Abstract: The ACl-ThCl\(_4\) (A = Li, Na, K) systems could be of relevance to the nuclear industry in the near future. A thermodynamic investigation of the three binary systems is presented herein. The excess Gibbs energy of the liquid solutions is described using the quasi-chemical formalism in the quadruplet approximation. The phase diagram optimisations are based on the experimental data available in the literature. The thermodynamic stability of the liquid solutions increases in the order Li < Na < K, in agreement with idealised interactions and structural models.

Keywords: thorium; thorium tetrachloride; molten salt reactor; CALPHAD; quasi-chemical formalism

1. Introduction

Glenn Seaborg called the discovery of \(^{232}\)Th being a fertile isotope, yielding fissile \(^{233}\)U after neutron absorption and subsequent decay, ‘a fifty quadrillion discovery’ [1]. That notwithstanding, industrial use of thorium is still virtually non-existent in modern-day society. If it is to fulfill its potential as a vastly abundant energy source, reactor and fuel cycle designs are needed that are optimised for the efficient breeding and utilisation of \(^{233}\)U. Studies have shown that thorium can be used in a wide variety of reactors [2]. Therefore it is important to continue characterizing the thermophysical properties of the chemical forms it may take as an advanced nuclear fuel, e.g., metallic, oxide, nitride, or halide. As part of that effort, a thermodynamic description of the binary systems ACl-ThCl\(_4\) (A = Li, Na, K) is presented herein, since these are systems from which metallic thorium powder may be produced [3], and because they may be part of a fuel matrix in a molten salt reactor (MSR) [4]. Metal chlorides are receiving increasing attention in the MSR community, as they allow high loading of actinides compared to the more studied fluorides, although they are best suited for fast neutron systems.

Even though it has been the subject of several studies, ThCl\(_4\) is not fully characterised. It has been reported to crystallise in two phases. The low-temperature phase is tetragonal in space group \(I4_{1}a\), while the high-temperature phase belongs to space group \(I4_{1}amd\) [5]. The latter phase is metastable below the phase transition temperature, 679 K, and it is the one usually reported by experimentalists [6–11]. The low-temperature phase has only been isolated by Mason et al. [12], who used a very slow cooling rate. For this reason, the recommended thermodynamic data in the literature is for the high-temperature polymorph. The value of the standard enthalpy of formation recommended by Fuger et al. [5] is an average of values determined via solution calorimetry [13–15]. The standard entropy was estimated by Konings considering lattice and electronic contributions [16], and the high-temperature heat capacity was estimated by Rand [17]. Intriguingly, there could also be a very low-temperature phase, below 70 K [18].

Some studies for the ACl-ThCl\(_4\) (A = Li, Na, K) binary phase diagrams are available in the literature. However, despite this and their apparent simplicity compared to their fluoride counterparts, their topology is not well-established. In the LiCl-ThCl\(_4\) system, Oyamada found no intermediate phase [19], yet Vokhmyakov et al. [20], Tani [21],...
and Vdovenko et al. (original work not available to us, but described in *The Chemistry of Actinide and Transactinide Elements* [22]) [23] observed an incongruently melting compound of composition Li₄,ThCl₈. In the NaCl-ThCl₄ system, all available sources agree on the existence of Na₂,ThCl₆ and no other compound, but Vdovenko et al. [23] observed Na,ThCl₅ instead. Finally, in the KCl-ThCl₄ system, different groups report the existence of K₃,ThCl₇, K₂,ThCl₆, and K,ThCl₅. The observations are summarised in Table 1.

**Table 1.** Phases occurring in the alkali thorium chloride binary systems according to different sources.

| System        | Compounds          | References         |
|---------------|--------------------|--------------------|
| LiCl-ThCl₄    | Li₄,ThCl₈          | [20,21,23]         |
|               | none               | [19]               |
| NaCl-ThCl₄    | Na₂,ThCl₆          | [19–21]            |
|               | Na,ThCl₅           | [23]               |
| KCl-ThCl₄     | K₃,ThCl₇           | [19,24]            |
|               | K₂,ThCl₆           | [21,24]            |
|               | K,ThCl₅            | [19,24]            |

From these mixed accounts, it can be seen that there is a need for a comprehensive study to establish a coherent description of these phase diagrams. An interpretation of their most likely topology is put forward in this work, and CALPHAD models for their calculation are presented.

### 2. Thermodynamic Modelling

#### 2.1. Pure Compounds

The thermodynamic assessments were performed with the Factsage software [25] (Version 7.2). A thermodynamic assessment consists of optimising unknown parameters related to the Gibbs energy functions of all the phases occurring in a system, in order to develop a thermodynamic model consistent with experimentally determined information such as phase diagram equilibria, thermodynamic data, enthalpies of fusion, vapour pressures, and activities. The Gibbs energy function of a pure end-member in a system is given by:

$$G^0(T) = \Delta f H_{m}^0(298) - S_{m}^0(298)T + \int_{298}^{T} C_{p,m}(T)dT - T \int_{298}^{T} \frac{C_{p,m}(T)}{T}dT$$

where $\Delta f H_{m}^0(298)$ is the standard enthalpy of formation, and $S_{m}^0(298)$ is the standard absolute entropy, both evaluated at a reference temperature, typically taken to be 298.15 K (denoted here as 298 K for simplicity). $C_{p,m}$ is the isobaric heat capacity expressed as a polynomial:

$$C_{p,m}(T) = a + bT + cT^2 + dT^{-2}$$

Isobaric heat capacity data is only available for the end-members. To estimate the heat capacities and standard entropies of intermediate compounds, the Neumann-Kopp rule [26] was applied.

The thermodynamic functions of LiCl(cr,l) and KCl(cr,l) were taken from the SGPS [27]. Those of NaCl(cr,l) were taken from the IVTAN tables by Glushko et al. [28], while the heat capacity of NaCl(l) was recently recommended by van Oudenaren et al. [29]. The authors critically reviewed the four studies available on the determination of the heat capacity of NaCl(l) [30–33] and found that there was no discrepancy between the data by Dawson et al. [33] and the rest of the authors, in contrast with what Glushko et al. had argued. Considering the average of the four studies, van Oudenaren et al. recommend (68 ± 1) kJ·mol⁻¹ in the 1074 to 2500 K range. In the case of ThCl₄(cr,l), the data used were recommended by Fuger et al. [5] and Capelli and Konings [34]. As mentioned in the introduction, ThCl₄ crystallises in two phases. Using an adiabatic calorimeter, Chiotti et al. [35] measured an enthalpy of transition equal to $(5.0 \pm 1.5)$ kJ·mol⁻¹ at $(679 \pm 2)$ K. Taking
the heat capacity of ThCl$_4$-α (the low-temperature phase) to be equal to that recommended for ThCl$_4$-β (the high-temperature phase), the standard enthalpy of formation and standard entropy of ThCl$_4$-α were optimised in this work, such that the transition between both phases matched the values reported by Chiotti et al. [35]. The enthalpy of fusion (61.5 ± 5.0) kJ·mol$^{-1}$, melting temperature (T = 1042 K), and heat capacity recommended by Capelli and Konings [34] were used to describe ThCl$_4$(l). The thermodynamic functions of the intermediate compounds were optimised in this work to match the experimentally determined phase diagrams as closely as possible. All values are given in Table 2.

### Table 2. Thermodynamic data for intermediate compounds used in this work for the phase diagram assessment:

| Compound       | $\Delta_f H_m^{\circ}$ (298 K)/kJ·mol$^{-1}$ | $S_m^{\circ}$ (298 K)/(J·K$^{-1}$·mol$^{-1}$) | $C_{p,m}(T/K)$/(J·K$^{-1}$·mol$^{-1}$) = a + b·T + c·T$^2$ + d·T$^{-2}$ | Range | Reference |

### 2.2. Liquid Solution

The excess Gibbs energy terms of liquid solutions were modelled using the modified quasi-chemical model in the quadruplet approximation proposed by Pelton et al. [36]. This formalism is apt to describe ionic liquids like the melts examined here, as it allows to apply a quasi-chemical model in the quadruplet approximation proposed by Pelton et al. [36].

The excess Gibbs energy terms of liquid solutions were modelled using the modified quasi-chemical model in the quadruplet approximation proposed by Pelton et al. [36].

This formalism is apt to describe ionic liquids like the melts examined here, as it allows to apply a quasi-chemical model in the quadruplet approximation proposed by Pelton et al. [36].

In this formalism, a set of two anions and two cations makes up a quadruplet, taken to be the basic unit in the liquid solution, and the excess parameters to be optimised are those related to the following second-nearest neighbour (SNN) exchange reaction:

$$ (A – Cl – A) + (B – Cl – B) \rightarrow 2(A – Cl – B) \quad \Delta G_{AB/Cl} $$ (3)
where the chloride anions are represented by Cl, and A and B denote the cations. $\Delta g_{AB/Cl}$ denotes the Gibbs energy change associated with the SNN exchange reaction:

$$\Delta g_{AB/Cl} = \Delta g^0_{AB/Cl} + \sum_{i \geq 1} g^0_{jAB/Cl} X_{AB/Cl}^i + \sum_{j \geq 1} g^0_{jAB/Cl} X_{BA/Cl}^i$$

(4)

$\Delta g^0_{AB/Cl}$ and $g^0_{jAB/Cl}$ are coefficients which may have temperature dependence, but which are independent of composition. The composition dependence is specified by the $\chi_{AB/Cl}$:

$$\chi_{AB/Cl} = \frac{X_{AA}}{X_{AA} + X_{AB} + X_{BB}}$$

(5)

where $X_{AA}$, $X_{BB}$ and $X_{AB}$ represent cation-cation pair mole fractions. Finally, charge conservation over the quadruplet imposes the anion coordination number:

$$\frac{q_A}{Z_{AB/Cl}^A} + \frac{q_B}{Z_{AB/Cl}^B} = \frac{2q_{CI}}{Z_{AB/Cl}^CI}$$

(6)

where $q_i$ are the charges of the different ions, and $Z_{AB/Cl}^CI$ is the anion-anion coordination number. These were chosen to represent the composition of maximum short-range ordering, where the Gibbs energy tends to have its minimum. Typically, the point of maximum short-range ordering can be expected to lie near the lowest eutectic. The cation-cation coordination numbers are listed in Table 3.

Table 3. Cation-cation coordination numbers of the liquid solution.

| A   | B   | $Z_{AB/Cl}^A$ | $Z_{AB/Cl}^B$ |
|-----|-----|--------------|--------------|
| Li⁺ | Li⁺ | 6            | 6            |
| Na⁺ | Na⁺ | 6            | 6            |
| K⁺  | K⁺  | 6            | 6            |
| Th⁴⁺| Th⁴⁺| 6            | 6            |
| Li⁺ | Th⁴⁺| 4            | 6            |
| Na⁺ | Th⁴⁺| 3            | 6            |
| K⁺  | Th⁴⁺| 4            | 6            |

The optimised excess Gibbs energy parameters of the binary liquid solutions are shown in Equations (7)–(9). The parameters were optimised based on the phase diagram equilibria points of the liquidus.

$$\Delta G_{LiTh/Cl} = -8000 - 3600 \cdot \chi_{LiTh/Cl} - 7300 \cdot \chi_{ThLi/Cl} \text{ J} \cdot \text{mol}^{-1}$$

(7)

$$\Delta G_{NaTh/Cl} = -27,700 - 7500 \cdot \chi_{NaTh/Cl} - 14,000 \cdot \chi_{ThNa/Cl} \text{ J} \cdot \text{mol}^{-1}$$

(8)

$$\Delta G_{KTh/Cl} = -40,000 - 10,000 \cdot \chi_{ThK/Cl} \text{ J} \cdot \text{mol}^{-1}$$

(9)

3. Results and Discussion

3.1. Phase Diagrams

The calculated phase diagrams are shown in Figures 1–3, and invariant equilibria are listed in Table 4. For the LiCl-ThCl₄ system, the modelling choice to include Li₄ThCl₈ was very clear: three different authors reported they had observed it. Incidentally, in the LiCl-UCl₄ phase diagram there is also a ternary chloride, although the formula is Li₂UCl₆ [42]. It has been determined to belong to space group $P6_3/mmc$ [43]. The calculated phase diagram closely reproduces the equilibria found by Tanii [21]. The melting points of the end-members measured by Tanii agree well with the recommended values, indicating quite pure reagents. Oyamada [19], on the other hand, reports melting points for the
end-members which are more than 20 K higher, which could be due to oxygen or water contamination. It can be seen that the $\alpha - \beta$ transition of ThCl$_4$ is very close to the eutectic of the system, which would make both events very difficult to resolve experimentally.

In the NaCl-ThCl$_4$ system, the modelling choice is also clear: three authors agree that Na$_2$ThCl$_6$ forms and that it melts congruently, and only Vdovenko et al. [23] report a different stoichiometry (NaThCl$_5$). In the analogous NaCl-UCl$_4$ system a compound with formula Na$_2$UCl$_5$ was not observed, but Na$_2$UCl$_6$ was [42,44,45]. Furthermore, its crystal structure was studied and it is known to belong to space group $P-3m1$ [43]. These observations support the choice to include Na$_2$ThCl$_6$. In this phase diagram the $\alpha - \beta$ transition of ThCl$_4$ is again very close to the second eutectic of the system, making it experimentally difficult to observe.

The KCl-ThCl$_4$ system has greatest discrepancies in the 0.25 < ThCl$_4$ < 0.33 region. Gershanovich and Suglobova [24] reported both K$_3$ThCl$_7$ and K$_2$ThCl$_6$, Oyamada [19] reported only the former, and Tanii [21] and Vokhmyakov [20] reported only the latter (see Table 1). In fact, Gershanovich and Suglobova [24] characterised the crystal structure of K$_2$ThCl$_6$, which belongs to space group $Cmcm$, so this phase was retained in the assessment. Including K$_3$ThCl$_7$ raises the liquidus around the line compound and can be done without re-optimising the Gibbs energy terms of the other intermediate phases. However, much larger excess Gibbs energy parameters would need to be imposed on the liquid solution to obtain in this new optimisation the solidus temperature close to the experimental points. Relying, yet again, on what is known on the KCl-UCl$_4$ system, in which a phase with formula K$_2$UCl$_6$ was reported [42,44], the phase K$_3$ThCl$_7$ was discarded. As for KThCl$_5$, Tanii [21] is the only author who did not suggest its existence, although his calorimetric measurements form a concavity with a maximum centered around $X$(ThCl$_4$) = 0.5 (Figure 3, *), which can very well be interpreted as the congruent melting of a phase with stoichiometry KThCl$_5$. For that reason, the phase was retained in the assessment.

* Interpreted by the author to be the congruent melting of K$_3$ThCl$_7$.

3.2. Enthalpy of Mixing

The mixing enthalpies are of great interest since they are linked to the stability of the liquid solutions. They have not been measured for these systems, yet the calculated values, shown in Figure 4a (T = 1100 K), may serve as another dataset, apart from the phase diagrams, to gauge the validity of the models optimised here. There are three things to notice. First of all, the mixing enthalpies are negative at all compositions. Second, the depth of the curves increases in magnitude in the order Li < Na < K. Third, the curves are not symmetric, but display minima in the ACI-rich regions (A = Li, Na, K). Although ions do not behave like hard charged spheres [46], it may be a useful exercise to model them with such an idealised potential in order to gain insight into the energetics of mixing in the melt:

\[
V_{qq}(r_{ij}) = \sum_{i<j} \frac{q_i q_j}{r_{ij} r_{0,ij}} \quad r_{ij} > r_{0,ij} \quad (10)
\]

\[
V_{rep}(r_{ij}) = \infty \quad r_{ij} \leq r_{0,ij} \quad (11)
\]

In Equations (10) and (11), \( q \) denotes formal charge of ions \( i \) and \( j \), \( r_{ij} \) is the internuclear distance, and \( r_{0,ij} \) is the sum of the radii of ions \( i \) and \( j \). Retaining the quadruplets as a crude structural model, the energy change upon SNN exchange (Equation (3)) is:

\[
\Delta V_{SNNexchange} = 2 \frac{q_A q_{Th} + q_{Cl} q_{Cl}}{r_{ThCl_4}^2} - \frac{q_{Th} q_{Th} + q_{Cl} q_{Cl}}{r_{ThCl_4}^2} - \frac{q_A q_A + q_{Cl} q_{Cl}}{r_{ACl}^2} \quad (12)
\]

In rocksalt structures, the cation-anion coordination number is 6, and a coordination number of 6 has been seen to be prevalent about Th$^{4+}$ in LiCl-ThCl$_4$ melts with molecular dynamics (MD) simulations [47]. Taking into account the Shannon radii [48] for such coordinations, the values in Table 5 are obtained. Note that they are meant only to illustrate general qualitative trends: a quantitative description requires taking into account physically realistic structural models and multiple interactions over the long range, as in molecular dynamics simulations.
Table 5. Change in exchange energy due to SNN exchange reactions.

| Ion   | Coordination | Shannon Ionic Radius $r_i$(Å) [48] | $\Delta V_{\text{SNNexchange}}$(Hartree) |
|-------|--------------|-----------------------------------|------------------------------------------|
| Li$^+$ | VI           | 0.76                              | -4.1                                     |
| Na$^+$ | VI           | 1.0                               | -4.2                                     |
| K$^+$  | VI           | 1.38                              | -4.9                                     |
| Th$^{4+}$ | VI        | 0.94                              |                                          |
| Cl$^-$ | VI           | 1.81                              |                                          |

*Not to be confused with the cation-cation coordination number of Table 3.*

From this simplified picture, the enthalpies of mixing can be expected to be favourable from a Coulombic point of view. Moreover, Table 5 agrees with the trend of progressive stabilisation with increasing alkali radius shown by the curves in Figure 4(a). This trend is also related to an increased stability of first-nearest neighbour (FNN) shells around Th$^{4+}$ as the polarizing ability of the alkali cation diminishes with increasing size [49]. Furthermore, if the mixing event is considered as an acid-base reaction:

$$nACl + ThCl_4 = [ThCl_{4+n}]^{n-n} + nA^+$$  \hspace{1cm} (13)

the increasing radius of the alkali cation implies its charge is spread over a larger volume, resulting in a more stable conjugate chloroacid $A^+$, contributing to the overall stability of the liquid solution. The third effect, the asymmetry, is related to the choice of cation-cation coordination numbers (Table 3), chosen to reflect the compositions of the lowest-melting eutectics and maximum short-range ordering. Such an asymmetry would also be expected in experimentally measured curves. For instance, calorimetric studies of the ACI-MCl$_2$ systems ($M =$ Mn, Fe, Co, Ni, Cd; $A =$ Li, Na, K, Rb, Cs) [50–52] revealed a minimum for the enthalpy of mixing near $X$(MCl$_2$)=0.33, the stoichiometry which favours the formation of tetrahedral MCl$_{4-}$ complexes in the melt. Complexes of these kind have been observed spectroscopically in studies in which NiCl$_2$ is dissolved in alkali chlorides [53,54]. The coordination of $[ThCl_x]^{4-x}$ shells has been studied with Raman spectroscopy by Photiadis and Papatheodorou [55], and they were found to be 6 (octahedral) and 7-coordinated (pentagonal bipyramidal) in melts rich in alkali chloride ($A =$ Li, Na, K, Cs). Beyond ~0.3 ThCl$_4$ content, bridging of these shells was observed via shared chlorides, up to pure ThCl$_4$. The relatively limited stability of (ThCl$_x$) $^{4-x}$ complexes when LiCl is the solvent, compared to the other alkali chlorides would yield the most symmetric curve, as in Figure 4a. Calorimetric measurements have shown this to be the case for the (Li, Th)F$_2$ melt [56].

The thermodynamic stability of solutions is also affected by entropy effects. For example, in systems with shallow mixing enthalpies and negative mixing entropies, miscibility gaps may result, although that is more common in metallic systems [57]. In the present systems, the calculated mixing entropies of the (Li, Th)Cl$_x$ and (Na, Th)Cl$_x$ liquid solutions are positive throughout the composition range (Figure 4b), contributing to the stability of the mixtures. In agreement with the structural features just discussed, (Li, Th)Cl$_x$ tends to regular solution behaviour, and (Na, Th)Cl$_x$ deviates from regularity, showing a minimum at the point of maximum short-range ordering (SRO). (K, Th)Cl$_x$ displays such strong SRO that the entropy of mixing approaches zero at its minimum near $X$(ThCl$_4$) = 0.4: the mixing is least favourable from an entropic perspective where it is most favourable from an enthalpic point of view. However, the mixing enthalpies dominate the contribution, and the Gibbs energies of mixing which govern overall liquid phase stability are arranged in the same order (Figure 5). A high stability of the liquids is a desirable property, as it makes it more likely to find alloys which can withstand their corrosive properties, as well as contributing to their stability under irradiation [58].
Figure 4. (a) Enthalpies and (b) entropies of mixing of the (A,Th)Cl₄ liquid solutions calculated at T = 1100 K.

Figure 5. Gibbs energies of mixing of the (A,Th)Cl₄ liquid solutions calculated at T = 1100 K.

4. Conclusions

The ACl-ThCl₄ (A = Li, Na, K) systems are of metallurgical and nuclear importance. CALPHAD models have been parametrised for them, with a view to assess whether further research on these binary systems is required. The models describe the experimental phase diagrams with a good accuracy. The enthalpies of mixing substantially contribute to the thermodynamic stability of the melts, which increases in the order Li < Na < K. Strong short-range order is apparent in the calculated mixing entropy curves, which become less favourable with the increasing size of the alkali cation: (K,Th)Cl₄ even displays an entropy of mixing close to zero where the enthalpy of mixing is greatest in magnitude. The trends in the mixing properties are consistent with simple Coulombic and structural considerations of these salts in the molten state. Still, novel data on these systems are required to better ascertain their phase diagrams and thermodynamic data. Relatively easy access to β-ThCl₄ from a reaction between widely available ThO₂ and AlCl₃, has recently been described by Deubner et al. [59]. This provides an opportunity to, among other things:
• Isolate the intermediate phases Li₄ThCl₈, Na₂ThCl₆, and KThCl₅ and elucidate their crystal structures;
• Derive their standard enthalpies of formation and standard entropies;
• Obtain novel phase equilibrium data with calorimetry, particularly for the KCl-ThCl₄ system;
• Measure enthalpies of mixing for the liquid solutions.
