IL10RA expression

Serum IL-10 levels are prognostic in DLBCL(36) and IL10 receptor expression was increased in ABC-DLBCL as compared to GC-DLBCL(29). IL10 receptor activation promoted STAT3 phosphorylation and DLBCL survival(29). We wondered whether JAK2/STAT3 phosphorylation required IL10 receptor expression and engagement in DG75-AB7. Induction of BCL6 deficiency induced IL10RA mRNA expression (Figure 5G) and flow cytometry showed elevated surface expression of IL10RA in a population of DG75-AB7 cells (Figure 5H). It is not clear why IL10RA expression was not induced in all cells. Exogenous IL10 induced STAT3 tyrosine phosphorylation, which is repressed by a blocking anti-IL10 antibody (Figure 5I) demonstrating that IL10RA engagement is required for STAT3 phosphorylation. Collectively our data implicates BCL6 in suppressing an IL10RA/JAK2/STAT3 pathway.

Lestaurtinib combined with induced BCL6 deficiency is effective in a mouse xenograft model

To evaluate in vivo efficacy of lestaurtinib in combination with BCL6 deficiency we utilised SCID-beige mouse xenografts. Animals were flank injected with DG75-AB7 and divided into four groups (n=8). Whilst there were no obvious histological differences between tumours in untreated animals and those who had received either doxycycline in the drinking water or lestaurtinib, by intraperitoneal injection, (Figure 6) those tumours from animals that received both agents unexpectedly showed massive central necrosis. As compared to untreated animals, mice that received either doxycycline or lestaurtinib alone showed reduced growth and the combination of agents produced further repression (Figure 6C). Immunohistochemical assessment of proliferation demonstrated that the combination of doxycycline and lestaurtinib increased the fraction of non-proliferating Ki-67 negative cells (Figure 6D). Therefore, BCL6 deficiency was sufficient to markedly repress tumour growth without altering the fraction of Ki-67 expressing cells but the combination of BCL6 deficiency and lestaurtinib significantly (Mann-Whitney U-test; P=0.007) increased numbers of Ki-67 negative cells and was associated with tumour necrosis.

JAK2 is a direct target of BCL6 transcriptional repression

Inspection of the JAK2 promoter region identified a possible BCL6 binding site at -1185 bp from the transcription start site (Figure 7A). In order to demonstrate BCL6 binding to this sequence in vitro we utilised gel shift assays employing lysates from the BCL6 expressing Ramos Burkitt lymphoma cell line and labelled JAK2 promoter BCL6 binding sequence (J2B6BS) oligonucleotide. A protein/DNA complex was effectively competed by a consensus BCL6 binding sequence (FB20) (7) and an anti-BCL6 antibody caused disappearance of the shifted band (Figure 7B), therefore identifying the complex as containing BCL6. FB20 oligonucleotide was able to compete more effectively than J2B6BS for binding to BCL6 suggesting a relatively weak interaction at the JAK2 promoter. To show in vivo BCL6 binding at the JAK2 promoter we analysed publicly available ChIP-seq databases (37). Statistically significant peaks (Table 5) of BCL6 binding corresponded with BCOR co-repressor binding without evidence of SMRT or NCOR binding (Figures 7C and 7D) supporting both a direct effect of BCL6 and association with BCOR at the JAK2 locus. In order to demonstrate BCL6 binding at the JAK2 locus in DG75-AB7 a single site ChIP assay was employed and showed ~30-fold more binding in the absence of doxycycline (Figure 7E). Next reporter assays were carried out in HEK293 cells to demonstrate the functional importance of the binding site, (Figure 7F) demonstrated transcriptional repression in response to transfected BCL6 from the wild-type promoter, and relief of repression following mutation of the BCL6 binding site. This result was confirmed in DG75-AB7 (Figure 7G) Therefore,
there is a functional BCL6 binding site in the JAK2 proximal promoter region and BCL6 binds to this region in vivo supporting the direct transcriptional repression of JAK2 by BCL6. Expression of JAK2 and BCL6 mRNA are inversely correlated in human DLBCL.

In order to obtain data on relative JAK2 and BCL6 mRNA expression in primary human lymphoma we analysed a publicly available gene expression database (38). JAK2 mRNA is expressed significantly more highly in ABC-DLBCL compared with GC-DLBCL (Figure 8). This adds to previously published data that both STAT3 and IL10RA are found in significantly greater amounts in ABC-DLBCL (7, 29).

DISCUSSION

Burkitt lymphoma cell lines have been useful in determining mechanisms of action and gene targets of BCL6 (18, 39-41). Both BCL6 (42, 43) and the genes whose transcription it directly inhibits (3, 7, 8) are potential targets for therapy in DLBCL. In order to produce a model system for the systematic evaluation of BCL6 and BCL6 regulated pathways for therapy we produced a conditional BCL6 deficient Burkitt lymphoma cell line, which reproduces the functional effect of BCL6 on DNA damage responses (23) and many of the gene expression changes known to be due to BCL6. This novel cell line has significant advantages over previous methodologies (18) because minimum perturbation is required to suppress BCL6.

BCL6 deficiency suppressed proliferation of DG75-AB7 and reduced the surviving fraction of cells but, similar to work using a peptide inhibitor to abrogate BCL6 function in a Burkitt lymphoma cell line (44), about 50% of cells remain viable. We wondered whether specific pathways, normally repressed by BCL6, became active under these conditions to maintain survival. Others have shown that genes normally repressed by BCL6 can contribute to survival specifically in ABC-DLBCL (7). In order to reveal pathways required for survival of BCL6 deficient DG75-AB7, which might prove to be important in ABC-DLBCL, we carried out a synthetic lethal screen of DG75-AB7 against a library of small molecule inhibitors, many of which are in clinical use or candidates for clinical use, and sought a reduction in the surviving fraction of cells, which was greater than that produced by BCL6 deficiency alone.

Several agents from the library screen were found to enhance the effects of BCL6 deficiency. We chose to focus on lestaurtinib, a JAK2 inhibitor. JAK2 is activated in DLBCL (36) but has not previously been reported to be a direct target of BCL6 transcriptional repression. We produced several lines of evidence to support a direct effect of BCL6 on JAK2: 1) JAK2 mRNA levels increased in response to BCL6 deficiency, 2) BCL6 bound to the JAK2 promoter in vivo and in vitro and 3) a BCL6 binding site in the JAK2 promoter region was required for BCL6 mediated repression in luciferase reporter assays.

We demonstrated that STAT3, a major target of phosphorylation by JAK2, was induced and phosphorylated in BCL6 deficient DG75-AB7. STAT3 mRNA expression is directly repressed by BCL6 and BCL6 also represses IL-6 production in macrophages to inhibit STAT3 signalling (45), but a role for BCL6 in regulating JAK2 has not previously been demonstrated. JAK-STAT signalling has been investigated in DLBCL: this pathway can be activated by IL-10 (36) and by diverse genetic mechanisms such as aberrant MYD88 signalling (6) or inactivating mutation of SOCS1 (46). Overall there may be constitutive STAT3 signalling in ~50% of DLBCL (3, 7) but activating mutations of JAK2 appear to be very rare and mechanisms for JAK2 activation in DLBCL other than activating mutations have been suggested (47). Here we show that JAK2, like STAT3, is a direct BCL6 target gene in a Burkitt lymphoma cell line and this raises the possibility that BCL6 contributes to the overall regulation of JAK2-STAT3 signalling.

It was surprising that JAK2 was not only increased in amount on induction of BCL6 deficiency in DG75-AB7 but was also phosphorylated. We noted that IL10RA mRNA increased on induction of BCL6 deficiency in DG75-AB7, showing that it is directly or indirectly regulated by BCL6 (Table 2), and we wondered whether engagement of this receptor could mediate JAK2 phosphorylation.

Experiments with IL10RA blocking antibodies supported the notion that BCL6 deficiency activated an IL10RA/JAK2/STAT3 pathway.

Our data suggested that an IL10RA/JAK2/STAT3 pathway is repressed by BCL6. IL10RA, JAK2 and STAT3 have been shown separately to be...
components of pathways that are specifically active in ABC-DLBCL. Both STAT3(7) and IL10RA(29) have been suggested as targets for therapy in ABC-DLBCL and ABC-DLBCL cell lines are more sensitive to JAK2 inhibition than GC-DLBCL cell lines(3). In addition high serum IL10 levels carry a poor prognosis in DLBCL(36). Through our work we are able to link this disparate data to show that there is a role for BCL6 in the regulation of all these genes. Therefore, BCL6 appears to repress a survival pathway in ABC-DLBCL and systematic future studies of BCL6 target genes might reveal other important survival mechanisms in ABC-DLBCL.

There has been interest in employing JAK2 inhibitors in DLBCL(48, 49) but the place of these agents has not been defined. We suggest that they might be useful adjuncts to conventional treatment in cases of ABC-DLBCL expressing relatively low levels of BCL6 and that BCL6 mRNA expression might be a component of a biomarker panel to predict patient populations that will benefit from these drugs.

**EXPERIMENTAL PROCEDURES**

**Construction of DG75-AB7**

Both BCL6 alleles of the parental EBV negative Burkitt lymphoma cell line, DG75-354 (gift of Dr. Berthold Henglein), which contains a tetracycline transactivator, were disrupted by homologous recombination and a tetracycline repressible BCL6 cDNA was inserted to produce DG75-AB7. Exon 3, which contains the translation start site of BCL6 was disrupted (Figure 1A and 1B). The targeting construct contains a zeocin (zeo) resistance cassette that is flanked, by loxP sites followed by a downstream SphI site with flanking arms of homology targeting it to the BCL6 gene. The construct contains a unique KpnI restriction site facilitating linearisation prior to gene targeting. Following transformation of the parent DG75-354 cells i.e. DG75 containing a tetracycline transactivator construct, with this construct and subsequent selection in zeocin; targeted integration events were detected by PCR screening and confirmed by Southern blotting. Gene disruption was targeted to the 11763 bp genomic SphI fragment, which flanks exon 1b and finishes in exon 6. The arms of homology were sub cloned as a smaller fragment derived from this initial big construct. This 10 kb region was amplified from genomic DNA. This 9992 bp KpnI/SacII fragment was ligated into pBluescript KS+ (Stratagene), resulting in vector p10kb-homology. The 8918 bp Apal/EagI fragment of p10kb-homology was then subcloned from p10kb-homology into pBluescript KS+ generating p8.9kb-homology. For disruption of the BCL6 allele, a zeocin cassette was inserted into the Shfl site of p8.9kb-homology (end of exon 3). This 1245 bp zeocin cassette (including its promoter) was amplified from pCMV/Zeo utilising primers adding loxP sites to both ends of the zeocin cassette and an SphI restriction site to its 3' end. This Shfl-digested product was cloned into the Shfl site of p8.9kb-homology to generate the final targeting construct pTarg-BCL6. The orientation of the zeocin cassette was verified by restriction enzyme digestion and the region surrounding the 5' loxP site was sequenced. After targeting of the first BCL6 allele, cells were transiently transfected with Cre-recombinase (pMC-Cre kindly supplied by H. Gu, University of Köln), which excised the region between the loxP sites. The premature stop codon generated by targeted BCL6 gene disruption is likely to result in the mRNA being degraded by nonsense mediated decay. The potential translation of the message would result in a 55 aa truncated protein which is expected to be non functional and quickly be degraded. Once the zeocin cassette and resistance is lost, the same targeting construct was used to knockout the second allele.

**Gene Expression Analysis**

Gene expression changes due to the absence of BCL6 were measured by Affymetrix microarrays. Data is submitted to GEO with accession number GSE55301. Total RNA was extracted using RNeasy minireps (Qiagen) and 100 ng of total RNA was processed with the GeneChip® Eukaryotic Whole Transcript Sense Target Labelling Assay kit (Affymetrix, Santa Clara, CA, USA). Briefly double stranded cDNA was synthesised from total RNA using random hexamers tagged with a T7 promoter sequence and transcribed in vitro by T7 RNA polymerase to produce antisense cRNA. This was subsequently purified and used as template for a further round of cDNA synthesis. Following RNA hydrolysis, treatment of sense cDNA with uracil DNA glycosylase (UDG) and apurinic/apyrimidinic endonuclease I (APE1) fragments the DNA strand. cDNA fragments are labelled by terminal
deoxynucleotidyl transferase (TdT) with biotin and hybridised to the array (Human GeneChip 1.0 ST Array, Affymetrix), which was subsequently scanned. The quality of microarray data was evaluated by box plot and scatter plot analysis.

Real time RT-PCR - JAK2 and IL10RA mRNA levels were determined by real time PCR performed using an Applied Biosystems 7500 Real-Time PCR machine (Applied Biosystems, Foster City, CA, USA) and Taqman Universal PCR Master Mix. JAK2 primers were, forward 5'-CAGGCAACAGGAACAGATG and reverse 5'-CCATTCCCATGCAGAGTCTT. IL10RA primers were forward 5'-CAGGAAGCTGACGGATTGGGAA and reverse 5'-GCTTCAAACCACACAGACGG. Small Molecule Inhibitor Screen

DG75-AB7 was seeded at a density of 5x10^4 cells/ml in a 384 well plate, in a volume of 50µl/well on day 0 and continuously cultured in the presence or absence of doxycycline (1µg/ml) as well as a library of small molecule inhibitors (Table 1) for four days at which point cell survival was estimated. The small molecule library encompassed conventional chemotherapy and targeted therapy agents at four different concentrations. In total six replica experiments were performed with the data from the replicas combined in the final analysis. Staurosporine (10µM) was used as a positive control for the induction of apoptosis. Cell viability was estimated at the end of the experiment using the CellTiter-Glo (CTG) (Promega, Southampton, UK) luminescence assay. 20µl of CTG reagent was added to each well, the plate contents were mixed for 10 minutes at room temperature, and the luminescence measured. Each culture condition was replicated six times. Raw luminescence values were log_2 transformed and then z-score standardised according to the log_2 median effect and the variance of effects, which was estimated by calculation of the median absolute deviation (MAD).

Cell culture, growth, cell cycle, flow cytometry and DNA-double-strand break analysis

Parental DG75 cells and its derivatives were cultured in RPMI media (Life Technologies, Paisley, UK) supplemented with 10% Foetal Calf Serum (Lonza, Basel, Switzerland) and Penicillin (10,000 U/ml) (Lonza) and Streptomycin (10,000 µg/ml) (Lonza) and grown at 37 °C and 5% CO_2. Where indicated doxycycline (1 µg/ml) (D9891; Sigma, St. Louis, MO, USA) in DMSO (D2650; Sigma) was added to the culture medium. For cell culture DG75-AB7 was cultured with doxycycline for 4 days and inhibitors ruxolitinib and fedratinib (Selleck Chemicals, Houston, TX, USA) and lestaurtinib (Tocris Bioscience, Bristol, UK) were added for 24 hours.

Cells excluding trypan blue were counted and cultures were split every 2 days so that concentrations did not exceed or fall below the preferred cell density of between 1 and 9 x 10^5 cells/ml. The doubling time (T_d) between time point 1 (t_1) and time point 2 (t_2) (in hours) was calculated by inserting cell concentrations at time point t_1 (c_1) and time point t_2 (c_2) into the following formula: \[ T_d = \frac{(t_2-t_1)\ln(2)/\ln(c_2/c_1)}{c_1} \]. For cell cycle analysis, 10^6 cells were collected by centrifugation, washed once in PBS and resuspended in PBS (300 µl). Ice-cold ethanol (700 µl) was added and the fixed cells were collected by centrifugation, washed once in PBS and resuspended in 500 µl PBS containing RNase A (0.2 mg/ml) (Qiagen, Hilden, Germany) and digested at 37 °C for 1 hour. Propidium iodide was added to a final concentration of 40 µg/ml and cells were analysed by flow cytometry.

Expression of IL10RA was determined by flow cytometry (FACSCanto, BD Biosciences, Oxford, UK) utilising anti-IL10RA antibody (R&D Systems, Minneapolis, MN, USA; MAB2742) in the presence of human Fe block (BD Biosciences; 564219). Detection was with secondary anti-mouse IgG-FITC (Jackson ImmunoResearch, West Grove, PA, USA; 315-096-003). A blocking anti-IL10RA antibody (Novus Biologicals, Oxford, UK; NBPI-42534) was employed at 5 µg/ml to demonstrate functional effects. IL10 (R&D Systems) was employed at 10 ng/ml.

DG75-AB7 cells were cultured for 4 days in the presence or absence of doxycycline following which DNA-double-strand breaks were induced by irradiation at a dose rate of 1 Gy/min, at 250 kV constant potential and HLV of 1.5 mm Cu, (Pantak Industrial X-ray machine, CO, USA). 2 hours after irradiation DNA-double-strand breaks were identified using fluorescent detection of the phosphorylated form of H2AX (γH2AX). 5x 105 cells were fixed using ice cold ethanol for at least 24 hours at 4 °C and then permeabilised with 0.1%
Triton X 100 on ice for 10 mins with 0.2 mg/ml RNase (Sigma; R6513) was added and cells were incubated at 37 °C for 1 hour, blocked with 4% FCS, stained with a 1:500 dilution of anti-γH2AX (Ser139) (clone JBW301; Millipore 05-636) for 2 hours on ice and then with a 1:200 dilution of secondary antibody (AlexaFluor488 goat anti-mouse IgG; Invitrogen A21121) with rotation at room temperature (in the dark) for 1 hour. After washing cells were stained with propidium iodide (0.5 µg/ml) and analysed on a FACSCanto II (BD Biosciences, San Jose, CA, USA) and characterised for cell cycle stage using FlowJo Software v7.6.4 (Treestar Inc., Ashland, OR, USA). The mean fluorescent intensity of γH2AX was determined for cells within G1 of the cell cycle.

Chromatin Immunoprecipitation

Binding of BCL6 to the JAK2 locus was analysed by ChIP (carried out as described(30)) with an anti-BCL6 antibody (N3; Santa Cruz Biotechnology, Santa Cruz, CA, USA) and the results analysed by real-time PCR. BCL6 binding to the CD20 locus was used as a control (31). JAK2 primers were forward 5'-aggctcacagactcagc-3' and reverse 5'-agtagaaagtgaggaggggtgt-3'.

Luciferase Reporter Assays

A 2.0 kb region upstream of the JAK2 transcription start site was cloned from DG75-AB7 genomic DNA. The gene was amplified by polymerase chain reaction (PCR) using MyFi polymerase (Bioline, London, UK) and the following primers: 5'-taaggtaccccttgtccaccttg-3' (forward, with a KpnI site), 5'-agcttcgaactcagc-3' (reverse, with a NheI site). The site was also cloned in the reverse orientation using the following primers: 5'-taaggtaccccttgtccaccttg-3' (forward, with a KpnI site), 5'-agcttcgaactcagc-3' (reverse, with a NheI site). The amplified product was digested with KpnI and NheI and cloned into the empty pGL4 Luciferase Reporter Vector, pGL4.10 (Promega, Fitchburg, WI, USA). Site-directed mutagenesis was performed using the QuickChange II XL kit (Agilent, Santa Clara, CA, USA) to create a mutated binding site: GGCCGAGAA. All mutations were confirmed by sequence verification. HEK-293 cells were transiently transfected with Turbofect transfection reagent (Thermo Scientific, Waltham, MA, USA) following the manufacturer’s instructions. Cells were seeded in 96-well white-bottomed plates 24hr prior to transfection. The cells were then co-transfected with BCL6-Flag expression construct (50 or 100 ng) and/or empty pGL4.10 reporter vector to 200ng total DNA. After 8hr the cells were then co-transfected with 100ng of the various reporter constructs and 100ng pGL4.73 Renilla Luciferase construct. All transfections were performed in triplicate and Luciferase activities were measured using the Dual-Glo Luciferase Assay System (Promega) 24hr after reporter construct transfection. All luminescence readings were normalised to Renilla luciferase control readings. Reporter assays (without co-transfection of BCL6 expression construct) were similarly carried out in DG75-AB7 in the presence and absence of doxycycline.

Western Blot Analysis

DG75-AB7 cells were harvested and lysed in RIPA buffer (150 mM sodium chloride, 1.0% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, 50 mM Tris, pH 8.0) containing protease inhibitors (Sigma). Protein was separated by 7.5% SDS-PAGE (Bio Rad Laboratories, Hercules, CA, USA). Gels were blotted to polyvinylidenedifluoride (PVDF) membranes and probed with antibody. Anti-ATR (Abcam, Cambridge, UK; ab4471), anti-BLIMP1 (Cell Signaling Technology, Beverly, MA, USA; #9115), anti-MYC (Cell Signaling Technology; #9402) and anti-JAK2 (Cell Signaling Technology; #3230), anti-phospho-STAT3-Tyr705 (Cell Signaling Technology; #9145) and anti-phospho-STAT3-Ser727 (Cell Signaling Technology; #9134) were all employed at 1:1000. Secondary anti-mouse IgG or anti-rabbit IgG were employed at 1:2000. Anti-STAT3 (Cell Signaling Technology; #9132) was employed at 1:2000 and secondary anti-rabbit IgG at 1:5000.

Electromobility Shift Assays (EMSA)

EMSAs were carried out utilising a LightShift Chemiluminescent EMSA Kit (Thermo Scientific, Waltham, MA, USA; 20148). EMSAs were performed using the LightShift Chemiluminescent EMSA kit (Thermo Scientific). Binding reactions, containing 20 µg of nuclear protein lysate, were preincubated for 15 min at room temperature in EMSA binding buffer (10mM Tris, 50mM KCl, 1mM DTT, 10mM MgCl2, 10µM ZnCl2, 100 µg/ml BSA, 4% Glycerol, 2 µg Poly (dI•dC))
BCL6 suppresses an IL10RA/JAK2/STAT3 pathway

before the addition of a biotin labelled probe and a subsequent 20 minute incubation at room temperature. Complexes were separated on 5% TBE polyacrylamide gels before electrophoretic transfer to nylon membranes and detection as per the manufacturer’s instructions. For specific-competition analysis a 200-fold excess of unlabelled probe was added before the pre-incubation. For super-shift analysis 2 µg of antibody was incubated with the binding reaction for 20 minutes after the pre-incubation and before addition of the labelled probe. The test probe was designed to the putative BCL6 binding site in the JAK2 promoter region (5’-ACGATTTCTAGAATAAGTG-3’). The canonical BCL6 probe FB20 was used as a positive control (5’-GAAAATTCCTAGAAAGCATA-3’).

siRNA knockdown
DG75-AB7 were transfected with siRNA directed against JAK2 (Life Technologies Ltd, Paisley, UK, # 4392420) or a negative control siRNA (#4390843) using siPORT NeoFX (Life Technologies Ltd.) following which they were cultured for 24 hours. Doxycycline was then added to half the cells, which were then cultured for a further 24 hours, harvested and CTG luminescence (Promega) was determined.

In vivo adoptive transfer
18 to 22-week old SCID-Beige mice (Charles River, Burlington, MA, USA) were inoculated subcutaneously in the flank with DG75-AB7 (1x10^7 cells in 100 µl) pre-mixed with equivalume amounts of Matrigel HC (Sigma, E1270), under general anaesthesia. Tumours were left to establish for seven days and then the mice were assigned to one of four groups (n=8). Group 1 received no treatment and regular drinking water and provides a baseline for tumour development and morphology. Group 2 received doxycycline (Sigma D9891) in the drinking water at 1 mg/ml. Group 3 received regular drinking water and once daily subcutaneous injections of Lestaurtinib (10 mg/kg) and Group 4 received doxycycline in the drinking water (as before) in combination with once daily subcutaneous injections of lestaurtinib (10 mg/kg).

Lestaurtinib (LC Laboratories, Woburn, MA, USA) was resuspended to a final concentration of 5 mg/ml in 40% PEG100 (Sigma 76293), 10% Povidone C30 (Sigma P2472) and 2% Benzyl alcohol (Sigma 402834). Lestaurtinib was administered for 5 days out of 7 (Monday to Friday) only. Due to some skin sensitivity the injection sites were rotated between the scruff and flanks.

All groups received water ad libitum and the mean water intake per mouse was calculated (6.5 ml/mouse/day) corresponding to a mean dose of doxycycline ~300 mg/kg/mouse/day. No differences in fluid intake were noted between the groups. Animals were typically caged in single sex pairs, in conditions appropriate for immune deficient mice (irradiated diet and bedding). Following tumour initiation body condition and tumour volumes were recorded daily and water intake was monitored weekly. Tumor growth was monitored by measurement of the length (L) and the width (W) with Vernier calipers. Tumor volume was calculated by the formula: volume = W^2x0.5L.

When tumour volumes in two or more of the control mice exceeded 10 mm in size (in more than 2 dimensions) the experiment was terminated (under veterinary advice). Body mass and tumour mass measurements were made and tissues collected from all mice from all groups. All animal procedures were carried out in the Central Research Facility, University of Leicester, under the UK Home Office Licence Number PPL60/4399 and following NCRI guidelines with regard to maximum permissible tumour size.

Spleen samples formalin fixed (10% neutral buffered formalin), dehydrated (70% ethanol) and impregnated with wax, 4 µm sections were cut (following standard protocols). Staining with haematoxylin and the eosin was performed using Shandon Varistain staining machine according to the manufacturer’s instructions.

The sections were dewaxed in xylene and rehydrated in alcohol. Antigen retrieval was carried out using a high-temperature unmasking technique with diaminobenzidine chromagen solution (DAKO) high pH target retrieval solution in the microwave. Sections were quenched with peroxidase block and sections were incubated with the monoclonal anti-BCL6 or anti-Ki-67 antibodies (DAKO) (1/10 dilution in TBS) for 45 min, rinsed with TBS/Tween buffer followed by incubation with the HRP-labelled polymer for 45 min and counterstaining with haematoxylin.
BCL6 suppresses an IL10RA/JAK2/STAT3 pathway

ACKNOWLEDGMENTS
Work was supported by a grant from Leukaemia and Lymphoma Research to SDW. A Gordon Piller Leukaemia and Lymphoma Research PhD Studentship to SDW and ACGP supported JZ and a University of Leicester PhD Studentship supported SEE. RLA is supported by a Clinical Research Fellowship from the Ernest and Helen Scott Haematology Research Institute. Kate Lee (B/BASH, University of Leicester) provided bioinformatic support. We are grateful to Dr. Berthold Henglein, CNRS UMR 7098, Université Pierre et Marie Curie, Paris, France for the gift of DG75-354 and to Drs. Katerina Hatzi and Ari Melnick for making ChIP-seq data available.

CONFLICT OF INTEREST
The authors declare that they have no conflicts of interest with the contents of this article.

AUTHOR CONTRIBUTIONS
RCB, DB, SEE, JZ, RLA, ALW, LL and RE carried out experiments and analyzed data. MB carried out bioinformatic analysis. ACGP, CJL, AA and SDW analyzed data and wrote the manuscript.

BCL6 suppresses an IL10RA/JAK2/STAT3 pathway

Rosenwald, A., Wright, G., Chan, W. C., Connors, J. M., Campo, E., Fisher, R. I., Gascoyne, R. D., Muller-Hermelink, H. K., Smeland, E. B., and Staudt, L. M. (2002) The use of molecular profiling to predict survival after chemotherapy for diffuse large B-cell lymphoma. N Engl J Med. 346, 1937–1947

FIGURE LEGENDS

Figure 1
A conditional BCL6 deficient human B-cell line. (A) Scheme of disruption of the endogenous BCL6 loci of DG75. A zeocin resistance cassette flanked by loxP sites was inserted into exon 3 of the BCL6 gene, containing the initiation codon by homologous recombination. After Cre recombinase mediated removal of the antibiotic resistance gene the process was repeated on the second BCL6 allele. (B) Southern demonstrating disruption of the endogenous BCL6 loci and presence of the inserted BCL6 transgene. Genomic DNA was digested with SphI and probed with labelled probes A and B. Wild-type cells (BCL6+/+, lane 1) give an 11.8 kb band. Following the first round of targeting and before removal of the zeocin resistance cassette (BCL6+-Zeo+, lane 2) the 11.8 kb band is present with 7.9 kb and 5.1 kb bands from the targeted locus. After removal of the zeocin resistance cassette but before targeting of the second locus (BCL6+-, lane 3) 11.8 kb and 5.1 kb bands are present. Following insertion of the BCL6 transgene and targeting of the second locus (BCL6+/Zeo0+pTRE-BCL6HA, lane 4) the 11.8 kb band is no longer present, bands of 7.9 kb and 5.1 kb from the disrupted BCL6 loci are present together with a band of 4.1 kb from the BCL6 transgene. (C) Growth curves (cumulative doublings) of wild-type DG75 (WT) and three targeted clones (AB7, CD9 and FA8) in the absence (solid line) and presence (dotted line) of doxycycline. (D) Western showing BCL6 expression in DG75-AB7 in the presence and absence of doxycycline. BCL6 expression in the DLBCL cell line, SUDHL4 (BCL6 expressing), and HEK293 cells (BCL6 non-expressing) are also shown. (E) The effects of doxycycline on proliferation are reversible. DG75-AB7 cells were cultured in the presence or absence of doxycycline or with doxycycline for various times (2, 4 or 6 days) before exchanging with culture medium lacking the antibiotic. Proliferation rate (cumulative doublings) were normalized to proliferation of cells cultured without doxycycline.

Figure 2
Characterisation of DG75-AB7. (A) BCL6 deficiency causes a defect in proliferation. Wild-type DG75 (WT) and DG75-AB7 (AB7) were loaded with CFSE and fluorescence was measured in the absence (black line and text) or presence (red line and text) of doxycycline over the course of 7 days. Fluorescence histograms are presented. Mean fluorescence intensity is indicated in the top left corner. (B) Surviving fraction of DG75-AB7 following culture with doxycycline measured by a luminescence cell viability assay and cell cycle changes following culture of DG75-AB7 in the absence (-) or presence of doxycycline (Do). Cells were stained with propidium iodide and cell cycle analysis carried out with FlowJo Software. (C) Western demonstrating changes in expression of BCL6 target gene, ATR on culture of DG75-AB7 with doxycycline (Do). DNA repair capacity in DG75-AB7 is repressed by BCL6. Levels of phosphorylated H2AX following X-irradiation in either the absence (red bars) or presence (blue bars) of doxycycline were determined by flow cytometry (n=3). H2AX levels specifically in G0/G1 of the cell cycle are presented. There are significant differences in levels of phosphorylated H2AX (Mann-Whitney U-test) at 1 Gy (P=0.003) 2 Gy (P= 0.007) and 4 Gy (P=0.01).

Figure 3
Validation of microarray results by RT-PCR of 14 selected genes. Primer sequences are presented in Table 3. RT-PCR was carried out from cDNA produced from DG75-AB7 cultured in the presence (+Dox) or absence (-Dox) of doxycycline (1 µg/ml) for 96 hours. cDNA dilutions of 1, 1:5, 1:25 and 1:125 (left to right as indicated by the black triangles) were prepared and used as template for the PCR. Columns to the right show the fold induction obtained for each gene from the microarray results and the corresponding inductions calculated from the RT-PCR. Conditional formatting indicates induced genes (red) and repressed genes (blue) (Microsoft Excel v14.4.7).
BCL6 suppresses an IL10RA/JAK2/STAT3 pathway

Figure 4
Small molecule inhibitor screen for enhanced loss of viability in BCL6 deficient DG75-AB7. (A) Overview of the screen. Standardized values (drug effect z-score), calculated from x (log2 median raw value), µ (log2 median plate raw values) and σ (standard deviation of differences between log2 raw values in the presence and absence of doxycycline) according to the formula, z-score = (x - µ)/σ, are plotted for negative controls (DG75-AB7 cells in the absence or presence of doxycycline but without any of the screening agents) and positive controls (DG75-AB7 cells in the absence or presence of doxycycline and with the potent kinase inhibitor, staurosporine (10 µM), to induce apoptosis). For the test samples, standardized values for each agent and at each concentration are shown. (B) Effect of agents with z-scores ≤ -2 (Table 1) on cell survival determined by ATP luminescence. Survival of cells without doxycycline (solid line) or with this agent (dotted line) at four concentrations (1, 10, 100 nM and 1 µM) is shown. Lestaurtinib was employed at 0.2, 2, 20 and 200 nM. (C) By contrast, doxorubicin and flavopiridol reduce survival of both BCL6 replete and deficient DG75-AB7 cells whilst cyclophosphamide and olaparib have no effect on survival.

Figure 5
BCL6 deficiency leads to both transcriptional increase in JAK2 and STAT3 phosphorylation. (A) mRNA levels of JAK2 determined over 4 days in the presence of doxycycline relative to JAK2 levels in DG75-AB7 cultured without doxycycline. (B) JAK2 protein levels determined by western in DG75-AB7 after culture for 4 days with doxycycline (Dox). (C) JAK2 inhibitors suppress STAT3 phosphorylation. Westerns showing expression of phosphorylated JAK2 and phosphorylated STAT3 in DG75-AB7 in the absence (-Dox) and presence (+Dox) of doxycycline and following treatment with lestaurtinib (200 nM), fedratinib (2 µM) and ruxolitinib (200 nM). (D) Specific phospho-tyrosine-STAT3 expression. Westerns showing expression of phosphorylated STAT3-tyrosine705 (pY-STAT3), phosphorylated STAT3-serine727 (pS-STAT3), total STAT3 and BCL6 in the presence or absence of doxycycline (Dox) or lestaurtinib (Le) as indicated. (E) JAK2 siRNA knockdown. DG75-AB7 were mock transfected (lanes 1 and 4), transfected with a JAK2 siRNA (lanes 2 and 5) or a scrambled (scr) negative control siRNA (lanes 3 and 6) in the absence (lanes 1 to 3) or presence (lanes 4 to 6) of doxycycline. Cell lysates were harvested 48 hours after transfection and 24 hours after the addition of doxycycline. (F) Relative viability compared to mock transfected cells without doxycycline. Column numbers are as in (E) above. (G) Induction of IL10RA mRNA following repression of BCL6 in DG75-AB7. (H) Histograms showing IL10RA expression by flow cytometry on DG75-AB7 in the presence (+Dox) or absence (-Dox) of doxycycline. Light grey indicates isotype control and dark grey anti-IL10RA. (I) Effects of IL-10 and blocking anti-IL-10 antibody on STAT3 phosphorylation. DG75-AB7 was cultured in the presence of doxycycline and IL10 (10 ng/ml) in the presence of either a blocking anti-IL10RA antibody (5 µg/ml) or an isotype control antibody. Westerns were carried out for pY-STAT3.

Figure 6
JAK2 inhibition synergises with BCL6 deficiency to cause tumour necrosis in vivo. (A) Haematoxylin and eosin stained sections of representative tumours excised from the flanks of animals receiving neither doxycycline nor lestaurtinib (-Do-Le), either agent alone (+Do-Le or -Do+Le) or both agents together (+Do+Le). Tumours were removed after 12 days of treatment. (B) Increase in tumour volume calculated as described in Materials & Methods. Data represent mean volumes ±SEM (n=8). (C) Histology and immunohistochemistry of tumours from mice treated as indicated with doxycycline (Do) or lestaurtinib (Le). The top row of photomicrographs shows haematoxylin and eosin stained sections. The middle row shows sections stained with anti-BCL6 whilst the bottom row demonstrates staining with anti-Ki-67. Insets show higher power views. (D) Numbers of Ki-67 positive and negative cells were counted in six high power fields of sections from 4 mice from each experimental group. Mean percentage (±SEM) of Ki-67 negative cells is shown.
Figure 7
BCL6 suppresses an IL10RA/JAK2/STAT3 pathway

JAK2 is a direct BCL6 target gene. (A) BCL6 binding sites in the JAK2 promoter with positions relative to the transcription start site. (B) In vitro binding of BCL6 to the JAK2 BCL6 binding sequence. Gel shift assay were carried out with lysates from DG75-AB7 cells in the absence of doxycycline and labelled JAK2 BCL6 binding sequence oligonucleotide (J2B6BS) (50 fmol). Addition of a super-shifting anti-BCL6 antibody (aBCL6) caused disappearance of the specific band and formation of the specific BCL6-DNA complex was effectively competed by unlabelled FB20 (a consensus BCL6 binding site 7) and also by J2B6BS. Non-specific (ns) bands that were neither super-shifted nor competed by unlabelled oligonucleotide were observed. (C) ChIP-seq demonstrating in vivo BCL6 binding at the JAK2 locus of the OCI-Ly1 diffuse large B-cell lymphoma cell line employing data from 37. Gray bar indicates the peak of BCL6 and BCOR binding at the proximal promoter region. (D) Zoom-in view of the ChIP-seq data to demonstrate the BCL6 binding site (B6BS). (E) Single site ChIP assay. ChIP was carried out with anti-BCL6 and anti-actin antibodies followed by real-time PCR for the BCL6 binding site at the JAK2 locus and a site at the CD20 locus, which does not bind BCL6. Fold enrichment is compared between anti-BCL6 and anti-actin antibodies. (F) Luciferase reporter assays. HEK293 cells were transfected with 0, 50 or 200 ng of a mammalian expression vector bearing full-length BCL6 cDNA (as indicated by the black triangles) and luciferase vectors bearing either 2 kb of the proximal JAK2 promoter (WT) or this region with mutations of the BCL6 binding site 1 (Mut) or a vector bearing a luciferase gene without any inserted promoter sequence (Ctrl). Each experiment (n=3) was carried out in triplicate. For WT, Mut and Ctrl results are normalised to the condition without transfected BCL6 expression vector. There are significant differences (paired t-test) between mutated and wild-type JAK2 promoter sequences for both 50 ng (P=0.015) and 200 ng (P=0.03) of transfected BCL6 expression plasmid. (G) Luciferase reporter assay. DG75-AB7 were transfected with luciferase reporter constructs, as before. Cells cultured in the presence of doxycycline showed significantly enhanced (paired t-test; P=0.02) reporter activity. (n=3).

Figure 8
BCL6, JAK2, STAT3 and IL10RA expression levels based on previously published gene expression profiling of cases of diffuse large B-cell lymphoma(50). The signal values for BCL6 (probe 24429), STAT3 (probe 31469), JAK2 (probe 17330), IL10RA (probe 34420) were retrieved for 71 ABC-DLBCL and 110 GCB-DLBCL samples. The data had been previously log2 transformed and median centered for each gene across the entire sample set. The P values are calculated by nonparametric Mann-Whitney (U-test) to compare the values between the two DLBCL subgroups. Bars indicate the group medians.
methoxyestradiol, dasatinib, canertinib, lestaurtinib, paclitaxel and sunitinib (indicated by brown bar to right of table). z-scores of -2 or less at one concentration only were

doxycycline and the surviving fraction was measured. Drug-effect z-scores were calculated. Standardized value (drug effect z-score) is calculated from x (log2 median raw

Small molecule inhibitor screen. Compounds at concentrations from 1 nM, 10 nM, 100 nM and 1000 nM were administered to DG75-AB7 in the presence or absence of

Table 1

| Concentration (nM) | 1 | 10 | 100 | 1000 |

Table 2

Genes whose expression altered ≥0.5-fold or ≤0.5-fold, at one or more time-points following the addition of doxycycline. Fold change in expression compared to baseline conditions is presented as fold change at 16, 48 and 96 hours. For several genes e.g. CCL3L1 and TAP1, multiple probes are present on the Affymetrix chip and all data is presented in the table. Conditional formatting is employed such that induced gene expression is coloured red and repressed expression is coloured blue.

| Cluster ID | Gene Symbol | Normalised Cluster ID | Timepoint | Fold Change |

Table 4
Transcriptional regulation of genes following the addition of doxycycline to DG75-AB7. Fold induction of mRNA levels at 16, 48 and 96 hours following doxycycline treatment are shown. Individual values were colour coded utilising a conditional formatting tool (Microsoft Excel v14.4.7) with the scale being from red (the highest value) to white (the lowest value). BCL6 target genes were defined by two alternative approaches. (A) genes determined experimentally to be functional BCL6 targets18, and (B) A set of genes for which BCL6 binding to the gene locus has been experimentally ascertained by ChIP-chip (34). In both tables genes are ordered such that the least transcribed (defined by normalized Affymetrix values) is at the top and the most transcribed at the bottom. Only CCL3 is present in both tables.

Table 5
Statistical summary of ChIP enrichment at the JAK2 locus from GEO data, GSE29282 (37). The statistical test used compares each sample to the reference using a one-tailed binomial test. A false discovery rate of 0.001 is also applied. Partek® Genomics Suite® software version 6.6 Copyright ©; 2014 (Partek Inc., St. Louis, MO, USA) was employed to do the analysis. Absolute signal (read number) and computed significance of enrichment (P value), are presented.

| Antibody                              | BCL6       | BCOR       |
|---------------------------------------|------------|------------|
| Scaled fold change (CHIP vs INPUT)    | 33.23      | 10.8       |
