TWISTED DONALDSON INVARIANTS

TSUYOSHI KATO, HIROFUMI SASAHIRA, AND HANG WANG

Abstract. Fundamental group of a manifold gives a deep effect on its underlying smooth structure. In this paper we introduce a new variant of the Donaldson invariant in Yang-Mills gauge theory from twisting by the Picard group of a 4-manifold in the case when the fundamental group is free abelian. We then generalize it to the general case of fundamental groups by use of the framework of non commutative geometry. We also verify that our invariant distinguishes smooth structures between some homeomorphic 4-manifolds.

1. Introduction

Gauge theory and non commutative geometry are both the central branches of the Atiyah-Singer index theory from the view point of study on smooth structure of manifolds. Both theories gave serious developments in differential topology. In Yang-Mills gauge theory, the ASD moduli space is the core object which possesses deep topological information on the underlying 4-manifolds. The Novikov conjecture on homotopy invariance of higher signatures has been developed extensively by applying non commutative geometry. Lusztig’s approach to the Novikov conjecture was quite influential, and is a basis of successive developments of the subject [28]. This arose from study of smooth structure in high dimension, where fundamental group plays a central role in surgery theory.

It would be quite natural to try to combine both theories by introducing a unified framework to analyse smooth structure on 4-manifolds. In this paper we start constructing a twisted Donaldson invariant when the fundamental group of the underlying 4-manifold is free abelian, by combining Lusztig’s method of use of families of flat line bundles. Following Connes-Moscovici, we introduce non commutative geometry framework to generalize our construction to produce the twisted Donaldson invariant for non commutative groups. See [21] for a related work on Seiberg-Witten and Bauer-Furuta invariant.

Let $E \rightarrow X$ be an $SU(2)$ vector bundle and $\mathcal{B}^*(E)$ be the set of the gauge equivalent classes of irreducible connections on $E$. We have the universal $SU(2)$-vector bundle $E \rightarrow X \times \mathcal{B}^*(E)$.
which gives a family of bundles with connections $E_{([A])} = \mathbb{E}|_{X \times \{[A]\}}$ on $X$ and which consists of a structural framework in Yang-Mills gauge theory. (The precise construction requires more technical cares. See Section 2.)

Let $\Gamma$ be a finitely generated group, and fix a homomorphism $f : \pi_1(X) \to \Gamma = \pi_1(B\Gamma)$ which is represented by a continuous map $f : X \to B\Gamma$. Typically $\Gamma = \pi_1(X)$ and $f : X \to B\Gamma$ is the classifying map of the universal cover $\tilde{X} \to X$. Let $\rho : \pi_1(B\Gamma) \to U(1)$ be a representation. Suppose that $\Gamma$ is isomorphic to a free abelian group of rank $m$. Then $\rho$ presents a trivial line bundle $L_\rho$ with a $U(1)$ flat connection on $B\Gamma(\cong T^m)$. The set of $U(1)$ representations, denoted by Pic$(B\Gamma)$, is the moduli space of flat $U(1)$ connections. All the line bundles $L_\rho$ together form a complex line bundle

$$L \to B\Gamma \times \text{Pic}(B\Gamma).$$

Combining these two objects, in this paper we introduce deformation of the universal bundle from the view point of the fundamental group of an underlying four manifold. Suppose again that $\Gamma$ is isomorphic to a free abelian group of rank $m$. A connection $A$ on $E$ extends to a connection $A_\rho$ on $E \otimes f^*L_\rho$, passing through the homomorphism $f : \pi_1(X) \to \Gamma = \pi_1(B\Gamma)$ induced by $f$. If one considers all the irreducible connections in the same way, there is a transform

$$T_\rho : \mathfrak{B}^*(E) \to \mathfrak{B}^*(E \otimes f^*L_\rho)$$

from the set of irreducible connections on $E$ to the one on $E \otimes f^*L_\rho$. We obtain the full map if we consider all the representations

$$T : \mathfrak{B}^*(E) \times \text{Pic}(B\Gamma) \to \bigcup_\rho \mathfrak{B}^*(E \otimes f^*L_\rho).$$

Thus $\mathfrak{B}^*(E) \times \text{Pic}(B\Gamma)$ parametrizes connections on the bundles $\{E \otimes f^*L_\rho\}_\rho$. Consider the following bundle

$$\mathbb{E} \boxtimes_X (f \times \text{id})^*L \to X \times \mathfrak{B}^*(E) \times \text{Pic}(B\Gamma)$$

which consists of the family of bundles with connections $(\mathbb{E}|_{X \times \{[A]\}}) \otimes f^*L_\rho$ on $X$ parametrized by $\mathfrak{B}^*(E) \times \text{Pic}(B\Gamma)$. Here $\boxtimes_X$ denotes the fibered product over $X$. For our construction of twisted Donaldson invariants, we need a family of bundles with connections on $X \times B\Gamma$.

**Definition 1.1.** Let $X$ be a compact and spin 4-manifold and suppose that $c_2(E)$ is odd. The twisted universal bundle is defined by

$$\mathbb{E}^\text{tw} := \mathbb{E} \boxtimes_X (f \times \text{id})^*L \boxtimes_{\text{Pic}} L \to X \times B\Gamma \times \mathfrak{B}^*(E) \times \text{Pic}(B\Gamma)$$

where $\boxtimes_{\text{Pic}}$ is the fibered product with respect to the Picard group.

The conditions that $X$ is spin and $c_2(E)$ is odd are necessary for the existence of the universal bundle $\mathbb{E}$. See Lemma 5.1.

In Donaldson theory, a homomorphism

$$\mu : H_2(X; \mathbb{Z}) \to H^2(\mathfrak{B}^*(E); \mathbb{Q})$$

is given by the first Chern class of the determinant bundle of the index of the family of the twisted Cauchy-Riemann operators on an embedded surface $\Sigma$ in $X$ parametrized by $\mathfrak{B}^*(E)$. 
Let $D : \Gamma(E) \to \Gamma(F)$ be a differential operator over $X$, and $\rho : \pi_1(X) \to U(1)$ be a representation. Then one can twist $D$ with $\rho$ so that it gives another operator $D_\rho : \Gamma(E \otimes L_\rho) \to \Gamma(F \otimes L_\rho)$. This gives a family of operators
\[
\mathbb{D} := \{D_\rho\}_{\rho \in \text{Pic}(B\Gamma)}
\]
parametrized by the Picard torus. Such family of elliptic operators play the important role in Lusztig's construction.

Now take a compact submanifold $M \subset X \times B\Gamma$. Suppose the dimension of $M$ is even and $M$ is spin with the complex spinor bundle $S = S^+ \oplus S^-$ and the Dirac operator $D : \Gamma(S^+) \to \Gamma(S^-)$. A representation $\rho : \pi_1(B\Gamma) \to U(1)$ gives the flat line bundles $L_\rho$ and $f^*L_\rho$ on $B\Gamma$ and $X$ respectively. For each element $[A] \in \mathcal{B}^*(E)$, one can twist $D_A$ with the flat line bundles $L_\rho, f^*L_\rho$, and obtain the Dirac operator with coefficients
\[
D_{A,\rho} : \Gamma((S^+ \otimes E \otimes f^*L_\rho) \boxtimes L_\rho) \to \Gamma((S^- \otimes E \otimes f^*L_\rho) \boxtimes L_\rho).
\]
This gives the family of the full twist of the Dirac operators
\[
\mathbb{D}^w_M = \{D_{A,\rho}\}_{([A],\rho) \in \mathcal{B}^*(E) \times \text{Pic}(B\Gamma)}
\]
which is a basic object in our construction of the twisted Donaldson invariants.

Roughly we define the twisted $\mu$ map by
\[
\mu^w_1([M]) = \text{ch(Ind} \mathbb{D}^w_M) \in H^*(\mathcal{B}^*(E) \times \text{Pic}(B\Gamma); \mathbb{Q})
\]
where Ind $\mathbb{D}^w_M$ is the index bundle over $\mathcal{B}^*(E) \times \text{Pic}(B\Gamma)$. More precisely we have to take care of non compactness of $\mathcal{B}^*(E)$. See Section 3 for the precise construction.

In order to see that our twisted Donaldson invariants are non trivial, we induce two properties on topology of four manifolds. These were suggested by Professor K. Fukaya, to whom we are thankful.

Let $Y, Y_1, Y_2$ all be spin 4-manifolds with $b^+ > 1$. We will give concrete examples which satisfy the above conditions.

**Theorem 1.2.** Let $m \geq 0$ be a non negative integer.

1. If moreover $Y$ is simply connected, algebraic, then $X = Y \#^m(S^1 \times S^3)$ cannot admit connected sum decompositions $X = X_1 \# X_2$ with $b^+(X_1) > 0$.

2. Suppose that the Donaldson invariant over $Y_1$ vanishes but the one over $Y_2$ does not. Moreover assume that they are mutually homeomorphic so that the pair is exotic. Then the corresponding pairs $Y_1 \#^m(S^1 \times S^3)$ and $Y_2 \#^m(S^1 \times S^3)$ are also exotic.

To verify these results, we use our computations of the twisted Donaldson invariant defined as below. Let $X$ be a compact and spin 4-manifold with $b^+(X) > 1$. Put
\[
(1.2) \quad A(X) = \text{Sym}(H_0(X;\mathbb{Z}) \oplus H_2(X;\mathbb{Z})) \otimes \Lambda(H_1(X;\mathbb{Z}) \oplus H_3(X;\mathbb{Z})).
\]
In the rank 1 case $\Gamma \cong \mathbb{Z}$ ($B\Gamma \cong S^1$), for each $r \in \{1, 2, 3, 4\}$, the twisted Donaldson polynomial is formally given by the following
\[
\Psi^{tw, (r)}_{X, t} : A(X) \otimes H_{odd}(X;\mathbb{Z}) \to H^*(\text{Pic}(B\Gamma); \mathbb{Q}) \cong H_*(\Gamma; \mathbb{Q}),
\]
\[
\Psi^{tw, (r)}_{X, t}([M_1], \ldots, [M_d]; [M]) = \int_{\mathcal{M}(E)} \mu([M_1]) \wedge \cdots \wedge \mu([M_d]) \wedge \mu^t([M])
\]
if there exists an $SU(2)$-vector bundle $E$ on $X$ with $c_2(E)$ odd and with 
$\dim \mathcal{M}(E) = \sum_{j=1}^{d}(4-\dim M_j)+r$. We put $\Psi_{X,f}^{tw,(r)}([M_1], \ldots, [M_d]; [M]) = 0$, 
if there is no such $SU(2)$ vector bundle. Probably it is possible to define $\Psi_{X,f}^{tw,(r)}$ for $r \geq 5$, 
but we do not discuss in this paper.

Of course the integral above makes sense only if the cohomology class 
$\mu([M_1]) \cup \cdots \cup \mu([M_d]) \in \mu^r(M)$ has compact support since $\mathcal{M}(E)$ is not 
compact. We will overcome this issue by choosing a submanifold in $\mathcal{B}^+(E)$ dual 
to the cohomology class which behaves nicely near the end of $\mathcal{M}(E)$ as in 
the usual Donaldson theory.

We will compute $\Psi_{X,f}^{tw,(3)}$ in the case of the connected sum $X = Y \# S^1 \times S^3$. 
Let $\ell$ be a loop in $X$ which represents a generator of $\pi_1(S^1 \times S^3) \cong \mathbb{Z}$. 
We will verify the equality

$$
\Psi_{X,f}^{tw,(3)}([M_1], \ldots, [M_d], [\ell]) = -\Psi_Y([M_1], \ldots, [M_d]) \eta.
$$

Here $\Psi_Y$ is the Donaldson invariant over $Y$, and $\eta \in H^1(\text{Pic}(B\mathbb{Z}); \mathbb{Z}) \cong H^1(B\Gamma; \mathbb{Z}) \cong \mathbb{Z}$ is a generator. See Example 3.2

The above construction naturally leads to an extension to higher rank 
case of free abelian groups. We verify non triviality of such extension. In 
particular we reproduce Theorem 1.2 under the additional assumption of 
simple type, by use of the extension of the twisted Donaldson invariant.

Based on the above constructions, we generalize the twisted Donaldson 
theory to the case of non commutative fundamental groups. Immediately 
two difficulties arise, which prevent from a straightforward extension. One 
is that $B\Gamma$ is not a manifold in general. The other is that Picard group 
becomes much harder to treat in general. We shall use the spin bordism 
group $\Omega_{\text{spin}}^*(B\Gamma)$ instead of $H_*(B\Gamma; \mathbb{Z})$, which solves the former difficulty.

The latter difficulty touches the central idea of non commutative geometry. 
Let us briefly explain it. It is well known as the Swan’s theorem that 
topological $K$ group of a compact CW complex is naturally identified with the 
operator $K$ group of continuous functions over the space. Non commutative 
algebras are applied to the latter group, and this plays a role of 
a basic bridge between non commutative algebras and algebraic topology. 
Associated with the de-Rham cohomology over a space is Connes cyclic cohomology $HC^*(A)$ 
for a non commutative algebra $A$. The parallel notions have been established such as the Chern character $K_*(A) \to HP_*(A)$.

Let us describe more details on the passage from commutative to non 
commutative analysis. An important aspect is Fourier transform on tori, 
which gives the correspondence of functions between a torus and its dual torus. 
The dual torus parametrizes flat $U(1)$ connections over the torus 
called the Picard torus. Such space duality comes from a strong constraint 
that the group is free abelian. For a non commutative group $\Gamma$, there are 
no such space duality, but corresponding to the space of functions over the 
dual torus is the (reduced) group $C^*$ algebra $C^*_r(\Gamma)$ of the group, given as 
a completion of the complex group ring (see subsection 5.3). An elliptic operator twisted by every flat $U(1)$ connection over the torus produces a family of the elliptic operators parametrized by the Picard torus, as we described above. The family index gives an element of $K^0(\text{Pic}(B\Gamma))$. A non commutative interpretation is the elliptic operator with coefficient by
the Mishchenko-Fomenko flat $C^r_\ast(\Gamma)$ bundle, and its index takes a value in $K_0(C^r_\ast(\Gamma))$. In case of $\Gamma \cong \mathbb{Z}^n$, where $B\Gamma$ is the $n$-torus $T^n$, the isomorphisms hold:

$$K_0(C^r_\ast(\Gamma)) \cong K_0(C(Pic(T^n))) \cong K^0(Pic(T^n)).$$

Chern-Weil theory presents a construction of the Chern classes by smooth differential forms which take the values in the de-Rham cohomology. A key to describe its non commutative counterpart is the existence of a dense subalgebra $C^\infty(\Gamma) \subset C^r_\ast(\Gamma)$ which is closed under holomorphic calculus. The algebra plays a central role in non commutative de-Rham theory by use of cyclic cohomology. Conceptually a canonical choice of this algebra corresponds to the algebra of smooth functions on manifolds.

The Chern character is given by a map

$$Ch_\ast : K_\ast(C^r_\ast(\Gamma)) \to HP_\ast(C^\infty(\Gamma)).$$

There is a canonical map $HP_\ast(C^\infty(\Gamma)) \to H_\ast(\Gamma; \mathbb{C})$, and it induces an isomorphism

$$HP_\ast(C^\infty(\Gamma)) \otimes \mathbb{C} \cong H_\ast(\Gamma; \mathbb{C})$$

under some cohomological conditions on $\Gamma$, to be more precise, when $\Gamma$ satisfies the Baum-Connes conjecture and the Chern character $Ch_\ast$ is rationally isomorphic. Typical examples are free abelian groups. A weaker condition for $\Gamma$, called admissibility, guarantees surjectivity of the canonical map (Proposition 4.13).

Let $B \subset M(E)$ be a compact submanifold. As a canonical extension of the twisted $\mu$ map to non commutative case, we introduce the following map. Let us fix a smooth algebra $C^\infty(\Gamma)$. Then we construct a twisted $\mu$-map

$$\mu_{tw}^\mu : \Omega_x^{Spin}(X) \otimes \Omega_x^{Spin}(B\Gamma) \to HP_\ast(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B)).$$

If moreover the group is admissible, then we derive its cohomological formula which follows essentially from Connes-Moscovici’s index theorem. Put

$$A^\pi(X) = \text{Sym}(H_0(X; \mathbb{Z}) \oplus H_2(X; \mathbb{Z})) \otimes \Lambda H_3(X; \mathbb{Z}) \times \Pi_{m \in \mathbb{Z}_{\geq 0}} \pi_1(X)^{x_m}$$

where we regard $\pi_1(X)$ as just a set, rather than group. The twisted Donaldson map is given by

$$\Psi_{X,\Psi}^{tw,(r)} : A^\pi(X) \times (\Omega_x^{Spin}(X) \otimes \Omega_x^{Spin}(B\Gamma)) \to HP_\ast(C^\infty(\Gamma) \otimes C^\infty(\Gamma))$$

for $r = 1, 2$. In particular we obtain the following map

$$\Psi_{X,\Psi}^{tw,(r)} : A^\pi(X) \times (\Omega_x^{Spin}(X) \otimes \Omega_x^{Spin}(B\Gamma)) \to H_\ast(\Gamma; \mathbb{Q}) \otimes H_\ast(\Gamma; \mathbb{Q})$$

when $\Gamma$ is admissible and $HP_\ast(C^\infty(\Gamma))$ is finite dimensional. Note that when $\Gamma$ is abelian or more generally, $\Gamma$ admits a cohomological formula in the sense of Theorem 5.6, $\pi_1(X)$ can be reduced to $H_1(X; \mathbb{Z})$ and $A^\pi(X)$ can be simplified to $A(X)$ defined in (1.2).

At present we do not know how to treat non compactness of the moduli spaces in the non commutative case, which is the reason why we restrict $r \leq 2$.

The condition of $\Gamma$ being admissible touches with smooth structure on the underlying manifold. Actually it is a crucial condition to verify the Novikov
conjecture which is still open in general and is a fundamental problem in the study of high dimensional smooth structure:

**Proposition 1.3.** Let $M$ be a compact oriented smooth manifold of arbitrary dimension. If $\pi_1(M) \equiv \Gamma$ is admissible, then $\Gamma$ satisfies the Novikov conjecture on homotopy invariance of higher signatures.

In particular, the conclusion holds, if it admits a smooth algebra $C^\infty(\Gamma)$ with polynomial cohomology and rapid decay property. It has not yet been known whether each finitely presented group could satisfy admissibility, nor any counter example has been known.

From the viewpoint of study on smooth structure on four manifolds, it would be of particular interest for us to try to construct the twisted Donaldson map without the conditions on fundamental groups. There are two aspects for this. One is that in order to compute the twisted Donaldson invariant, we will have to use the Connes-Moscovici index formula which cannot be applied to a general group, and we have to assume that the group is admissible. The other is that the rational cohomology group of the configuration space is generated by the image of the standard $\mu$ map, in the case of simply connected 4-manifolds. So it makes sense to speculate that the fundamental group $\Gamma$ will appear in the generalization of the Donaldson invariant to the non-simply connected case.

It turns out that the pull backs of these maps recover the twisted Donaldson’s invariant for commutative case described above. Suppose $\Gamma \cong \mathbb{Z}^n$ is free abelian, and let $\Delta : \text{Pic}(B\Gamma) \to \text{Pic}(B\Gamma) \times \text{Pic}(B\Gamma)$ be the diagonal map. Then it induces the homomorphisms

$$\Delta_* : H_*(\Gamma; \mathbb{Q}) \otimes H_*(\Gamma; \mathbb{Q}) \to H_*(\Gamma; \mathbb{Q})$$

passing through the isomorphisms $H_*(\Gamma \times \Gamma; \mathbb{Q}) \cong H^*(\text{Pic}(B\Gamma) \times \text{Pic}(B\Gamma); \mathbb{Q})$ and $H_*(\Gamma; \mathbb{Q}) \cong H^*(\text{Pic}(B\Gamma); \mathbb{Q})$. Then

$$\Delta_*(\Psi_{X}(r)) : A(X) \otimes H_*(X; \mathbb{Z}) \otimes \Omega^*_{\text{Spin}}(B\Gamma) \to H_*(\Gamma; \mathbb{Q})$$

coincides with our twisted Donaldson invariant for commutative case.

1.1. **A conjecture.** We would like propose:

**Conjecture 1.4.** If $X$ splits into a connected sum $X = X_1 \sharp X_2$ with $b^+(X_i) \geq 1$ for $i = 1, 2$, then the twisted Donaldson invariant vanishes:

$$\Psi_{X,f}^{tw,(r)} \equiv 0.$$ 

Let us explain how to verify it for more restrictive case of groups, and how its argument breaks for more general case of groups. Actually such a restrictive case admits a cohomological formula of the twisted Donaldson invariant, which is obtained by applying the Connes-Moscovici’s index theory. They verified a fact that the Novikov conjecture is satisfied for a group if it admits such a cohomology formula. The Novikov conjecture states homotopy invariance of higher signatures and arose from study on smooth structure of high dimensional manifolds. So our vanishing conjecture can measure complexity of smooth structure from the both viewpoints of gauge theory and surgery theory.
1.1.1. **Splitting ASD moduli space.** Let $X = X_1 \sharp X_2$ be a connected sum and put $\pi_1(X) = \Gamma$ and $\pi_1(X_i) = \Gamma_i$ for $i = 1, 2$. Then $\Gamma = \Gamma_1 \ast \Gamma_2$. Let us recall Donaldson’s fundamental result (Theorem 9.3.4 of [14])

**Theorem 1.5.** Let $E \to X$ be an $SU(2)$ bundle over an oriented closed smooth 4-manifold. Suppose $X = X_1 \sharp X_2$ splits as a connected sum with $b^+(X_i) \geq 1$. Then the Donaldson invariant vanishes:

$$\Psi_X \equiv 0.$$ 

**Proof.** Let us describe the idea of the proof. Let $M(E, g)$ be the ASD moduli space over $(X, g)$. Choose a family of Riemannian metrics $g_a$ so that the neck part length grow as $[-T_a, T_a] \times S^3$ with $T_a \to \infty$. Take elements $[A_a] \in M(E, g_a)$. Then a subsequence converges to a pair of ASD solutions $(A_1, A_2)$ over $E_i \to (X_i, g_i)$ for $i = 1, 2$. This implies that when one stretches the neck of the connected sum so that the connected sum part is isometric to $[-T, T] \times S^3$ for large $T \gg 1$, then $E$ splits as $E \cong E_1 \# E_2$ with $SU(2)$ bundles $E_i \to X_i$.

Suppose $\dim M(E, g_a) = 0$ is zero. Then the additive formula

$$\dim M(E) = \dim M(E_1) + \dim M(E_2) + 3$$

shows that $\dim M(E_i, g^i) < 0$ is negative for $i = 1$ or $i = 2$, and hence it is generically empty, which is a contradiction to the fact that $[A_i] \in M(E_i)$. Here $\dim M(E_i)$ is the formal dimension. See Section 7.2.5 of [14] for the additive formula. When $\dim M(E, g_a) > 0$ is positive, then the dual submanifold of the image of $\mu$ map satisfy the same phenomena.

This leads to vanishing of the invariant. \( \text{q.e.d.} \)

Let us try to follow a parallel argument for the twisted Donaldson invariants. However it turns out that the free product of groups behaves rather differently from direct product. For example it is well known that

$$K_0(C_r^*(F_n)) = K_0(C_r^*(F_{n-1} \ast Z)) \cong \cdots \cong Z.$$ 

So the Mischenko bundle $\gamma = X \times_{\Gamma} C_r^*(\Gamma)$ will not split as the sum of $\gamma_i = X \times_{\Gamma_i} C_r^*(\Gamma_i)$, and the twisted $\mu$ map cannot split as the standard $\mu$ map, and hence the parallel argument breaks.

1.1.2. **Cohomological formula.** However as we will see below, if we pass through more cohomological argument in non commutative geometry, then we can verify vanishing of the twisted Donaldson invariants for groups which posses some characteristics. It turn out that such characteristics touches with validity of the Novikov conjecture on homotopy invariance of higher signatures.

**Lemma 1.6.** Let $\Gamma$ be admissible and $HP^*(C^\infty(\Gamma))$ is finite dimensional. Then the twisted Donaldson invariants vanish $\Psi^{(r)}_{X, f} \equiv 0$, if $X = X_1 \sharp X_2$ splits as a connected sum with $b^+(X_i) \geq 1$.

This is verified by using the cohomological formula on the twisted $\mu$ map, when the group is admissible.
In theorem 5.6, we have verified a cohomology formula
\[
\langle [\eta] \otimes [\xi] \otimes [C], \mu^w_{\text{tw}}(\alpha, \beta) \rangle = \langle \text{ch}(\hat{E}) \wedge f^*\eta, [M \times C] \rangle \langle \hat{A}(N) \wedge j^*\xi, [N] \rangle \in \mathbb{C}
\]
Hence our twisted Donaldson invariant is described by the classical Donaldson invariant, when \( \Gamma \) is admissible and \( H^P(\mathcal{C}^\infty(\Gamma)) \) is finite dimensional. In particular it verifies our conjecture in this case. On the other hand Connes-Moscovici has verified the Novikov conjecture for admissible groups (see proposition 1.3). The Novikov conjecture is still open in general and is a fundamental problem in the study of high dimensional smooth structure. Hence the admissibility condition consists of an important class of discrete groups, but assumes a strong constrain on structure of groups.

Our main theme in this paper is to construct a bridge between Yang-Mills theory and non commutative geometry. What we made non commutative was the cohomology classes over the standard ASD moduli space. We did not use non commutative ASD moduli space which consists of gauge equivalent classes of ASD connections over \( E \otimes (\tilde{X} \times_{\Gamma} \mathcal{C}^*_r(\Gamma)) \). Its analysis seems quite hard, since it is infinite dimensional. On the other hand, a non commutative action functional in non commutative geometry was already introduced by Connes [8]. As a next step in future work, we shall study non commutative ASD moduli space based on our approach combined with Connes action functional. We hope very much it will lead to a construction of ‘non commutative Donaldson invariant’.

We also include basics materials of Yang-Mills gauge theory in section 2 and non commutative geometry in section 4, for the convenience of readers in different fields.

2. Review of Yang-Mills Gauge Theory

2.1. Donaldson invariant. Let \((X, g)\) be an oriented, closed, smooth Riemannian four-manifold. Take an \(SU(2)\) vector bundle \( E \to X \), and \( g = P \times SU(2) \mathfrak{su}(2) \) be the adjoint bundle, where \( P \) is the principal \( SU(2)\)-bundle associated with \( E \).

We denote by \( \mathfrak{A}(E) \) the space of connections on \( E \), which is an affine space of sections on the cotangent bundle twisted by the adjoint bundle. So if we choose a base connection \( A_0 \) on \( E \), then we can write it as:
\[
\mathfrak{A}(E) = A_0 + \Gamma(X; \Lambda^1 \otimes \mathfrak{g}).
\]
The gauge group \( \mathfrak{G}(E) \) acts on \( \mathfrak{A}(E) \) by conjugation \( g^*(A_0 + a) \equiv g^{-1} \circ (A_0 + a) \circ g \).

The action of the subgroup \( \{\pm 1\} \) of \( \mathfrak{G}(E) \) is trivial. Hence we have the action of \( \mathfrak{G}(E)/\{\pm 1\} \) on \( \mathfrak{A}(E) \). It is a basic matter that \( \mathfrak{G}(E)/\{\pm 1\} \) acts on the set of irreducible connections \( \mathfrak{A}^*(E) \subset \mathfrak{A}(E) \) freely, and hence the quotient space:
\[
\mathfrak{B}^*(E) = \mathfrak{A}^*(E)/\mathfrak{G}(E) = \mathfrak{A}^*(E)/(\mathfrak{G}(E)/\{\pm\})
\]
becomes a regular Hilbert manifold under taking completion by a Sobolev norm.

The Hodge $\ast$ operator acts on two forms into themselves as: $\ast : \wedge^2 V \to \wedge^2 V$ with $\ast^2 = 1$, if $V$ is a 4-dimensional Euclidean space. So $\wedge^2 V$ splits into self-dual and anti self-dual vectors $\wedge^2 V = (\wedge^2 V)^+ \oplus (\wedge^2 V)^-$. Let:

$$F^+ : \mathfrak{A}(E) \to \Gamma(X; g \otimes \wedge^+)$$

be the self-dual part of the curvature, which is given by the orthogonal projection of the curvature $F$. Let us consider the space of anti self-dual connections:

$$\mathfrak{M}(E, g) = \{ A \in \mathfrak{A}(E); \; F^+(A) = 0 \} \subset \mathfrak{A}(E).$$

The gauge group $\mathfrak{G}(E)$ acts on $\mathfrak{M}(E, g)$.

**Definition 2.1.** The moduli space of anti self-dual (ASD) connections is given by the quotient:

$$\mathfrak{M}(E, g) = \mathfrak{M}(E, g) / \mathfrak{G}(E).$$

It follows from the Atiyah-Singer index theorem that the formal dimension of the moduli space is given by:

$$8c_2(E) + \frac{3}{2}(\chi(X) - \tau(X)) = 8c_2(E) - 3(1 - b_1(X) + b^+(X))$$

where $\chi(X)$ is the Euler characteristic and $\tau(X)$ is the signature of $X$ respectively.

It follows from transversality argument that for a generic metric $g$, the moduli space $\mathfrak{M}(E, g)$ is smooth if $b^+(X) > 1$ and $c_2(E) > 0$. Hence we have the inclusion:

$$\mathfrak{M}(E, g) \subset \mathfrak{B}^*(E).$$

In general this does not give a homology class in $H_*(\mathfrak{B}^*(E); \mathbb{Z})$, since the moduli space is non compact.

Let us describe roughly how to formulate the Donaldson invariant. Let $\mathfrak{G}^0(E)$ be the framed gauge group:

$$\mathfrak{G}^0(E) := \{ u \in \mathfrak{G}(E); \; u(x_0) = 1 \}$$

where $x_0$ is a fixed point in $X$. Put:

$$\mathfrak{B}(E) := \mathfrak{A}(E) / \mathfrak{G}^0(E)$$

and consider a vector bundle $\tilde{E}$ on $X \times \mathfrak{B}(E)$ defined by the following:

$$\tilde{E} := E \times_{\mathfrak{G}^0(E)} \mathfrak{A}(E).$$

It is well known that the adjoint bundle $\mathfrak{g}_{\tilde{E}}$ of $\tilde{E}$ descends to a vector bundle $\mathfrak{g}_{\tilde{E}}$ over $X \times \mathfrak{B}^*(E)$, while the vector bundle $\tilde{E}$ itself does not descend to a vector bundle over $X \times \mathfrak{B}^*(E)$ in general.

We define:

$$\mu : H_*(X; \mathbb{Z}) \to H^{1-*}(\mathfrak{B}^*(E); \mathbb{Q}),$$

$$\mu(\alpha) := -\frac{1}{4} p_1(\mathfrak{g}_{\tilde{E}}) / \alpha.$$
A choice of an orientation $O$ of the vector space $\mathcal{H}_1(X) \oplus \mathcal{H}^+(X)$ gives an orientation on the moduli space, where $\mathcal{H}_1(X)$ and $\mathcal{H}^+(X)$ are the spaces of harmonic 1-forms and self-dual harmonic two forms respectively. See [11]. Let $A(X)$ be as in (1.2). Then the Donaldson invariant is a linear map:

$$\Psi_X : A(X) \to \mathbb{Q}$$

which depends on the orientation $O$ up to sign, but usually we drop it from our notation. Roughly speaking, the Donaldson invariant is given by the integral formula:

$$\Psi_X(\alpha_1, \ldots, \alpha_d) = \int_{\mathcal{M}(E, g)} \mu(\alpha_1) \cup \cdots \cup \mu(\alpha_d)$$

if there is an $SU(2)$ vector bundle $E$ with:

$$\dim \mathcal{M}(E, g) = \deg \{ \mu(\alpha_1) \cup \cdots \cup \mu(\alpha_d) \}.$$

Otherwise we put $\Psi_X(\alpha_1, \ldots, \alpha_d) = 0$.

In order for the above formula to make sense, the cohomology classes $\mu(\alpha_j)$ should have compact support, since $\mathcal{M}(E, g)$ is not compact in general. To overcome this difficulty, we pass through dual submanifolds of $\mu(\alpha_j)$, which behave nicely near the end of the moduli space. Later we will describe such construction.

Technically speaking, reducible $SU(2)$-flat connections affect to find such dual submanifolds. To avoid such connections, we take the blow-up:

$$(2.1) \quad \hat{X} = X \# \mathbb{CP}^2$$

and choose the $U(2)$-vector bundle $\hat{E}$ on $\hat{X}$ with:

$$\quad c_1(\hat{E}) = e \quad \text{and} \quad c_2(\hat{E}) = c_2(E).$$

Here $e$ is the standard generator of $H^2(\mathbb{CP}^2; \mathbb{Z}) \subset H^2(\hat{X}; \mathbb{Z})$. See remark 2.2 below. This technique was introduced in [30]. See also [23] and section 6.3 of [12].

Fix a connection $a_0$ on $\det \hat{E}$. We will always consider connections on $\hat{E}$ compatible with $a_0$ so that their determinants coincide with $a_0$. The moduli spaces should be denoted as $\mathcal{M}(\hat{E}, \hat{g}, a_0)$ apriori. But the invariants defined here are actually all independent of $a_0$. So we omit to denote $a_0$ and write it as $\mathcal{M}(\hat{E}, \hat{g})$.

**Remark 2.2.** Take two connections $a_0, a_1$ on $\det \hat{E}$. For $t \in [0, 1]$, put $a_t = (1-t)a_0 + ta_1$. Then it gives a family of the moduli spaces parametrized by $t$, and the family forms a cobordism between $\mathcal{M}(\hat{E}, \hat{g}, a_0)$ and $\mathcal{M}(\hat{E}, \hat{g}, a_1)$. This cobordism is diffeomorphic to the trivial cobordism, and the invariants are independent of choice of $a_0$.

If $c_2(\hat{E}) > 0$, for a generic metric $\hat{g}$, the moduli space $\mathcal{M}(\hat{E}, \hat{g})$ of ASD connections on $\hat{E}$ is smooth and included in $\mathcal{B}^+(\hat{E})$. Moreover we have the dimension formula:

$$\quad (2.3) \quad \dim \mathcal{M}(\hat{E}, \hat{g}) = \dim \mathcal{M}(E, g) + 2.$$
an integral homology class \( \alpha = [M] \in H_*(X; \mathbb{Z}) \) for \(* \leq 3\), where \( M \) is a submanifold in \( X \). Consider a suitable neighborhood \( U \) of \( M \) in \( X \) in the sense of \([23, p.589]\). We may think of \( U \) as a subset in \( X \). Let \( \mathfrak{B}_U^* \) be the configuration space of irreducible connections on \( \hat{E} \mid_U = E \mid_U \). Since the restriction of an irreducible ASD connection over \( \hat{X} \) to the open subset \( U \) is still irreducible, we have the restriction map:

\[
r_U : \mathfrak{M}(\hat{E}, \hat{g}) \rightarrow \mathfrak{B}_U^*.
\]

For any subset \( B \subset \mathfrak{B}_U^* \), we put:

\[
\mathfrak{M}(\hat{E}, \hat{g}) \cap B := \{ [A] \in \mathfrak{M}(\hat{E}, \hat{g}); \ r_U([A]) \in B \}.
\]

We will construct a generic submanifold \( V_M \) in \( \mathfrak{B}_U^* \) of codimension \( 4 - * \) such that:

\[
\mathfrak{M}(\hat{E}, \hat{g}) \cap V_M
\]

is transverse and is a submanifold in \( \mathfrak{B}_U^* \) dual to \( \mu([M]) \). This behaves nicely near the end of the moduli space.

Let us present how to construct \( V_M \) for \( \alpha = [M] \in H_*(X; \mathbb{Z}) \) for \(* \leq 3\).

2.2. Dual submanifolds of \( \mu(\alpha) \).

2.2.1. The case \( \deg \alpha = 0 \). We consider the degree 0 case. Let \( x \) be a point in \( X \). Take a suitable neighborhood \( \nu(x) \) of \( x \). Let \( g_{x, \mathbb{C}} \) be the complexification of the vector bundle

\[
g_x := \tilde{\mathfrak{B}}_{\nu(x)}^* \times_{\text{ad}} \mathfrak{su}(2)
\]

over \( \mathfrak{B}_{\nu(x)}^* \) with fiber \( \mathfrak{su}(2) \). Take generic section \( s_1 \) and \( s_2 \) of \( g_{x, \mathbb{C}} \). Let \( V_x \) in \( \mathfrak{B}_{\nu(x)}^* \) be the locus where \( s_1 \) and \( s_2 \) are not linear independent. Then \( V_x \) is a codimension-4 stratified subset in \( \mathfrak{B}_{\nu(x)}^* \), which is dual to \( 4\mu([x]) \).

Remark 2.3. The subspace \( V_x \) is dual to \( 4\mu([x]) \) rather than \( \mu([x]) \). Because of this fact, we will have the factor \( \frac{1}{4} \) in the definition of the Donaldson invariant in definition 2.7.

2.2.2. The case \( \deg \alpha = 1 \). Take a homology class \([\ell] \in H_1(X; \mathbb{Z})\), where \( \ell \) is a loop in \( X \). We may regard \( \ell \) as a loop in \( \hat{X} \). Fix a neighborhood \( \nu(\ell) \) of \( \ell \) in \( \hat{X} \) which is suitable in the sense of \([23, p.589]\). For each connection \( A \) on \( E_{|\nu(\ell)} (= \hat{E}_{|\nu(\ell)}) \) consider its holonomy \( h_\ell(A) \in SU(2) \) along \( \ell \). The holonomy assignment gives a section \( h_\ell : \mathfrak{B}_{\nu(\ell)}^* \rightarrow \text{ad} \tilde{\mathfrak{B}}_{\nu(\ell)}^* = \tilde{\mathfrak{B}}_{\nu(\ell)}^* \times_{\text{ad}} SU(2) \). If we perturb \( h_\ell \) slightly, then we get a section \( h'_\ell \) of \( \text{ad} \tilde{\mathfrak{B}}_{\nu(\ell)}^* \) such that \( h'_\ell \) is transverse to the trivial section \( s_0 \) of \( \text{ad} \tilde{\mathfrak{B}}_{\nu(\ell)}^* \) defined by \( s_0([A]) = [A, 1] \). Put:

\[
V_\ell := (h'_\ell)^{-1}(1).
\]

Here 1 stands for the image of \( s_0 \). Then \( V_\ell \) is a submanifold in \( \mathfrak{B}_{\nu(\ell)}^* \) of codimension 3.
2.2.3. The case $\deg \alpha = 2$. Take $\alpha \in H_2(X; \mathbb{Z})$, and let $\Sigma \subset X$ be an embedded, closed and oriented surface representing $\alpha$. Consider the restriction $E|_\Sigma \to \Sigma$, and let $\mathcal{B}_\Sigma = \mathcal{A}_\Sigma / G_0^\Sigma$ be the configuration space of framed connections on $E|_\Sigma (= E|_\Sigma)$, with the framed gauge group $G_0^\Sigma = \{ g \in \mathfrak{g}_{\Sigma} | g(x_0) = 1 \}$ over $\Sigma$ for a fixed point $x_0 \in \Sigma$. We have the universal $SU(2)$-vector bundle:

$$\tilde{\mathcal{E}}_\Sigma = (E|_\Sigma) \times_{\mathfrak{g}_{\Sigma}} \mathcal{A}_\Sigma \to \Sigma \times \tilde{\mathcal{B}}_\Sigma$$

which presents the universal family of bundles with connections on $\Sigma$.

Fix a spin structure on $\Sigma$, and let $D^\Sigma$ be the Dirac operator over $\Sigma$ as the twisted $\bar{\partial}$ operator. Each $SU(2)$ connection $A$ gives the associated Dirac operator $D_A$, and hence such assignment induces the universal family of the Dirac operators over the configuration space $\tilde{\mathcal{B}}_\Sigma$.

Let $\mathcal{L}_\Sigma \to \mathcal{B}_\Sigma$ be the determinant line bundle of the family of the Dirac operators. We write $\mathcal{B}(\hat{E})$ and $\mathcal{B}^*(\hat{E})$ for the configuration spaces of framed connections and irreducible connections over $\hat{E}$ compatible with the fixed connection $a_0$. It is known that the pull-back $r^*_\Sigma \tilde{\mathcal{L}}_\Sigma$ descends to a line bundle:

$$\mathcal{L}_\Sigma \to \mathcal{B}^*(\hat{E})$$

where $r^*_\Sigma : \tilde{\mathcal{B}}(\hat{E}) \to \tilde{\mathcal{B}}_\Sigma$ is the restriction map. The Atiyah-Singer index theorem for family computes the following:

**Proposition 2.4.** $\mu(\Sigma) = c_1(\mathcal{L}_\Sigma) \in H^2(\mathcal{B}^*(\hat{E}); \mathbb{Q})$.

Take a neighborhood $\nu(\Sigma) \subset X$ of $\Sigma$ which is suitable in the sense of [23, p.589]. As above $\mathcal{L}_\Sigma$ naturally induces a line bundle $\mathcal{L}_{\nu(\Sigma)} \to \mathcal{B}^*(\nu(\Sigma))$. Then the submanifold $V_\Sigma$ is given by the zero set of $s^\Sigma$:

$$V_\Sigma := s^{-1}_{\nu(\Sigma)}(0)$$

for any generic section $s_{\nu(\Sigma)} : \mathcal{B}^*(\nu(\Sigma)) \to \mathcal{L}_{\nu(\Sigma)}$.

**Remark 2.5.** Notice that the first Chern class of the determinant line bundle is the same as the one of the family of the index bundle. A merit to use the determinant line bundle is that its Poincaré dual class is expressed by the pull back of a generic section of $\mathcal{L}_\Sigma$. This is technically important since the moduli space is non compact in general.

2.2.4. The case $\deg \alpha = 3$. Take $\alpha = [M] \in H_3(X; \mathbb{Z})$ represented by an closed, oriented 3-manifold $M$ embedded in $X$. Take a suitable neighborhood $\nu(M)$. We have the Chern-Simons functional

$$CS_M : \mathcal{B}^*(\nu(M)) \to S^1 = \mathbb{R}/\mathbb{Z}.$$  

We may suppose that $0 \in S^1$ is a regular value of $CS_M$ after perturbing $CS_M$ slightly. The submanifold is given by

$$V_M := CS^{-1}_M(0).$$

2.3. Homology and bordism classes of the intersection of submanifolds $V_M$. 
2.3.1. **Main statement.** Take homology classes \([M_1], \ldots, [M_d] \in H_{\leq 3}(X; \mathbb{Z})\) and their neighborhoods \(\nu(M_i) \subset X\) of \(M_i\), which is suitable in the sense of [23] p.589. (If \([M_j] \in H_0(X; \mathbb{Z})\), then we assume that \([M_j]\) is the generator \([pt]\) of \(H_0(X; \mathbb{Z})\) which is represented by a single point \(pt\) of \(X\).) We may suppose that

\[(2.4) \quad \nu(M_{i_1}) \cap \cdots \cap \nu(M_{i_p}) = \emptyset\]

for \(\{i_1, \ldots, i_p\} \subset \{1, \ldots, d\}\) with

\[(4 - \dim M_{i_1}) + \cdots + (4 - \dim M_{i_p}) > 4.\]

**Proposition 2.6.** Suppose \(b^+(X) > 1\), and the inequality

\[
\dim \mathfrak{M}(\hat{E}, \hat{g}) = \sum_{j=1}^{d} (4 - \dim M_j) + r
\]

holds for some \(r \in \{0, 1, 2, 3\}\). Then the intersection:

\[(2.5) \quad V(\hat{E}, \hat{g}; M_1, \ldots, M_d) := \mathfrak{M}(\hat{E}, \hat{g}) \cap V_{M_1} \cap \cdots \cap V_{M_d}\]

is a compact, smooth submanifold in \(\mathfrak{M}(\hat{E}, \hat{g})\) of dimension \(r\).

The orientation \(O\) of \(\mathcal{H}^1(X) \oplus \mathcal{H}^+(X)\) induces an orientation of the intersection. If \(r \leq 2\), the homology class:

\([V(\hat{E}, \hat{g}; M_1, \ldots, M_d)] \in H_
u(\mathfrak{B}^*(\hat{E}); \mathbb{Z})\]

and the oriented bordism class:

\([V(\hat{E}, \hat{g}; M_1, \ldots, M_d)] \in \Omega^S(\mathfrak{B}^*(\hat{E}))\)

are both independent of choice of \(\hat{g}\) and \(V_{M_i}\). It depends only on \(\hat{E}\), the homotopy classes \([M_j: S^1 \to X] \in \pi_1(X)\) with \(\dim M_j = 1\) and the homology classes \([M_j] \in H_*(X; \mathbb{Z})\) with \(\dim M_j = 0, 2\) or \(3\).

2.3.2. **Compactness of \(V(\hat{E}, \hat{g}; M_1, \ldots, M_d)\).** We will prove the compactness of the space \(V(\hat{E}, \hat{g}; M_1, \ldots, M_d)\) in Proposition 2.6. It follows from a standard argument that \(V(\hat{E}', \hat{g}; M_{i_1}, \ldots, M_{i_p})\) are smooth manifolds of the expected dimension for a generic metric \(\hat{g}\) on \(\hat{X}\), generic representatives \(V_{M_i}\) and \(\{i_1, \ldots, i_p\} \subset \{1, \ldots, d\}\). Here \(\hat{E}'\) is any \(U(2)\) vector bundle with \(0 \leq c_2(\hat{E}') \leq c_2(\hat{E})\) and \(c_1(\hat{E}') = e \in H^2(\hat{X}; \mathbb{Z})\). In particular, the negativity of the dimension:

\[
\dim V(\hat{E}'; M_{i_1}, \ldots, M_{i_p}) = \dim \mathfrak{M}(\hat{E}') - \sum_{k=1}^{p} (4 - \dim M_{i_k}) < 0
\]

implies that

\[
V(\hat{E}'; M_{i_1}, \ldots, M_{i_p}) = \emptyset.
\]

To verify that \(V(\hat{E}, \hat{g}; M_1, \ldots, M_d)\) is compact, take a sequence \([A_n]\) in \(V(\hat{E}, \hat{g}; M_1, \ldots, M_d)\). After passing to a subsequence, it converges as

\([A_n] \to ([A], x_1, \ldots, x_m) \in \mathfrak{M}(\hat{E}') \times \mathrm{Sym}^m X\)

where \(\hat{E}'\) is a \(U(2)\)-vector bundle with \(c_2(\hat{E}') = c_2(\hat{E}) - m\) and \(c_1(\hat{E}') = e\) for some \(0 \leq m \leq c_2(\hat{E})\), and \(x_i\) are the blowing up points.
We have to show $m = 0$. For each $x_j$, let $M_{i(j, 1)}, \ldots, M_{i(j, p(j))}$ be the submanifolds with $x_j \in \nu(M_{i(j, k)})$ for $k = 1, \ldots, p(j)$. Then we have the bounds:
\[
(4 - \dim M_{i(j, 1)}) + \cdots + (4 - \dim M_{i(j, p(j))}) \leq 4
\]
since \[2.4\] and
\[
x_j \in \nu(M_{i(j, 1)}) \cap \cdots \cap \nu(M_{i(j, p(j))}).
\]
Let $M_1, \ldots, M_q$ be the submanifolds which do not contain any of $x_j$. Then we have:
\[
[A] \in V(\hat{E}'; M_1, \ldots, M_q).
\]
On the other hand, the following estimates hold:
\[
\dim V(\hat{E}'; M_1, \ldots, M_q) \leq \dim V(\hat{E}; M_1, \ldots, M_d) - 8m
\]
\[
\quad + \sum_{j=1}^{m} \left\{ (4 - \dim M_{i(j, 1)}) + \cdots + (4 - \dim M_{i(j, p(j))}) \right\}
\]
\[
\quad \leq \dim V(\hat{E}; M_1, \ldots, M_d) - 4m
\]
\[
= r - 4m.
\]
So if $m > 0$ could be positive, then $\dim V(\hat{E}'; M_1, \ldots, M_q) < 0$ is negative, and hence $V(\hat{E}'; M_1, \ldots, M_q)$ must be empty. This is a contradiction since $[A] \in V(\hat{E}'; M_1, \ldots, M_q)$. Thus $m = 0$ and $V(\hat{E}; M_1, \ldots, M_d)$ is compact.

### 2.3.3. Invariance under change of metric
We will check that the classes of $V(\hat{E}; M_1, \ldots, M_d)$ in both $H_r(\mathfrak{B}^*(\hat{E}); \mathbb{Z})$ and $\Omega^{SO}_r(\mathfrak{B}^*(\hat{E}))$ are independent of choice of metrics $\hat{g}$ as follows. Take another metric $\hat{g}'$ and a generic path $G = \{\hat{g}_t\}_{0 \leq t \leq 1}$ from $\hat{g}$ to $\hat{g}'$. This gives a parametrized moduli spaces $\mathfrak{M}(\hat{E}, G)$. Then we obtain a cobordism $V(\hat{E}, G; M_1, \ldots, M_d)$ between the boundary components associated with the moduli spaces with respect to $\hat{g}$ and $\hat{g}'$, if we verify that it is compact.

We follow a parallel argument as above. Take $[A_i] \in V(\hat{E}, G; M_1, \ldots, M_d)$. Then they converge $[A_i] \to ([A], x_1, \ldots, x_m)$ after passing to a subsequence, and obtain an element $[A] \in V(\hat{E}', G; M_1, \ldots, M_q)$. Then the dimension estimate:
\[
\dim V(\hat{E}', G; M_1, \ldots, M_q) \leq r + 1 - 4m
\]
still implies that $m$ cannot be positive for $r = 0, 1, 2$.

### 2.3.4. Invariance under change of representatives $V_M$: The case $\dim M = 0$

The classes $[V(\hat{E}, \hat{g}; M_1, \ldots, M_d)]$ are also independent of the choice of the representatives $V_M$. We are left to prove that the classes $\{[V(\hat{E}; M_1, \ldots, M_d)] \in H_r(\mathfrak{B}^*(\hat{E}); \mathbb{Z}), [V(\hat{E}; M_1, \ldots, M_d)] \in \Omega^{SO}_r(\mathfrak{B}^*(\hat{E}))\}$ depend only on the homotopy class $[M_j : S^1 \to X] \in \pi_1(X)$ with $\dim M_j = 1$ and homology class $[M_j] \in H_*(X; \mathbb{Z})$ with $\dim M_j = 0, 1$ or 3.

First we will consider the case $\dim M_1 = 0$. That is $M_1$ is a point $x$ of $X$. As in Section 2.2.4 choose pairs of generic sections $(s_1, s_2)$, $(s'_1, s'_2)$ of the bundle $\mathfrak{g}_x \otimes \mathbb{C}, \mathfrak{g}_{x'} \otimes \mathbb{C}$ over $B^*_V(x), B^*_{V(x')}$. Then we get two representatives
We define a homotopy of sections

\[ \nu(x), \ \nu(x') \subset \nu(\gamma). \]

We have the adjoint bundle \( g_{\nu(\gamma)} \otimes \mathbb{C} \) over \( B_{\nu(\gamma)}^* \). Put

\[ B_{\nu(\gamma)}^{**} := \{ [A] \in B_{\nu(\gamma)} \} \]

Both \( r_{\nu(x)}(A) \) and \( r_{\nu(x')}(A) \) are irreducible.

Here \( r_{\nu(x)}, r_{\nu(x')} \) are the restrictions. Take pair of generic sections \((t_1, t_2)\) of the bundle \((g_{\nu(\gamma)} \otimes \mathbb{C}) \times [0, 1] \) over \( B_{\nu(\gamma)}^{**} \times [0, 1] \) such that

\[ t_1|_{B_{\nu(\gamma)}^{**} \times \{0\}} = r_{\nu(x)}^{*} s_1, \quad t_1|_{B_{\nu(\gamma)}^{**} \times \{1\}} = r_{\nu(x')}^{*} s'_1. \]

Let \( V(t_1, t_2) \) be the locus where \( t_1, t_2 \) are not linear independent. Then we can show that

\[ \{ V(\hat{E}, \hat{g}; M_2, \ldots, M_d) \times [0, 1] \} \cap V(t_1, t_2) \]

is a bordism between

\[ V(\hat{E}, \hat{g}; M_2, \ldots, M_d) \cap V_{M_i} \]

and

\[ V(\hat{E}, \hat{g}; M_2, \ldots, M_d) \cap V'_{M_i}. \]

2.3.5. Invariance under change of representatives \( V_M \): The case \( \dim M = 1 \).

Suppose that \( M_1, N_1 : S^1 \rightarrow X \) are embeddings in \( X \) with \( M_1(0) = N_1(0) = x_0 \) and with

\[ [M_1] = [N_1] \quad \text{in} \quad \pi_1(X). \]

We can find a homotopy

\[ H : S^1 \times [0, 1] \rightarrow X \]

with \( H(0, t) = x_0 \) and with \( H(\cdot, 0) = M_1, H(\cdot, 1) = N_1 \). Put

\[ W := \{ H(s, t) | s \in S^1, t \in [0, 1] \} \subset X. \]

Choose a neighborhood \( \nu(W) \) of \( W \) in \( X \) with

\[ \nu(M_1), \ \nu(N_1) \subset \nu(W). \]

After perturbing \( H \), we may suppose that if

\[ \nu(W) \cap \nu(M_1) \cap \cdots \cap \nu(M_{i_p}) \neq \emptyset \]

then

\[ 2 + (4 - \dim M_{i_1}) + \cdots + (4 - \dim M_{i_p}) \leq 4 \]

for distinct \( i_1, \ldots, i_p \geq 2 \).

Put

\[ B_{\nu(W)}^{**} := \{ [A] \in B^*(E|_{\nu(W)}) \} \quad \text{[\( A|_{\nu(M_1)} \) and \( A|_{\nu(N_1)} \) are irreducible].} \]

We define a homotopy of sections

\[ H' : B_{\nu(W)}^{**} \times [0, 1] \rightarrow \text{ad} \ B_{\nu(W)}^{**} \]

of the adjoint bundle by

\[ H'([A], t) := h_t([A]), \]
where $h_t$ stands for the holonomy along the loop $H|_{S^1 \times \{t\}}$. We denote the preimage $(H')^{-1}(1)$ by $V_W$. We will prove that

\[(2.9) \quad \{V(\hat{E}; M_2, \ldots, M_d) \times [0, 1]\} \cap V_W\]

is compact and a bordism between $V(\hat{E}; M_1, M_2, \ldots, M_d)$ and $V(\hat{E}; N_1, M_2, \ldots, M_d)$. Perturbing the homotopy $H'$, we may suppose that the intersection (2.9) is transverse. To prove it is compact, take a sequence $([A_n], t_n)$ in the intersection (2.9). After passing to a subsequence,

\[[A_n] \to ([A_\infty], x_1, \ldots, x_m) \in \mathcal{M}(\hat{E}') \times \text{Sym}^m X, \ t_n \to t.\]

Suppose that $x_1, \ldots, x_m$ are all not in $\nu(W)$. Let $M_{i(j,1)}, \ldots, M_{i(j,p(j))}$ be the submanifolds with $x_j \in \nu(M_{i(j,k)})$ for $k = 1, \ldots, p(j)$. Then we have the inequality (2.6) for each $j$ and

\[([A], t) \in \{V(\hat{E}'; M_{i_1}, \ldots, M_{i_k}) \times [0, 1]\} \cap V_W.\]

Here $i_1, \ldots, i_q \geq 2$ and $M_{i_1}, \ldots, M_{i_q}$ are the submanifolds with $x_j \notin \nu(M_{i_k})$ for all $j$. As (2.7), we have

\[
\dim\{V(\hat{E}'; M_{i_1}, \ldots, M_{i_q}) \times [0, 1]\} \cap V_W \leq r + 1 - 4m.
\]

If $m \geq 1$, \(\dim\{V(\hat{E}'; M_{i_1}, \ldots, M_{i_q}) \times [0, 1]\} \cap V_W < 0\) and we obtain a contradiction. Thus $[A_n]$ must converge to a point in the intersection (2.9). Next suppose that $x_1 \in \nu(W)$. Then we have

\[[A] \in V(\hat{E}'; M_{i_1}, \ldots, M_{i_q}).\]

Here $i_1, \ldots, i_q \geq 2$ and $M_{i_1}, \ldots, M_{i_q}$ are the submanifolds with $x_j \notin \nu(M_{i_k})$ for all $j$. Let $M_{i(j,1)}, \ldots, M_{i(j,p(j))}$ be the submanifolds with $i(j,k) \geq 2$ and with $x_j \in \nu(M_{i(j,k)})$ for $k = 1, \ldots, p(j)$. By (2.9) and (2.8), we have

\[
\dim V(\hat{E}'; M_{i_1}, \ldots, M_{i_q})
\leq V(\hat{E}; M_1, \ldots, M_d) - 8m
+ 3 + (4 - \dim M_{i(1,1)}) + \cdots + (4 - \dim M_{i(p(1))})
+ \sum_{j=2}^{m}\{(4 - \dim M_{i(j,1)}) + \cdots + (4 - \dim M_{i(j,p(j))})\}
\leq r - 8m + 5 + 4(m - 1)
= r + 1 - 4m.
\]

Again, if $m \geq 1$, \(\dim V(\hat{E}'; M_{i_1}, \ldots, M_{i_q}) < 0\) and this is a contradiction. Therefore the intersection (2.9) is compact and a bordism between $V(M_1, M_2, \ldots, M_d)$ and $V(N_1, M_2, \ldots, M_d)$. So we have

\[\text{in } H_r(\mathfrak{B}^*(\hat{E}); \mathbb{Z}) \text{ and } \Omega^S_r(\mathfrak{B}^*(\hat{E})).\]
2.3.6. Invariance under change of representatives $V_M$: The case $\dim M = 2$. 
Next we will consider the case $\dim M_1 = 2$. Suppose that 
$$[M_1] = [N_1] \in H_2(X; \mathbb{Z}).$$ 
Recall that $V_{M_1}, V_{N_1}$ are the zero sets of sections 
$$s_{M_1} : \mathfrak{g}_{\nu(M_1)} \to \mathfrak{g}_{\nu(M_1)}, \quad s_{N_1} : \mathfrak{g}_{\nu(N_1)} \to \mathfrak{g}_{\nu(N_1)}.$$ 
There is the complex line bundle $L \to X$ with $c_1(L) = PD([M_1])$ and generic sections $s_0, s_1$ of $L$ such that 
$$s_0^{-1}(0) = M_1, \quad s_1^{-1}(0) = N_1.$$ 
Take a generic section 
$$H : X \times [0, 1] \to L$$ 
with 
$$H(\cdot, 0) = s_0, \quad H(\cdot, 1) = s_1.$$ 
Put 
$$W := H^{-1}(0) \subset X \times [0, 1].$$ 
Then $W$ is a submanifold in $X \times [0, 1]$ with $\partial W = M_1 \times \{0\} \bigsqcup N_1 \times \{1\}$. 
Choose a neighborhood $\nu(W)$ of $W$ in $X \times [0, 1]$ such that 
$$\nu(M_1) \times \{0\} \cup \nu(N_1) \times \{1\} \subset \nu(W).$$ 
First we will show that 
$$\pi_1(\mathfrak{B}_{\nu(W)}^{**}) = 1,$$ 
where $\mathfrak{B}_{\nu(W)}^{**}$ is the configuration space of connections $A$ on $\nu(W)$ such that $A|_{\nu(M_1) \times \{0\}}$ and $A|_{\nu(N_1) \times \{1\}}$ are irreducible. To see this, we consider the fibration 
$$\mathfrak{g}_{\nu(W)} \to \mathfrak{B}_{\nu(W)}^{**} \to \mathfrak{B}_{\nu(W)}^{**}.$$ 
Recall that $\nu(M_1)$ is a neighborhood of the sum of $M_1$ and loops in $X$. Similarly for $\nu(N_1)$. (See p. 589 of [23].) So we may suppose that $\nu(W)$ is a neighborhood of $W \cup l_1 \cup \cdots \cup l_q$, where $l_j$ is a loop. The homotopy exact sequence associated with the fibration shows that 
$$\pi_1(\mathfrak{B}_{\nu(W)}^{**}) \cong \pi_0(\mathfrak{g}_{\nu(W)})$$ 
$$= [\nu(W), SU(2)]$$ 
$$\cong [W \cup l_1 \cup \cdots \cup l_q, SU(2)]$$ 
$$= H^3(W \cup l_1 \cup \cdots \cup l_q; \mathbb{Z})$$ 
$$= 0.$$ 
We have used Corollary 16 of [34], Chapter 8, Section 1]. 
Let 
$$\mathbb{P}^{ad} \to \nu(W) \times \mathfrak{B}_{\nu(W)}^{**}$$ 
be the $SO(3)$-bundle defined as in p.176 of [14]. A calculation similar to that in Section 5.2 of [14] shows that 
$$c_1(r_0^* \mathcal{L}_{\nu(M_1)}) = -\frac{1}{4} p_1(\mathbb{P}^{ad})/[M_1] = -\frac{1}{4} p_1(\mathbb{P}^{ad})/[N_1] = c_1(r_1^* \mathcal{L}_{\nu(N_1)})$$
in $H^2(\mathfrak{B}^*_\nu(W); \mathbb{Q})$, where $r_0 : \mathfrak{B}^*_\nu(W) \to \mathfrak{B}^*_\nu(M_1)$, $r_1 : \mathfrak{B}^*_\nu(W) \to \mathfrak{B}^*_\nu(N_1)$ are the restriction maps $r_0([A]) = [A|_{\nu(M_1) \times \{0\}}]$, $r_1([A]) = [A|_{\nu(N_1) \times \{1\}}]$. As we have seen, $\pi_1(\mathfrak{B}^*_\nu(W)) = 1$ and hence $H^2(\mathfrak{B}^*_\nu(W); \mathbb{Z})$ is torsion free. Therefore

$$c_1(r_0^*\mathcal{L}_\nu(M_1)) = c_1(r_1^*\mathcal{L}_\nu(N_1))$$ in $H^2(\mathfrak{B}^*_\nu(W); \mathbb{Z})$, and $r_0^*\mathcal{L}_\nu(M_1)$ and $r_1^*\mathcal{L}_\nu(N_1)$ are isomorphic to each other. Fix an isomorphism $r_0^*\mathcal{L}_\nu(M_1) \cong r_1^*\mathcal{L}_\nu(N_1)$. Then we can take a generic section

$$H' : \mathfrak{B}^*_\nu(W) \times [0, 1] \to r_0^*\mathcal{L}_\nu(M_1)$$

with

$$H'(\cdot, 0) = r_0^*s_{M_1}, \quad H'(\cdot, 1) = r_1^*s_{N_1}.$$ Put $V_W := (H')^{-1}(0)$. The usual dimension counting argument shows that

$$(V(\hat{E}; M_2, \ldots, M_d) \times [0, 1]) \cap V_W$$ is compact and a bordism between $V(\hat{E}; M_1, M_2, \ldots, M_d)$ and $V(\hat{E}; N_1, M_2, \ldots, M_d)$.

2.3.7. Invariance under change of representatives $V_M$: The case $\dim M = 3$. We will consider the case $\dim M_1 = 3$. Suppose $[M_1] = [N_1]$ in $H_3(X; \mathbb{Z})$. We have smooth maps $f_0, f_1 : X \to S^1$ with $PD([M_1]) = [f_0] = [f_1]$ in $H^1(X; \mathbb{Z}) \cong [X, S^1]$ such that $0 \in S^1$ is a regular value of $f_0, f_1$ and $M_1 = f^{-1}(0), N_1 = f_1^{-1}(0)$. Since $[f_0] = [f_1]$ in $[X, S^1]$ we have a smooth map

$$H : X \times [0, 1] \to S^1$$

with $H(\cdot, 0) = f_0, H(\cdot, 1) = f_1$ such that $0 \in S^1$ is a regular value of $H$. Put

$$W = H^{-1}(0) \subset X \times [0, 1].$$

Then $W$ is a submanifold in $X \times [0, 1]$ with $\partial W = M_1 \times \{0\} \bigcup N_1 \times \{1\}$. We have the Chern-Simons functionals

$$CS_{M_1} : \mathfrak{B}^*_\nu(M_1) \to S^1, \quad CS_{N_1} : \mathfrak{B}^*_\nu(N_1) \to S^1,$$

$$\tilde{\mathfrak{B}}^*_\nu(W) \to \mathfrak{B}^*_\nu(M_1), \quad \tilde{\mathfrak{B}}^*_\nu(W) \to \mathfrak{B}^*_\nu(N_1).$$

Let $\tilde{r}_0 : \tilde{\mathfrak{B}}^*_\nu(W) \to \mathfrak{B}^*_\nu(W), \tilde{r}_1 : \tilde{\mathfrak{B}}^*_\nu(W) \to \mathfrak{B}^*_\nu(N_1)$ be the restriction maps and $\tilde{\mathcal{P}} \to \nu(W) \times \tilde{\mathfrak{B}}^*_\nu(W)$ be the universal $SU(2)$-bundle. We have

$$[\tilde{r}_0^*\tilde{CS}_{M_1}] = c_2(\tilde{\mathcal{P}})/[M_1] = c_2(\tilde{\mathcal{P}})/[N_1] = [\tilde{r}_0^*\tilde{CS}_{N_1}]$$

in $H^1(\tilde{\mathfrak{B}}^*_\nu(W); \mathbb{Z}) = [\tilde{\mathfrak{B}}^*_\nu(W), S^1]$. See p.178 of [14]. The homomorphism $H^1(\mathfrak{B}^*_\nu(W); \mathbb{Q}) \to H^1(\tilde{\mathfrak{B}}^*_\nu(W); \mathbb{Q})$ induced by the base point fibration is injective (see the proof of Proposition 5.1.15) and $H^1(\tilde{\mathfrak{B}}^*_\nu(W); \mathbb{Z})$ is torsion free by the universal coefficient theorem. These facts imply that

$$[r_0^*CS_{M_1}] = [r_1^*CS_{N_1}]$$

in $H^1(\mathfrak{B}^*_\nu(W); \mathbb{Z}) = [\mathfrak{B}^*_\nu(W), S^1]$. Therefore we have a homotopy

$$H' : \mathfrak{B}^*_\nu(W) \times [0, 1] \to S^1$$

with

$$H'(\cdot, 0) = r_0^*CS_{M_1}, \quad H'(\cdot, 1) = r_1^*CS_{N_1}.$$
We may suppose that $0 \in S^1$ is a regular value of $H'$. Put

$$V_W := (H')^{-1}(0).$$

Then we can show that

$$\{V(\hat{E}; M_2, \ldots, M_d) \times [0, 1] \cap V_W$$

is compact and a bordism between $V(\hat{E}; M_1, M_2, \ldots, M_d)$ and $V(\hat{E}; N_1, M_2, \ldots, M_d)$.

Take integral homology classes $[M_1], \ldots, [M_d] \in H_* (X; \mathbb{Z})$ for $* \leq 3$. If $[M_j] \in H_0 (X; \mathbb{Z})$, assume that $[M_j]$ is the generator of $H_0 (X; \mathbb{Z})$. If we have an $SU(2)$-bundle $E$ with:

$$r := \dim V(\hat{E}; M_1, \ldots, M_d) \leq 2,$$

then $V(\hat{E}; M_1, \ldots, M_d)$ defines the classes $[V(\hat{E}; M_1, \ldots, M_d)]$ in $H_r (\mathcal{B}^*(\hat{E}); \mathbb{Z})$ and $\Omega^*_{SO}(\mathcal{B}^*(\hat{E}))$ by proposition 2.6 which depends only on their homology classes $[M_j]$.

2.4. **Definition of $\Psi_X$.** We extend the definition of the class $[V(\hat{E}; M_1, \ldots, M_d)]$ to $H_0 (X; \mathbb{Z})$ linearly. For example, suppose that $[M_1] = n_1 [pt], \ldots, [M_d] = n_d [pt] \in H_0 (X; \mathbb{Z})$ where $[pt]$ is the generator of $H_0 (X; \mathbb{Z})$ and that $[M_{d_0+1}], \ldots, [M_d]$ are degree 1 or larger. Then we put

$$(2.10) \quad [V(\hat{E}; M_1, \ldots, M_d)] := n_1 \cdots n_d [V(\hat{E}; pt, \ldots, pt, M_{d_0+1}, \ldots, M_d)].$$

Note that if $E$ is an $SU(2)$ vector bundle with

$$\dim \mathfrak{M}(E) = \sum_{j=1}^d (4 - \dim M_j),$$

we have

$$[V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)] \in H_0 (\mathcal{B}^*(\hat{E}); \mathbb{Z}) \cong \mathbb{Z}$$

because of the formula $^{23}$). Here $[\Sigma_0]$ is the Poincare dual of the standard generator $e$ of $H^2 (\mathbb{CP}^2; \mathbb{Z})$.

**Definition 2.7.** We define the Donaldson invariant by:

$$\Psi_X ([M_1], \ldots, [M_d]) = \frac{1}{2} \cdot \frac{1}{4^{d_0} [V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)]} \in \mathbb{Q}$$

Here $d_0$ is the number of homology classes $[M_j]$ of degree 0. If there is no $SU(2)$ vector bundle $E$ with $\dim \mathfrak{M}(E) = \sum_{j=1}^d (4 - \dim M_j)$, then we define $\Psi_X ([M_1], \ldots, [M_d])$ to be 0.

**Remark 2.8.** The factor $\frac{1}{2}$ in the definition of $\Psi_X$ comes from the fact that $V_M$ is dual to $4^j (\mu ([M_j]))$ rather than $\mu ([M_j])$ if $[M_j] \in H_0 (X; \mathbb{Z})$. See remark $^{23}$.

The factor $\frac{1}{2}$ comes from the blow-up formula. In general the Donaldson invariant $\Psi_X$ can not be defined by a straightforward way, since reducible flat connections affect its construction. On the other hand when it is surely defined, we have the following formula:

$$\Psi_X ([M_1], \ldots, [M_d]) = \frac{1}{2} \Psi_X ([\Sigma_0], [M_1], \ldots, [M_d])$$
where $\hat{X}$ is the blow up of $X$. Even though the left hand side is not defined in general, the right hand side is always defined as we have described. So, it is natural to put $\Psi_X([M_1], \ldots, [M_d])$ to be the half of $\Psi_{\hat{X}}([\Sigma_0], [M_1], \ldots, [M_d])$.

We will make one more remark on the Donaldson invariant.

**Remark 2.9.** The Donaldson invariant $\Psi_X$ is a homomorphism. On $H_0(X; \mathbb{Z})$, it is easy to see that $\Psi_X$ is a homomorphism from (2.10). Suppose that $1 \leq \dim M_1 \leq 3$ and that there is an SU(2) vector bundle $E$ with $\dim \mathfrak{M}(E) = \sum_{j=1}^{d} (4 - \dim M_j)$. Note that

$$1 \leq \dim V(\hat{E}; \Sigma_0, M_1, \ldots, M_d) \leq 3.$$  

By proposition 2.6, $V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)$ is compact. Therefore we can write

$$\Psi_X([M_1], \ldots, [M_d]) = \frac{1}{2} \cdot \frac{4^{d-6}}{4^{d-6}} \left( \mu([M_1]), [V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)] \right).$$

Since $\mu$ is a homomorphism, $\Psi_X$ is a homomorphism on $H_*(X; \mathbb{Z})$ with $1 \leq * \leq 3$.

Recall that if $\dim M_j = 1$, the class $[V(\hat{E}; M_1, \ldots, M_d)]$ depends on the homotopy class $[M_j]$ in $\pi_1(X)$ rather than the homology class in $H_1(X; \mathbb{Z})$. (See proposition 2.6). Since the values of $\Psi_X$ are in $\mathbb{Q}$ which is commutative and $\Psi_X$ is a homomorphism, $\Psi_X$ descends to a map on $H_1(X; \mathbb{Z})$.

We have a natural sum decomposition:

$$\Psi_X = \sum_{k \in \mathbb{Z}_{>0}} \Psi_{X,k},$$

where $\Psi_{X,k} : A(X) \to \mathbb{Q}$ is defined by using the $U(2)$-vector bundle $\hat{E}$ with $c_2 = k$ and with $c_1 = e$:

$$\Psi_{X,k}([M_1], \ldots, [M_d]) = \begin{cases} \frac{1}{2} \cdot \frac{4^{d-6}}{4^{d-6}} [V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)] & \text{if } 8k - 3(1 - b_1(X) + b^+(X)) = \sum_{j=1}^{d} (4 - \dim M_j) \\ 0 & \text{otherwise.} \end{cases}$$

Then we put:

$$\Psi_{X,\text{odd}} := \sum_{k \in \mathbb{Z}_{>0}, k \equiv 1(2)} \Psi_{X,k}. \tag{2.11}$$

### 3. Twisted Donaldson Invariant for Commutative Case

A unitary representation of the fundamental group can be used to twist connections over a 4-manifold. In particular the characters of the Picard torus $\text{Pic}(B\pi_1(X))$ give rise to a family of moduli spaces fibered over the Picard torus when $\pi_1(X)$ is free abelian group $\Gamma = \mathbb{Z}^m$. More generally, we can consider a group homomorphism $f : \pi_1(X) \to \Gamma$, when $\pi_1(X)$ is not necessarily free abelian. By use of such structure, we introduce twisted Donaldson invariants

$$\Psi_{X,f}^{tw,r} : A(X) \otimes H_{\text{odd}}(X; \mathbb{Z}) \otimes H_1(B\Gamma; \mathbb{Z}) \to H^*(\text{Pic}(B\Gamma); \mathbb{Q})$$

for $r = 1, 2, 3, 4$. Here $A(X)$ is the domain of Donaldson invariants (1.2).
We verify that this version of the invariants are non trivial in the sense that they can be used to produce quite interesting properties on smooth structure on four manifolds. So this is a model case and motivates us to generalize our construction to the case of non commutative fundamental groups, by introducing a framework of non commutative geometry in section 5.

Throughout Section 3, we always assume that $X$ is a closed, spin and smooth 4-manifold with $b^+(X) > 1$. The reason why we need spin condition will be explained in subsection 3.1 below.

3.1. **Rank 1 case.** Put $\Gamma := \mathbb{Z}$ and take a homomorphism $f : \pi_1(X) \to \Gamma$. Below we introduce a twist of the $\mu$-map $\mu_{tw} : H_{odd}(X; \mathbb{Z}) \to \lim_{\leftarrow B} H^*(B \times \text{Pic}(B\Gamma); \mathbb{Q})$ using the family of flat connections, where $B$ runs over compact subsets in $\mathcal{B}^*(\hat{E})$.

We denote the Picard torus of $B\Gamma$ by $\text{Pic}(B\Gamma)$

$$\text{Pic}(B\Gamma) = H^1(B\Gamma; \mathbb{R})/H^1(B\Gamma; \mathbb{Z}) \cong S^1.$$  

Let us consider the universal line bundle $L \to B\Gamma \times \text{Pic}(B\Gamma)$ which consists of the family $\{L_\rho\}_{\rho \in \text{Pic}(B\Gamma)}$ of flat line bundles on $B\Gamma = S^1$ where $L_\rho := L|_{B\Gamma \times \{\rho\}}$ is the restriction. Its first Chern class is given by

$$c_1(L) = \omega \cup \eta \in H^1(B\Gamma; \mathbb{Z}) \otimes H^1(\text{Pic}(B\Gamma); \mathbb{Z}) = H^2(B\Gamma \times \text{Pic}(B\Gamma); \mathbb{Z}),$$

where $\omega \in H^1(B\Gamma; \mathbb{Z})$ and $\eta \in H^1(\text{Pic}(B\Gamma); \mathbb{Z})$ are the generators respectively.

Take an $SU(2)$-vector bundle $E$ on $X$ with $c_2(E)$ odd. To avoid difficulties caused by reducible flat connections, we use the $U(2)$-vector bundle $\hat{E}$ on the blow-up $\hat{X} = X \# \mathbb{C}P^2$ as in (2.1) with the conditions (2.2).

Let us describe the construction of the universal bundle $\tilde{\mathcal{E}} \to \hat{X} \times \mathcal{B}^*(\hat{E})$ of $\hat{E}$, following the discussion of Section 8.3.5 of [14]. Consider the bundle

$$\tilde{\mathcal{E}} := \hat{E} \times_{\mathfrak{A}(\hat{E})} \mathfrak{A}(\hat{E}) \to X \times \tilde{\mathcal{B}}(\hat{E})$$

where $\mathfrak{A}(\hat{E})$ is the space of $U(2)$-connections $A$ on $\hat{E}$ with a fixed determinant $\det A = a_0$. $\mathfrak{A}^0(\hat{E})$ is the gauge group on $\hat{E}$ whose elements $u$ satisfy $\det(u) = 1$ and $u(x_0) = 1$ for a fixed point $x_0$.

Let $\epsilon$ be the spin$^c$ structure on $\hat{X}$ with $c_1(\epsilon) = -e$. Coupling the spin$^c$ Dirac operator over $\hat{X}$ with $\tilde{\mathcal{E}}$, we obtain the family $\mathbb{D}_{\hat{X}}$ of the twisted spin$^c$ Dirac operators parametrized by $\tilde{\mathcal{B}}(\hat{E})$. We can take the real part of the operators $(\mathbb{D}_{\hat{X}})^R$ and obtain the real line bundle $\tilde{\Lambda} = \text{det Ind}(\mathbb{D}_{\hat{X}})^R$ on $\tilde{\mathcal{B}}(\hat{E})$. See Section 5 of [1].
Lemma 3.1. Suppose $X$ is spin and $c_2(\tilde{E})$ is odd. Then $\tilde{E} \otimes R \tilde{\Lambda}$ descends to a vector bundle
\[ \tilde{E} \to \tilde{X} \times B^*(\tilde{E}) \]

Proof. Note that the numerical index of the Dirac operators is odd. (See p.75 of [1].) This implies that $\tilde{E} \otimes R \tilde{\Lambda}$ descends to a vector bundle on $\tilde{X} \times B^*(\tilde{E})$ (see proposition 8.3.15 of [14]). q.e.d.

This is the point where we have to assume that $X$ is spin. (See also remark 3.10 below.) Later on we will always assume that all four manifolds are spin, otherwise stated.

The homomorphism $f : \pi_1(X) = \pi_1(\tilde{X}) \to \Gamma = \mathbb{Z}$ induces a continuous map
\[ \hat{f} : \tilde{X} \to B\Gamma \cong S^1 \]
which is unique up to homotopy. Let us introduce a twisted universal bundle
\[ \hat{E}_f^{tw} : = \tilde{E} \boxtimes_X (\hat{f} \times id)^* L \boxtimes_{Pic} L \to \tilde{X} \times B\Gamma \times B^*(\tilde{E}) \times Pic(B\Gamma) \]
as a family of vector bundles with connections on $\tilde{X} \times B\Gamma$ parametrized by $B^*(\tilde{E}) \times Pic(B\Gamma)$.

Firstly consider the fibered product
\[ \hat{E} \boxtimes_X (\hat{f} \times id)^* L \to \tilde{X} \times B^*(\tilde{E}) \times Pic(B\Gamma) \]
which is given by the family of twisted $U(2)$ bundles $(\tilde{E} \otimes L_{\rho}, [A_{\rho}])$ with twisted connections at $([A], \rho) \in B^*(\tilde{E}) \times Pic(B\Gamma)$.

Next let $(\hat{f} \times id)^* L \boxtimes_{Pic} L \to \tilde{X} \times B\Gamma \times Pic(B\Gamma)$ be the fibered product, which is given by the family of flat line bundles $\hat{f}^* L_{\rho} \boxtimes L_{\rho}$ at $\rho \in Pic(B\Gamma)$.

Then the twisted universal bundle is given by combination of these two constructions.

Take a homology class $[M] \in H_{odd}(X; \mathbb{Z})$ and realize it by a submanifold $M \subset X$. We may regard $M$ as a submanifold in $\tilde{X}$. The restriction
\[ \hat{E}_f^{tw} |_{M \times B\Gamma \times B^*(\tilde{E}) \times Pic(B\Gamma)} \]
gives a family of vector bundles with connections on $M \times B\Gamma$ parametrized by $B^*(\tilde{E}) \times Pic(B\Gamma)$.

$M \times B\Gamma$ admits a spin structure since $\dim M \leq 3$. So choose and fix it. Coupling the Dirac operator on $M \times B\Gamma$ with $\hat{E}_f^{tw} |_{M \times B\Gamma \times B^*(\tilde{E}) \times Pic(B\Gamma)}$, we get a family of the Dirac operators $\mathbb{D}_{M \times B\Gamma, f}$ parametrized by $B^*(\tilde{E}) \times Pic(B\Gamma)$.

Over a compact subset $B \subset B^*(\tilde{E})$, consider the index bundle of the family of the Dirac operators
\[ Ind_B \mathbb{D}_{M \times B\Gamma, f} \in K^*(B \times Pic(B\Gamma)). \]
It is compatible with the restriction in $K$ theory
\[ Ind_B \mathbb{D}_{M \times B\Gamma, f} = Ind_B' \mathbb{D}_{M \times B\Gamma, f} |_{B \times Pic(B\Gamma)} \]
for $B \subset B'$.
Definition 3.2. The twisted $\mu$-map $\mu_t^{tw}([M])$ is given by the collection
\[
\mu_t^{tw}([M]) \equiv \{ \ch(\text{Ind}_B \mathcal{D}_{M \times BG}) \}_B \in \lim_B H^*(B \times \text{Pic}(BG); \mathbb{Q}).
\]
Here $B$ runs over compact subsets in $\mathcal{B}^*(\hat{E})$.

We have the following.

Lemma 3.3. Under the above situation, the formula
\[
\mu_t^{tw}([M]) = \left\{ \begin{array}{cl}
\ch(\hat{E})/\alpha \cup \eta = -\mu(\alpha) \cup \eta + (\ch_{\geq 4}(\hat{E})/\alpha) \cup \eta \\
\end{array} \right.
\]
holds, where the right hand side is the image of $\ch(\hat{E})/[M \times BG]$ by the natural map
\[
H^*(\mathcal{B}^*(\hat{E}) \times \text{Pic}(BG); \mathbb{Q}) \to \lim_B H^*(B \times \text{Pic}(BG); \mathbb{Q}).
\]

In particular $\mu_t^{tw}([M])$ is independent of choices of representative $M$ of the homology class $[M] \in H_{odd}(X; \mathbb{Z})$ and spin structure on $M \times BG$.

Proof. For each compact subset $B \subset \mathcal{B}^*(\hat{E})$,
\[
\ch(\text{Ind}_B \mathcal{D}_{M \times BG}) = \left\{ \begin{array}{cl}
\ch(\hat{E})/\alpha \cup \eta \\
\end{array} \right.
\]
by the Atiyah-Singer index theorem for family. Here we have used the fact that $\hat{A}(M \times BG) = \hat{A}(M)\hat{A}(BG) = 1$ since $\dim M \leq 3$. q.e.d.

Remark 3.4. For $[M] \in H_{even}(X; \mathbb{Z})$, we can define $\mu^{tw}([M])$ as above. But $\mu_t^{tw}([M]) = 0$ since the dimension of $M \times BG$ is odd in this case.

Let us introduce the twisted Donaldson invariant below. To do this, we compute the following.

Recall that $\mu$ is the standard $\mu$ map in section 2.

Lemma 3.5. For $\alpha \in H_{odd}(X; \mathbb{Z})$, we have
\[
\mu_t^{tw}(\alpha) = (\ch(\hat{E})/\alpha) \cup \eta = -\mu(\alpha) \cup \eta + (\ch_{\geq 4}(\hat{E})/\alpha) \cup \eta
\]
where $\eta$ is the generator of $H^1(\text{Pic}(BG); \mathbb{Z})$.

In particular the following two cases happen:

(1)
\[
\mu_t^{tw}(\alpha)/c = 0
\]
if $\alpha \in H_{odd}(X; \mathbb{Z})$ and $c \in H_2(\mathcal{B}^*(\hat{E}); \mathbb{Z})$, or if $\alpha \in H_3(X; \mathbb{Z})$ and $c \in H_3(\mathcal{B}^*(\hat{E}); \mathbb{Z})$.

(2)
\[
\mu_t^{tw}(\alpha)/c = -\mu(\alpha)/c \cup \eta
\]
if $\alpha \in H_1(X; \mathbb{Z})$ and $c \in H_3(\mathcal{B}^*(\hat{E}); \mathbb{Z})$.

Proof. Take a homology class $\alpha = [M] \in H_{odd}(X; \mathbb{Z})$, and realize it by a submanifold $M \subset X$. Regard it as a submanifold in $\hat{X}$. By Lemma 3.3,
\[
\mu_t^{tw}(\alpha) = \ch(\hat{E})/[M \times BG]
\]
(3.1)
\[
= \ch(\hat{E}|_{M \times \mathcal{B}^*(\hat{E})}) \ch((\tilde{f} \times id)^*L) \ch(L)/[M \times BG]
\]
where $\tilde{f} : \tilde{X} \to B\Gamma$ is the continuous map. Let us verify
\begin{equation}
(3.2) \quad c_1(\tilde{E}|_{M \times \mathbb{B}^*(E)}) = 0.
\end{equation}
To see this, it is sufficient to check that $\tilde{E}|_{M \times \mathbb{B}^*(E)}$ has an $SU(2)$-vector bundle structure. Recall that $\tilde{E} \otimes_{\mathbb{R}} \tilde{A}$ descends to $\tilde{E}$ and the structure group of $\tilde{A}$ is $\{\pm 1\}$. Hence it is sufficient to verify that $\tilde{E}|_{M \times \mathbb{B}^*(E)}$ is an $SU(2)$-vector bundle. Let $P \to X$ be the $SU(2)$-principal bundle associated to $E$. Put a principal $SU(2)$-bundle
\[ \tilde{P}_M := (P|_M) \times_{\mathfrak{g}(E)} G(\tilde{E}) \to M \times \tilde{\mathbb{B}}(\tilde{E}). \]
Note that $\tilde{E}|_M = E|_M$, and hence the vector bundle associated to $\tilde{P}_M$ is $\tilde{E}|_{M \times \mathbb{B}^*(E)}$. So $\tilde{E}|_{M \times \mathbb{B}^*(E)}$ has an $SU(2)$-vector bundle structure.

We also have
\begin{equation}
(3.3) \quad c_1(L) = \omega \cup \eta, \quad c_1(L)^2 = 0, \quad c_3(\tilde{E}) = 0,
\end{equation}
where $\omega \in H^1(B\Gamma; \mathbb{Z})$, $\eta \in H^1(\text{Pic}(B\Gamma); \mathbb{Z})$ are the generators. Putting (3.2) and (3.3) together into (3.1), we obtain
\begin{align*}
\mu^t_w(\alpha) &= -(c_2(\tilde{E})/\alpha) \cup \eta + (\text{ch}_{\geq 4}(\tilde{E})/\alpha) \cup \eta \\
&= -\mu(\alpha) \cup \eta + (\text{ch}_{\geq 4}(\tilde{E})/\alpha) \cup \eta.
\end{align*}
Here we have used the equality $c_2(\tilde{E}) = -\frac{1}{4}p_1(\mathbb{B}_2)$. q.e.d.

Remark 3.6. The formula in Lemma 3.5 verifies that $\mu^t_w(\alpha)$ is actually independent of $f$. On the other hand $\mu^t_w(\alpha)$ does depend on $f$ in the higher rank case. See section 3.3 below.

3.1.1. Construction of $\Psi^{tw, (1)}_{X,f}$ and $\Psi^{tw, (2)}_{X,f}$. Take $[M_1], \ldots, [M_d] \in H_{\leq 3}(X; \mathbb{Z})$, where $M_j$ are submanifolds in $X$. Suppose that we have an $SU(2)$-vector bundle $E$ with $c_2(E)$ odd and with $\dim \mathfrak{M}(E) = \sum_{j=1}^{d}(4 - \dim M_j) + 1$. Let $\tilde{E}$ be the $U(2)$-vector bundle on $\tilde{X} = X \# \mathbb{CP}^2$ with conditions (2.2) and the relations on dimensions of moduli spaces (2.4).

Let $\Sigma_0$ be an embedded surface in $X$ with $[\Sigma_0] = PD(e)$ where $e \in H^2(\mathbb{CP}^2; \mathbb{Z})$ is the standard generator. Consider the situation in proposition 2.6 with $r = 1$, and so $V(\tilde{E}; \Sigma_0, M_1, \ldots, M_d)$ defines a homology class in $H_1(\mathbb{B}^4(\tilde{E}); \mathbb{Z})$.

Recall that $A(X)$ is the domain of the Donaldson invariant.

Definition 3.7. We define
\begin{align*}
\Psi^{tw, (1)}_{X,f} : A(X) \otimes H_{\text{odd}}(X; \mathbb{Z}) &\to H^*(\text{Pic}(B\Gamma); \mathbb{Q}), \\
\Psi^{tw, (1)}_{X,f}([M_1], \ldots, [M_d]; \alpha) &= \frac{1}{2 \cdot 4^0 \mu^t_w(\alpha)/[V(\tilde{E}; \Sigma_0, M_1, \ldots, M_d)]}
\end{align*}
if there is an $SU(2)$-vector bundle $E$ over $X$ with $c_2(E)$ odd and with $\dim \mathfrak{M}(E) = \sum_{j=1}^{d}(4 - \dim M_j) + 1$. Here $d_0$ is the number of homology classes $[M_j]$ of degree 0.

We put $\Psi^{tw, (1)}_{X,f}([M_1], \ldots, [M_d]; \alpha) = 0$ otherwise.
Remark 3.8. (1) $\Psi_{X,f}^{tw,(1)}$ is independent of $f$ when $\pi_1(X) \cong \mathbb{Z}$, as in Remark 3.6.

(2) We can define the twisted Donaldson invariant

$$
\Psi_{X,f}^{tw,(2)} : A(X) \otimes H_{odd}(X; \mathbb{Z}) \to H^*(\text{Pic}(B\mathcal{G}); \mathbb{Q})
$$

in the same way, using an $SU(2)$ vector bundle $E$ on $X$ with $c_2(E)$ odd and with $\text{dim } \mathcal{M}(E) = \sum_{j=1}^d (4 - \text{dim } M_j) + 2$. But this invariant is always trivial by the formula for $\mu_{tw}^{\mathbb{Q}}$ in lemma 3.6.

(3) As stated in proposition 2.6, $\left[ V(\hat{E}; \Sigma_0, M_1, \ldots, M_d) \right] \in H_3(\mathfrak{B}^*(\hat{E}); \mathbb{Z})$ depends on the homotopy class $[M_j : S^1 \to X] \in \pi_1(X)$ with $\text{dim } M_j = 1$. So if $\pi_1(X)$ is not commutative, $H_1(X; \mathbb{Z})$ in $A(X)$ should be replaced with $\pi_1(X)$.

3.1.2. Construction of $\Psi_{X,f}^{tw,(3)}$. Let us try to define a twisted Donaldson invariant

$$
\Psi_{X,f}^{tw,(3)} : A(X) \otimes H_{odd}(X; \mathbb{Z}) \to H^*(\text{Pic}(B\mathcal{G}); \mathbb{Q})
$$

using an $SU(2)$-vector bundle $E$ with $\text{dim } \mathcal{M}(E) = \sum_{j=1}^d (4 - \text{dim } M_j) + 3$. We cannot apply proposition 2.6 straightforwardly to the 3 dimensional manifold $V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)$. Actually it may not define a homology class in $H_3(\mathfrak{B}^*(\hat{E}); \mathbb{Z})$ which is independent of $g$ (see the last argument in the proof of proposition 2.6).

To avoid this issue, we use a submanifold in $\mathfrak{B}^*(\hat{E})$ dual to (the relevant part of) $\mu_{tw}^{\mathbb{Q}}(\alpha)$. It follows from lemma 3.5 that $\Psi_{X,f}^{tw,(3)}([M_1], \ldots, [M_d], \alpha)$ should be of the form for $\alpha \in H_1(X; \mathbb{Z})$

$$
-\frac{1}{2 \cdot 4^{d_0}} \left( \mu(\alpha), [V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)] \right) \eta \in H^1(\text{Pic}(B\mathcal{G}); \mathbb{Q}),
$$

where $d_0$ is the number of homology classes $[M_j]$ of degree 0. As explained in Section 2, a dual submanifold $V_\ell$ of $\mu(\alpha)$ in $\mathfrak{B}^*(\hat{E})$ is obtained by the map defined by holonomies around $\ell$, where $\ell$ is a loop representing $\alpha$. By proposition 2.7, the intersection

$$
V(\hat{E}; \Sigma_0, M_1, \ldots, M_d, \ell) := V_\ell \cap V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)
$$

defines a well-defined 0-dimensional homology class $[V(\hat{E}; \Sigma_0, M_1, \ldots, M_d, \ell)] \in H_0(\mathfrak{B}^*(\hat{E}); \mathbb{Z}) \cong \mathbb{Z}$. So it is natural to define

$$
\Psi_{X,f}^{tw,(3)}([M_1], \ldots, [M_d]; \alpha) = -\frac{1}{2 \cdot 4^{d_0}} [V(\hat{E}; \Sigma_0, M_1, \ldots, M_d, \ell)] \eta.
$$

On the other hand, for $\alpha \in H_3(X; \mathbb{Z})$, we put $\Psi_{X,f}^{tw,(3)}([M_1], \ldots, [M_d], \alpha) = 0$ by Lemma 3.5.

Definition 3.9. We define

$$
\Psi_{X,f}^{tw,(3)} : A(X) \otimes H_{odd}(X; \mathbb{Z}) \to H^*(\text{Pic}(B\mathcal{G}); \mathbb{Q}),
$$

$$
\Psi_{X,f}^{tw,(3)}([M_1], \ldots, [M_d]; \alpha) = -\frac{1}{2 \cdot 4^{d_0}} [V(\hat{E}; \Sigma_0, M_1, \ldots, M_d, \ell)] \eta.
$$
if \( \alpha \in H_1(X;\mathbb{Z}) \) and there is an \( SU(2) \)-vector bundle \( E \) with \( c_2(E) \) odd and with \( \dim \mathfrak{M}(E) = \sum_{j=1}^{d} (4 - \dim M_j) + 3 \).

We put \( \Psi_{X,f}^{tw,(3)}([M_1], \ldots, [M_d]; \alpha) = 0 \) otherwise.

Remark 3.10. (i) For \( r = 1, 3 \) we can write

\[
\Psi_{X,f}^{tw,(r)}([M_1], \ldots, [M_d]; \alpha) = -\Psi_{X,odd}([M_1], \ldots, [M_d], \alpha)\eta
\]

if \( \alpha \in H_{4-r}(X;\mathbb{Z}) \) and \( \Psi_{X,f}^{tw,(r)}([M_1], \ldots, [M_d]; \alpha) = 0 \) if \( \alpha \in H_r(X;\mathbb{Z}) \).

See (2.11) for the definition of \( \Psi_{X,odd} \). Therefore \( \Psi_{X,f}^{tw,(r)} \) coincides with the known invariants of \( X \). But we emphasize that we have obtained \( \mu(\alpha) \cup \eta \) as (part of) the Chern character of the index of a family of Dirac operators. To define the non-commutative version of the twisted Donaldson invariants in section 3 it is necessary that the twisted \( \mu \) map is defined as the Chern character of the index of a family of Dirac operators.

(ii) Since \( \Psi_{X,f}^{tw,(r)} \) are written in terms of the classical Donaldson invariant \( \Psi_X \), \( \Psi_{X,f}^{tw,(r)} \) are also homomorphisms and descend to maps on \( H_1(X;\mathbb{Z}) \). See remark 2.9.

(iii) It seems possible to generalize our construction of the twisted Donaldson invariants over non-spin 4-manifolds \( X \), using \( U(2) \)-vector bundles \( E \) with \( c_1(E) \equiv w_2(X) \mod 2 \) and with \( c_2(E) \) odd. We can still construct the universal bundle on \( X \times \mathbb{B}^+(E) \) of \( E \) and proceed in a similar way.

The construction of the twisted Donaldson invariants for a non-spin 4-manifold will be a bit more complicated. We have to choose a \( U(2) \)-bundle \( E \) with \( c_1(E) = w_2(X) \mod 2 \), and hence we need to fix an integral lift of \( w_2(X) \). In the case we have to check that the twisted Donaldson invariants are independent of the choice of the integral lift. Also the formula of lemma 3.5 in the non-spin case is more complicated than the spin case.

3.2. Non triviality of the invariants. Let us verify that our twisted invariants are non trivial by presenting the following non trivial results by use of them:

Theorem 3.11. Let \( Y \) be a simply connected, spin, algebraic surface with \( b^+ > 1 \) and \( m \) be a non-negative integer. Then \( X = Y \# (\#^m S^1 \times S^3) \) cannot admit any connected sum decomposition as \( X = X_1 \# X_2 \) with \( b^+(X_i) > 0 \).

Theorem 3.11 follows from proposition 3.13 below with the Donaldson’s fundamental result on non vanishing of the invariants for algebraic surfaces.

Let us say that \( Y_1 \) and \( Y_2 \) be an exotic pair, if they are homeomorphic but have different smooth structures.

Theorem 3.12. Let \( Y_1 \) and \( Y_2 \) be a pair of compact spin four manifolds with \( b^+(Y_i) > 1 \), which are mutually homeomorphic. Moreover assume that \( \Psi_{Y_1,odd} \) is trivial, but \( \Psi_{Y_2,odd} \) is not trivial, so that they consist of an exotic pair. Then the pair \( (Y_1 \# (\#^m S^1 \times S^3), Y_2 \# (\#^m S^1 \times S^3)) \) is also exotic.
Theorem 3.12 is a consequence of proposition 3.13 and lemma 3.15 below. Notice that the statement is quite unlikely to hold, if we replace $S^1 \times S^3$ by $S^2 \times S^2$.

In the case when $Y_1$ and $Y_2$ are simply connected and $m = 1$, theorem 3.12 follows from proposition in [24 p.494]. The authors would like to thank Kouichi Yasui for informing the authors about this. Our result can be applied to the case when $Y_1$, $Y_2$ are not simply connected and $m > 1$.

3.2.1. Computation of the invariants. Later on the rest of section 3, we always assume that all 4-manifolds $Y$ or $X$ are compact and spin with $b^+ > 1$, without mention.

**Proposition 3.13.** Let us put $X := Y \#(\#^m S^1 \times S^3)$, where $m$ is a positive integer. Then the formula

$$\Psi_{X, \ell}^{\mathrm{tw}, (3)}([M_1], \ldots, [M_d], [\ell_1], \ldots, [\ell_{m-1}]: [\ell_m]) = -\Psi_{Y, \ell}([M_1], \ldots, [M_d])$$

holds, where $[M_1], \ldots, [M_d] \in A(Y)$, $\ell_1, \ldots, \ell_m$ are loops in $\#^m S^1 \times S^3$ which generate $H_1(\#^m S^1 \times S^3; \mathbb{Z})$, and $\eta$ is the generator of $H^1(\text{Pic}(B\Gamma); \mathbb{Z}) \cong \mathbb{Z}$.

**Proof.** We will give a proof for the case $m = 1$. We can prove the statement for the general case similarly.

Put $X = Y \# S^1 \times S^3$. Take an $SU(2)$-vector bundle $E$ on $X$ with $c_2(E)$ odd and homology classes $[M_1], \ldots, [M_d]$ such that

$$\dim \mathfrak{M}(E) = \sum_{j=1}^d (4 - \dim M_j) + 3.$$  

Let $\ell$ be a loop which represents a generator of $H_1(S^1 \times S^3; \mathbb{Z})$. Let us verify the formula

$$\frac{1}{2} \# V(\hat{E}; \Sigma_0, M_1, \ldots, M_d, \ell) = \Psi_Y([M_1], \ldots, [M_d]).$$

Here $[\Sigma_0] = PD(e)$ and $\hat{E}$ is the $U(2)$-vector bundle over $\hat{X} = X \# \mathbb{CP}^2$ with $c_1(\hat{E}) = e$ and with $c_2(\hat{E}) = c_2(E)$ as before. Recall that

$$V(\hat{E}; \Sigma_0, M_1, \ldots, M_d, \ell) = V(\hat{E}; \Sigma_0, M_1, \ldots, M_d) \cap V_\ell$$

with $V_\ell = (h'_\ell)^{-1}(1)$, where $h'_\ell$ is a perturbation of the section $h_\ell : \mathfrak{B}^*_{\nu(\ell)} \to \text{ad} \mathfrak{B}^*_{\nu(\ell)}$ defined by holonomies around $\ell$. (See section 2)

To verify (3.4), take a Riemann metric $\hat{g}_T$ on $\hat{X}$ such that $\hat{X}$ has a long neck $S^3 \times [0, T]$ for $T > 0$

$$\hat{X} = (\hat{Y} \setminus D_1) \cup (S^3 \times [0, T]) \cup ((S^1 \times S^3) \setminus D_2).$$

Here $D_1, D_2$ are small 4-balls in $\hat{Y}$, $S^1 \times S^3$ with $D_2 \cap \ell = \emptyset$. Take a sequence $[A_n] \in \hat{V}(\hat{E}, \hat{g}_{T_n}; \Sigma_0, M_1, \ldots, M_d) \cap \hat{h}_\ell^{-1}(1)$ with $T_n \to \infty$. Here $\hat{h}_\ell : \mathfrak{B}_{\nu(\ell)} \to SU(2)$ is the unperturbed map defined by holonomies, and $\hat{V}(\hat{E}, \hat{g}_{T_n}; \Sigma_0, M_1, \ldots, M_d)$ is the pull-back of the intersection to the configuration space $\mathfrak{B}(\hat{E})$ of framed connections.

A standard process verifies that it converges after passing to a subsequence

$$[A_n] \to ([A], [B]) \in \hat{V}(\hat{F}; \Sigma_0, M_1, \ldots, M_d) \times (\mathfrak{M}(F_0) \cap \hat{h}_\ell^{-1}(1)).$$
Here $\tilde{F}$ is the $U(2)$-bundle on $\tilde{Y}$ with $c_2(\tilde{F}) = c_2(\tilde{E})$ and with $c_1(\tilde{F}) = e$ and $\tilde{M}(\tilde{F}_0)$ is the moduli space of framed flat connections on the trivial bundle $F_0$ on $S^1 \times S^3$. The map gives an identification

$$\tilde{h}_\ell : \tilde{M}(\tilde{F}_0) \xrightarrow{\cong} SU(2).$$

In particular, $\tilde{h}_\ell$ is transverse to 1 without perturbation, and hence the intersection $\tilde{V}(\tilde{E}, \tilde{g}_T; \Sigma_0, M_1, \ldots, M_d) \cap \tilde{h}_\ell^{-1}(1)$ is transverse for large $T > 0$. Moreover $[B]$ must be the gauge equivalent class of the trivial flat connection. It follows from a well known argument that gluing ASD on $Y$ and the trivial flat connection on $S^1 \times S^3$ gives an $SO(3)$-equivariant identification

$$\tilde{V}(\tilde{E}, \tilde{g}_T; \Sigma_0, M_1, \ldots, M_d) \cap \tilde{h}_\ell^{-1}(1) \cong \tilde{V}(\tilde{F}; \Sigma_0, M_1, \ldots, M_d).$$

Here we have used the fact that there is no obstruction to gluing instantons on $\tilde{Y}$ and the trivial connection on $S^1 \times S^3$ since $b^+(S^1 \times S^3) = 0$. The above identification implies (3.4).

q.e.d.

**Proposition 3.14.** Let us fix a homomorphism $f : \pi_1(X) \to \Gamma := \mathbb{Z}$. Suppose that a connected sum decomposition $X = X_1 \# X_2$ exists with $b^+(X_i) > 0$. Then the twisted Donaldson invariant $\Psi_{X, f}^{tw,(3)}$ is identically zero.

**Proof.** For $\alpha \in H_3(X; \mathbb{Z})$, $\Psi_{X, f}^{tw,(3)}([M_1], \ldots, [M_d]; \alpha) = 0$ by definition. We have to show that for $\alpha \in H_1(X; \mathbb{Z})$, $\Psi_{X, f}^{tw,(3)}([M_1], \ldots, [M_d]; \alpha) = 0$. We have

$$\Psi_{X, f}^{tw,(3)}([M_1], \ldots, [M_d]; \alpha) = -\Psi_{X, odd}([M_1], \ldots, [M_d], \alpha)\eta$$

as explained in remark 3.10. The Donaldson invariant $\Psi_X([M_1], \ldots, [M_d], \alpha)$ is zero if $X = X_1 \# X_2$ with $b^+(X_j) > 0$ for $j = 1, 2$, hence the right hand side in the above formula is zero. See [30] and theorem 6.4 of [13].

q.e.d.

We also have the following vanishing result which is needed for the proof of theorem 3.12.

**Lemma 3.15.** Assume $\Psi_{X, odd}$ is trivial. Then $\Psi_{X, f}^{tw,(3)}$ is trivial, where $X = Y \# (\#^m S^1 \times S^3)$ and $m$ is a positive integer.

**Proof.** The proof is an easy consequence of a standard dimension counting argument and proposition 3.13. We omit the detail.

q.e.d.

3.2.2. Examples. Recall that we have assumed that all four manifolds $Y$ or $X$ are compact and spin with $b^+ > 1$, otherwise stated.

(1) Let $X = Y \# (\#^m S^1 \times S^3)$ be as above. Moreover assume that $Y$ is an algebraic surface. For example, we can take the hyperplane surface $S_d$ in $\mathbb{CP}^3$ of degree $d \geq 4$ with $d \equiv 0 \mod 2$. Then $\Psi_{X, f}^{tw,(3)}$ is non-trivial.

For $d \geq 6$ with $d$ even, $S_d \# (\#^m S^1 \times S^3)$ is homeomorphic to $(\#^k K3) \# (\#^l S^2 \times S^2) \# (\#^m S^1 \times S^5)$ for some $k, l > 0$, but they are not diffeomorphic to each other.
The argument goes as follows. It is known that $S_d$ is simply connected and spin for $d$ even. Let $h \in H_2(Y; \mathbb{Z})$ be a hyperplane class in $Y$. Then we have

$$\Psi_{X,f}^{tw, (3)} \neq 0.$$  

This follows from proposition 3.13 with a fact $\Psi_{S_d}(h, \ldots, h) > 0$ for all large $n$, where $c_2(E)$ varies with respect to $n$ (See Theorem C of [12]). In particular $X$ does not admit a connected sum decomposition $X = X_1 \# X_2$ with $b^+(X_1), b^+(X_2) > 0$ by proposition 3.14.

If $d$ is even and if $d \geq 6$, the intersection form of $S_d$ is isomorphic to that of the connected sum $(\#^k K3)\#(\#^l S^2 \times S^2)$ of copies of $K3$ with copies of $S^2 \times S^2$ for some $k, l \in \mathbb{Z}_{>0}$. (See p.13 of [14].) Hence, by Freedman’s theory, $X = S_d\#(\#^m S^1 \times S^3)$ is homeomorphic to $(\#^k K3)\#(\#^l S^2 \times S^2) \# (\#^m S^1 \times S^3)$. On the other hand, it follows from the above that $X$ can not be diffeomorphic to $(\#^k K3)\#(\#^l S^2 \times S^2)\#(\#^m S^1 \times S^3)$ by proposition 3.14.

(2) Let $E(n)_{p,q}$ be Elliptic surfaces over $\mathbb{C}P^1$ with the Euler number $\chi = 12n > 0$ and multiple torus fibers of multiplicities $p$ and $q$ respectively. There are infinitely many $(p, q)$ such that $E(n)_{p,q} \#(\#^m S^1 \times S^3)$ are all homeomorphic but have different smooth structures from each other.

If $n$ is even, if $p, q$ are odd and $\gcd(p, q) = 1$, then $E(n)_{p,q}$ is simply connected, spin with $b^+ = 2n - 1 > 1$, and hence satisfy the conditions above. Moreover, $E(n)_{p,q}$ and $E(n)_{p',q'}$ are homeomorphic to each other. On the other hand, the Donaldson invariants of $E(n)_{p,q}$ are calculated and it shows that if $E(n)_{p,q}$ and $E(n)_{p',q'}$ are diffeomorphic to each other, then $p = p'$ and $q = q'$. See [16] [24] [31] [32].

Using the calculation of the Donaldson invariants and proposition 3.14, if $(p, q) \neq (p', q')$, we can see that $E(n)_{p,q} \#(\#^m S^1 \times S^3)$ and $E(n)_{p',q'} \#(\#^m S^1 \times S^3)$ are homeomorphic but have different smooth structures.

(3) Using Seiberg-Witten theory, we can prove the same result by a quite parallel argument as below.

Let $Y$ be a 4-manifold with $b^+(Y) > 0$ and take a spin$^c$ structure of $Y$. For simplicity, suppose that the dimension of the moduli space of solutions to the SW equations on $Y$ associated with the spin$^c$ structure is $0$. Then the SW invariant is the number of solutions with sign. On $Y \#(S^1 \times S^3)$, consider the connected sum of the spin$^c$ structure of $S^1 \times S^3$. (Note that $S^1 \times S^3$ has a unique spin$^c$ structure up to isomorphisms.) Then the SW moduli space of $Y \#(S^1 \times S^3)$ has dimension 1.

For each connection of the determinant line bundle of the spinor bundle on $Y \#(S^1 \times S^3)$, we get the holonomy around the circle $S^1 \times \{pt\}$. It induces a map from the SW moduli space on $Y \#(S^1 \times S^3)$ to $U(1)$. The inverse image of a generic point in $U(1)$ by this map is a finite set. Counting the elements of the inverse image with sign, we get an invariant of $Y \#(S^1 \times S^3)$. As proposition 3.13 we can prove that the invariant of $Y \#(S^1 \times S^3)$ is equal to the SW invariant of $Y$. 

Using this, we can show that for $d \geq 6$ with $d$ even, $S_d\#(S^1 \times S^3)$ is not diffeomorphic to a connected sum of copies of $K3$, $S^2 \times S^2$ and $S^1 \times S^3$ as above. This discussion can be extended to $Y\#(\#^mS^1 \times S^3)$.

Remark 3.16. So far we have assumed that $Y$ is spin in the previous examples, since the twisted Donaldson invariant is defined for spin 4-manifolds. But, using the Donaldson invariants, we can get the similar examples for non-spin 4-manifolds $Y$.

3.2.3. More examples of exotic smooth structures. We can generalize the results in the previous subsection as follows. In this subsection 4-manifolds are not necessarily spin.

(1) Let $Y$ be a closed 4-manifold with $b^+(Y) > 1$, and $Z$ be a closed 4-manifold with $\pi_1(\bar{Z}) \cong \mathbb{Z}^m$ and $b^+(\bar{Z}) = 0$.

Take loops $\ell_1, \ell_2, \ldots, \ell_m$ in $Z$ which generate $\pi_1(\bar{Z})$. Then a paralell argument to proposition 3.13 gives the equality

$$\Psi_{\bar{Y} \# Z}([M_1], \ldots, [M_d], [\ell_1], \ldots, [\ell_m]) = \Psi_Y([M_1], \ldots, [M_d])$$

for $[M_1], \ldots, [M_d] \in H_{\leq 3}(Y; \mathbb{Z})$. This produces the following statement:

Let $Y$ and $Y'$ be closed and 4-manifolds with $b^+ > 1$, which are mutually homeomorphic. If the Donaldson invariant over $Y$ vanishes but the one over $Y'$ does not so that they are exotic. Then $(Y \# Z, Y' \# Z)$ also consists of an exotic pair.

(2) We can remove the assumption on $\pi_1(Z)$ using the Seiberg-Witten theory. Let $Y, Y', Z$ be as above, but $\pi_1(Z)$ is not necessarily isomorphic to $\mathbb{Z}^m$.

If the SW invariant of $Y$ vanishes but that of $Y'$ does not, then we can show that $Y \# Z$ and $Y' \# Z$ also form an exotic pair.

If $b_1(Z) = k$ we take $k$ loops in $Z$ which are generators of $H_1(Z; \mathbb{Z})/\text{Tor}$ and consider holonomies around the loops. Then we get a map from the moduli space to $U(1) \times \cdots \times U(1)$. We cut down the moduli space by this map. (If $k = 0$, we do not need to cut down the moduli space.) Then the proof goes in a parallel way to (3) of section 3.2.2.

(3) Both the Donaldson and SW invariants vanish over $Y_1 \# Y_2 \# Z$ with $b^+(Y_1), b^+(Y_2) > 0$ and $b^+(Z) = 0$. The Bauer-Furuta invariant is a refinement of the SW invariant, and it is not always trivial over $Y_1 \# Y_2 \# Z$.

Let $Y_1, Y_2$ are simply connected, symplectic 4-manifolds with $b^+ \equiv 3 \mod 4$, and put $Z = (\#^m\mathbb{CP}^2) \# (\#^mS^1 \times S^3)$ with $l \geq 1, m \geq 0$. Freedman’s theory tells us that $Y_1 \# Y_2 \# Z$ is homeomorphic to

$$W := (\#^{b^+(Y_1)+b^+(Y_2)}\mathbb{CP}^2) \# (\#^{b^-(Y_1)+b^-(Y_2)}\mathbb{CP}^2) \# (\#^mS^1 \times S^3).$$

Then we can verify that

$Y_1 \# Y_2 \# Z$ is not diffeomorphic to $W$.

Let us use the BF invariant to distinguish these exotic smooth structures. It is known that the invariant is not trivial for $Y_1 \# Y_2$. Combining this with corollary 8 of [18], the BF invariant of $Y_1 \# Y_2 \# Z$ turns out to be non-trivial.
On the other hand, the BF invariant of $W$ is trivial because $W$ has a positive scalar curvature metric. Therefore they are not diffeomorphic to each other.

If we replace $S^1 \times S^3$ with $S^2 \times S^2$ or $T^2 \times S^2$, the above discussion does not work since $b^+(S^2 \times S^2), b^+(T^2 \times S^2) > 0$. It seems that there is no example of an exotic smooth structure of a 4-manifold of the form $Y \#(S^2 \times S^2)$ or $Y \#(T^2 \times S^2)$.

Instead of $S^2 \times S^2$ and $T^2 \times S^2$, let us consider $\Sigma_g \times \Sigma_h$, where $\Sigma_g, \Sigma_h$ are oriented, closed surface of genus $g, h$. Let $Y_1, Y_2$ be simply connected symplectic 4-manifolds with $b^+(Y) \equiv 3 \mod 4$. In [22], it is proved that if $g, h$ are odd the Bauer-Furuta invariants of $Y_1 \# \Sigma_g \times \Sigma_h, Y_1 \# Y_2 \# \Sigma_g \times \Sigma_h$ are non-trivial. Using this fact, we can show that there are exotic smooth structures of $Y_1 \# \Sigma_g \times \Sigma_h \# Z, Y_1 \# Y_2 \# (\Sigma_g \times \Sigma_h) \# Z$, where $Z = (\pi_1 \mathbb{CP}^2)^\# (\#^m S^1 \times S^3)$ with $l \geq 1, m \geq 0$. See also [19] similar results.

3.3. Higher rank case. Recall that we assume that all four manifolds $Y$ and $X$ are compact and spin with $b^+ > 1$, without mention.

3.3.1. Construction of the twisted Donaldson invariants. Let us fix a homomorphism

$$f : \pi_1(X) \to \Gamma := \mathbb{Z}^m.$$

Let $L \to B\Gamma \times \text{Pic}(B\Gamma)$ be the universal line bundle. The first Chern class of $L$ is given by the following formula

$$c_1(L) = \omega_1 \cup \eta_1 + \cdots + \omega_m \cup \eta_m.$$  

Here $\{\omega_j\}_j$ is a basis of $H^1(B\Gamma; \mathbb{Z})$ and $\{\eta_j\}_j$ is the basis of $H^1(\text{Pic}(B\Gamma); \mathbb{Z})$ which is induced by $\{\omega_j\}_j$.

Take an $SU(2)$-vector bundle $E$ on $X$ with $c_2(E)$ odd. As before we take the $U(2)$-vector bundle $\tilde{E}$ on $\tilde{X} = X \# \mathbb{CP}^2$ with $c_1(\tilde{E}) = e$ and with $c_2(\tilde{E}) = c_2(E)$. Then we have the universal bundle

$$\tilde{E} \to \tilde{X} \times \mathcal{B}^*(\tilde{E}).$$

Let us introduce a twisted $\mu$ map

$$\mu^\text{tw}_\Gamma : H_{\text{odd}}(X; \mathbb{Z}) \otimes H_1(B\Gamma; \mathbb{Z}) \to \lim_B H^*(B \times \text{Pic}(B\Gamma); \mathbb{Q}),$$

where $B$ runs over compact subsets in $\mathcal{B}^*(\tilde{E})$. Take a homology class $\alpha = [M] \in H_{\leq 3}(X; \mathbb{Z})$ realized by a submanifold $M \subset X$. We can regard $M$ as a submanifold in $\tilde{X}$. Take $\beta = [j : S^1 \to B\Gamma] \in H_1(B\Gamma; \mathbb{Z})$, where $j$ is a continuous map. Let us consider a vector bundle

$$\tilde{E}\_f^{\text{tw}} : = \tilde{E} \boxtimes_X (\hat{f} \times id)^*L \boxtimes_{\text{Pic}} (j \times id)^*L \to \tilde{X} \times S^1 \times \mathcal{B}^*(\tilde{E}) \times \text{Pic}(B\Gamma)$$

where $\hat{f} : \tilde{X} \to B\Gamma$ is the continuous map corresponding to the group homomorphism $f : \pi_1(X) = \pi_1(\tilde{X}) \to \Gamma$.

Fix a spin structure on $M \times S^1$. Coupling the Dirac operator over $M \times S^1$ with $\tilde{E}_f^{\text{tw}} |_{M \times S^1 \times \mathcal{B}^*(\tilde{E}) \times \text{Pic}(B\Gamma)}$, we obtain the family of twisted Dirac operators $\mathcal{D}_{M \times S^1, f}$ over $M \times S^1$ parametrized by $\mathcal{B}^*(\tilde{E}) \times \text{Pic}(B\Gamma)$. Then we define the index

$$\text{Ind}_B \mathcal{D}_{M \times S^1, f} \in K^*(B \times \text{Pic}(B\Gamma))$$
for each compact subset $B \subset \mathcal{B}^*(\hat{E})$.

**Definition 3.17.**

$$\mu^\text{tw}_f(\alpha, \beta) \equiv \{\text{ch}(\text{Ind}_B(\mathbb{D}_{M \times N, f})))\}_B \in \lim_{B} H^*(B \times \text{Pic}(BG); \mathbb{Q}),$$

where $B$ runs over the compact subsets in $\mathcal{B}^*(\hat{E})$.

**Lemma 3.18.** Under the above situation, the equality

$$\mu^\text{tw}_f(\alpha, \beta) = \{\text{ch}(\hat{E}\boxtimes_X \{\hat{f} \times \text{id})^*\mathbb{L}_B \boxtimes \text{Pic} \ (j \times \text{id})^*\mathbb{L}_B\}/[M \times S^1]\}
\cup \{\text{ch}(\hat{E}\boxtimes_X \{\hat{f} \times \text{id})^*\mathbb{L}_B\}/[M \times S^1]\}/[M \times S^1]$$

holds, where the right hand side is the image of the cohomology class by the natural map $H^*(\mathcal{B}^*(E) \times \text{Pic}(BG); \mathbb{Q}) \to \lim_{B} H^*(B \times \text{Pic}(BG); \mathbb{Q})$.

Moreover $\mu^\text{tw}_f(\alpha, \beta)$ depends only on $\alpha, \beta$ so that it is independent of choices of representatives $M$ and $j : S^1 \to BG$ for $\alpha$ and $\beta$ respectively, and of spin structure on $M \times S^1$.

**Proof.** The Atiyah-Singer index theorem for the family gives a formula

$$\mu^\text{tw}_f(\alpha, \beta) = \text{ch}(\hat{E}\boxtimes_X \{\hat{f} \times \text{id})^*\mathbb{L}_B \boxtimes \text{Pic} \ (j \times \text{id})^*\mathbb{L}_B\}/[M \times S^1].$$

Since $\dim M \leq 3$, the equalities $\hat{A}(M \times S^1) = \hat{A}(M)\hat{A}(S^1) = 1$ hold. So

$$\mu^\text{tw}_f(\alpha, \beta) = \text{ch}(\hat{E}\boxtimes_X \{\hat{f} \times \text{id})^*\mathbb{L}_B \boxtimes \text{Pic} \ (j \times \text{id})^*\mathbb{L}_B\}/[M \times S^1]$$

$$= \{\text{ch}(\hat{E}\boxtimes_X \{\hat{f} \times \text{id})^*\mathbb{L}_B\}/[M \times S^1] \cup \{(j \times \text{id})^*\text{ch}(\mathbb{L})/[S^1]\}\}
\cup \{\text{ch}(\hat{E}\boxtimes_X \{\hat{f} \times \text{id})^*\mathbb{L}_B\}/[M \times S^1] \cup \{c_1(\mathbb{L})/\beta\}.\}

Here we have used the equalities

$$(j \times \text{id})^*c_1(\mathbb{L})/[S^1] = c_1(\mathbb{L})/\beta, \ (j \times \text{id})^*c_1(\mathbb{L})^n/[S^1] = 0 \ (n \geq 2).$$

The second equality follows from the formula (3.5). This formula implies that $\mu^\text{tw}_f(\alpha, \beta)$ is independent of choices of representatives $M, j$ of the homology classes and spin structure on $M \times S^1$.

Let $\Sigma_0$ be a surface in $\hat{X}$ with $[\Sigma_0] = PD(e)$, and $V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)$ be the intersection defined as (2.5).

**Definition 3.19.** Let us fix a homomorphism $f : \pi_1(X) \to \Gamma := \mathbb{Z}^m$.

For $r = 1, 2$ we define

$$\Psi_{\chi, f}^{\text{tw}, (r)} : A(X) \otimes H_{\text{odd}}(X; \mathbb{Z}) \otimes H_1(BG; \mathbb{Z}) \to H^*(\text{Pic}(BG); \mathbb{Q}),$$

$$\Psi_{\chi, f}^{\text{tw}, (r)}([M_1], \ldots, [M_d]; \alpha, \beta) := \frac{1}{2 \cdot 4^d} \mu^\text{tw}_f(\alpha, \beta)/[V(\hat{E}; \Sigma_0, M_1, \ldots, M_d)]$$

if there is an $SU(2)$-vector bundle $E$ with $c_2(E)$ odd and with $\dim \mathcal{M}(E) = \sum_{j=1}^{d}(4 - \dim M_j) + r$. Here $d_0$ is the number of homology classes $[M_j]$ of degree $0$.

We put $\Psi_{\chi, f}^{\text{tw}, (r)}([M_1], \ldots, [M_d]; \alpha, \beta) = 0$ otherwise.
Lemma 3.20. Let $\beta \in H_1(B\Gamma;\mathbb{Z})$ and $c \in H_3(\mathcal{B}^+(\hat{E});\mathbb{Z})$. Then the equalities hold:

$$\mu^\text{tw}(\alpha, \beta)/c = \begin{cases} -\langle \mu(\alpha), c \rangle \{c_1(\mathbb{L})/\beta\}, & \text{for } \alpha \in H_1(X;\mathbb{Z}), \\ 0, & \text{for } \alpha \in H_3(X;\mathbb{Z}). \end{cases}$$

Proof. Take $\alpha = [\ell] \in H_1(X;\mathbb{Z})$, $\beta \in H_1(B\Gamma;\mathbb{Z})$, $c \in H_3(\mathcal{B}^+(\hat{E});\mathbb{Z})$. One can check $c_1(\hat{E}|_{\ell\times\mathcal{B}^+(\hat{E})}) = 0$ as in the proof of lemma 3.5. From lemma 3.18 we have the equalities

$$\mu^\text{tw}(\alpha, \beta)/c = \{\text{ch}(\hat{\mathcal{E}})(\hat{f} \times id)^*\text{ch}(\mathbb{L})/\alpha \times c\} \cup \{c_1(\mathbb{L})/\beta\}$$

$$= \left\{ (2 - c_2(\hat{\mathcal{E}}) + \chi_{\geq 4}(\hat{\mathcal{E}})) \left( 1 + (\hat{f} \times id)^*c_1(\mathbb{L}) + \frac{1}{2!}(\hat{f} \times id)^*c_1(\mathbb{L})^2 + \cdots \right) / \alpha \times c \right\}$$

$$\cup \{c_1(\mathbb{L})/\beta\}$$

$$= -\langle c_2(\hat{\mathcal{E}})/\alpha, c \rangle \{c_1(\mathbb{L})/\beta\} = -\langle \mu(\alpha), c \rangle \{c_1(\mathbb{L})/\beta\}.$$ 

One can check that $\mu^\text{tw}(\alpha, \beta)/c = 0$ vanishes by a similar computation, if $\alpha \in H_3(X;\mathbb{Z})$. q.e.d.

This lemma leads us to the following definition.

Definition 3.21. We define

$$\Psi_{X,f}^{\text{tw}(3)} : A(X) \otimes H_{\text{odd}}(X;\mathbb{Z}) \otimes H_1(B\Gamma;\mathbb{Z}) \to H^*(\text{Pic}(B\Gamma);\mathbb{Z})$$

by the following formulas. Let $[M_1],\ldots,[M_d] \in A(X)$ and $\beta \in H_1(B\Gamma;\mathbb{Z})$. Then:

$$\Psi_{X,f}^{\text{tw}(3)}([M_1],\ldots,[M_d];\alpha, \beta)$$

$$= \begin{cases} -\Psi_{X,\text{odd}}([M_1],\ldots,[M_d],\alpha)\{c_1(\mathbb{L})/\beta\}, & \text{for } \alpha \in H_1(X;\mathbb{Z}), \\ 0, & \text{for } \alpha \in H_3(X;\mathbb{Z}). \end{cases}$$

Remark 3.22. $\Psi_{X,f}^{\text{tw}(3)}$ is again independent of $f : \pi_1(X) \to \Gamma$.

Next we define $\Psi_{X,f}^{\text{tw}(4)}$. It turns out that they do depend on $f$.

Lemma 3.23. Let $\beta \in H_1(B\Gamma;\mathbb{Z})$ and $c \in H_4(\mathcal{B}^+(\hat{E});\mathbb{Z})$. Then we have the equalities

$$\mu^\text{tw}(\alpha, \beta)/c = \begin{cases} -\langle \mu([pt]), c \rangle \{(\hat{f} \times id)^*(c_1(\mathbb{L}))/\alpha\} \cup \{c_1(\mathbb{L})/\beta\}, & \text{for } \alpha \in H_1(X;\mathbb{Z}), \\ -\langle \mu([pt]), c \rangle \{(\hat{f} \times id)^*(c_1(\mathbb{L})^2)/\alpha\} \cup \{c_1(\mathbb{L})/\beta\}, & \text{for } \alpha \in H_3(X;\mathbb{Z}). \end{cases}$$
Proof. Let \( \alpha = [M] \in H_1(X; \mathbb{Z}) \), \( \beta \in H_1(B\Gamma; \mathbb{Z}) \) and \( c \in H_4(\mathbb{R}^*; \mathbb{Z}) \).

From (3.25), we have
\[
(\hat{f} \times id)^* c_1(L)^n / \alpha = 0
\]
for \( n \neq 1 \). Using this, \( c_1(\hat{E})|_{M \times \mathbb{R}^*} = 0 \) and Lemmas 3.11 we get
\[
\mu_1^{bw}(\alpha, \beta)/c
\]
\[
= (\hat{f} \times id)^* c_1(L)/\alpha \cap \{c_1(L)/\beta\}
\]
\[
= \left\{ 2 - c_2(\hat{E}) + c_2(\hat{E}) \left( 1 + (\hat{f} \times id)^* c_1(L) + \frac{1}{2!} (\hat{f} \times id)^* c_1(L)^2 + \cdots \right) \right\} / \alpha \cap \{c_1(L)/\beta\}
\]
\[
= - (\hat{f} \times id)^* c_1(L)/\alpha \cap \{c_1(L)/\beta\}
\]
\[
= - (\mu([pt]), c) \left\{ (\hat{f} \times id)^* c_1(L)/\alpha \cap \{c_1(L)/\beta\} \right\}
\]
We have obtained the first formula in the statement. The proof of the second formula is similar. q.e.d.

With this lemma in mind, let us introduce the following definition.

Definition 3.24. We define
\[
\Psi_{X,f}^{bw,(4)} : A(X) \otimes (H_{odd}(X; \mathbb{Z}) \otimes H_1(B\Gamma; \mathbb{Z})) \to H^*(\text{Pic}(B\Gamma); \mathbb{Q})
\]
by the following formulas. Let \( \beta \in H_1(B\Gamma; \mathbb{Z}) \). Then
\[
\Psi_{X,f}^{bw,(4)}([M_1], \ldots, [M_d]; \alpha, \beta)
\]
\[
= \begin{cases} 
\Psi_{X,odd}([pt], [M_1], \ldots, [M_d]) \left\{ (\hat{f} \times id)^* c_1(L)/\alpha \cap \{c_1(L)/\beta\} \right\} & \text{for } \alpha \in H_1(X; \mathbb{Z}), \\
\Psi_{X,odd}([pt], [M_1], \ldots, [M_d]) \left\{ (\hat{f} \times id)^* c_1(L)^3/\alpha \cap \{c_1(L)/\beta\} \right\} & \text{for } \alpha \in H_3(X; \mathbb{Z}). 
\end{cases}
\]

Remark 3.25. The invariants \( \Psi_{X,f}^{bw,(r)} \) defined in this subsections are homomorphisms and descends to maps on \( H_1(X; \mathbb{Z}) \). See remark 2.9 and remark 3.10

3.4. Applications.

3.4.1. Statements. We will consider connected sums \( \#_m S^1 \times S^3 \), and let \( \pi_1(\#_m S^1 \times S^3) \to \Gamma := \mathbb{Z}^m \) be the homorphism obtained by commuting the fundamental group. By forgetting \( \pi_1(Y) \) factor, we obtain the group homomorphism
\[
f : \pi_1(Y\#(\#_m S^1 \times S^3)) \cong \pi_1(Y) \ast \pi_1(\#_m S^1 \times S^3) \to \Gamma := \mathbb{Z}^m.
\]

Let \( \ell_i = S^1 \times \{pt\} \subset \#_m S^1 \times S^3 \) be the \( i \)-th canonical loop for \( 1 \leq i \leq m \), which consists of a canonical generating set of \( \pi_1(\#_m S^1 \times S^3) \).

Let us introduce the simple type condition for \( \Psi_X \). We say that \( X \) has simple type, if the following equality holds:
\[
\Psi_X([pt], [pt], [M_1], \ldots, [M_d]) = 4\Psi_X([M_1], \ldots, [M_d]).
\]
See definition 1.4 of [23]. Several classes of algebraic surfaces satisfy this property.

By use of the invariant \( \Psi_{\text{tw},(4)}^{X,f} \), we can reproduce both the non-decomposibility (theorem 3.11) and exotic pairs (theorem 3.12) under the additional assumption of simple type:

**Corollary 3.26.** Let \( m \) be an integer with \( m \geq 2 \). Using the invariant \( \Psi_{\text{tw},(4)}^{X,f} \), we can show the following statements:

1. Let \( Y \) be a simply connected, spin, algebraic surface of simple type, with \( b^+ > 1 \). Then \( X = Y \# (\#^m S^1 \times S^3) \) cannot admit any connected sum decomposition as \( X = X_1 \# X_2 \) with \( b^+(X_i) > 0 \).

2. Suppose \( Y_1 \) and \( Y_2 \) is a pair of compact and spin 4-manifolds with \( b^+ > 1 \), which are mutually homeomorphic. Assume moreover \( Y_2 \) has simple type.

If \( \Psi_{Y_1,\text{odd}} \) is trivial, but \( \Psi_{Y_2,\text{odd}} \) is not trivial, so that they consist of an exotic pair, then the pair \( (Y_1 \# (\#^m S^1 \times S^3), Y_2 \# (\#^m S^1 \times S^3)) \) is also exotic.

This is obtained by a parallel argument as Section 3.2, by use of proposition 3.27 and proposition 3.28 below.

3.4.2. **Computation of the invariants.** Assume that all four manifolds \( Y \) or \( X \) are compact and spin with \( b^+ > 1 \).

**Proposition 3.27.** Let \( X = Y \# (\#^m S^1 \times S^3) \). Then for \( f \) as above, we have the equality

\[
\Psi_{\text{tw},(4)}^{X,f}(\[M_1], \ldots, [M_d], [\ell_1], \ldots, [\ell_{m-1}]; [\ell_m], \beta) = -\Psi_{\text{Y,odd}}(pt, [M_1], \ldots, [M_d])\eta_m \cup \{c_1(L)/\beta\},
\]

where \([M_1], \ldots, [M_d] \in H_{\leq 3}(Y; \mathbb{Z})\), and \( \eta_m \) is the canonical generator of the \( m \)-th component of \( H^1(\text{Pic}(B\mathbb{Z}^m); \mathbb{Z}) = \oplus^m H^1(\text{Pic}(B\mathbb{Z}); \mathbb{Z}) \).

**Proof.** Use the equality

\[
(\hat{f} \times \text{id})^*c_1(L)/[\ell_m] = \eta_m,
\]

and follow the discussion of the proof of Proposition 3.13. q.e.d.

**Proposition 3.28.** If \( X = X_1 \# X_2 \) with \( b^+(X_1), b^+(X_2) > 0 \), \( \Psi_{\text{tw},(4)}^{X,f} \) is trivial.

**Proof.** This follows from the vanishing result of the Donaldson invariant \( \Psi_X \). See Proposition 3.14. q.e.d.

3.4.3. **Examples.** Recall \( S_d \) in 3.2.2, and put \( X_{d,m} := S_d \# (\#^m S^1 \times S^3) \) with \( m \geq 2 \). Let \( d \) be even and greater than or equal to 4.

Lemma 3.29 below with proposition 3.27 gives infinitely many exotic smooth structures \( X_{d,m} \) for \( m \geq 2 \) as in section 3.2.

**Lemma 3.29.** \( \Psi_{X_{d,m},f}^{\text{tw},(4)} \) is non-trivial for \( m \geq 2 \).

**Proof.** It is known that \( S_d \) have simple type if \( d \geq 4 \). See lemma 8.9 of [23].
By proposition 3.27 we have

\[ \Psi_{tw,4}^{X_{d,m},f}([pt], h, \ldots, h, [l_1], \ldots, [l_{m-1}]; [l_m], \beta_1) = -\Psi_{S_d,odd}([pt], [pt], h, \ldots, h) \eta_m \cup \eta_1 \]

Here \( \beta_1 \) is the generator of the first component of \( H_1(B\mathbb{Z}^m; \mathbb{Z}) \cong \oplus^m H_1(B\mathbb{Z}; \mathbb{Z}) \), \( h \in H_2(S_d; \mathbb{Z}) \) is the hyperplane class and \( n \) is a large integer of the form

\[ n = 4n' - \frac{3}{2}(1 + b^+(S_d)) \]

with some even integer \( n' \). Note that for such \( n \) we have

\[ \Psi_{S_d,odd}([pt], [pt], h, \ldots, h) = \Psi_{S_d}([pt], [pt], h, \ldots, h) = 4\Psi_{S_d}(h, \ldots, h) \neq 0. \]

Therefore, \( \Psi_{tw,4}^{X_{d,m},f} \) is non-trivial for \( m \geq 2 \) (since \( \eta_m \cup \eta_1 \neq 0 \)). q.e.d.

4. Review of cyclic cohomology

Recall that in the commutative case in Section 3 the twisted Donaldson invariant was introduced by using the cohomology of the classifying space \( H^*(\text{Pic} \Gamma; \mathbb{R}) \). In the case \( \text{Pic} \Gamma \) is homotopy equivalent to the dual torus \( \hat{T}^m \), and hence one can use the de Rham theory over the classifying space.

In the general case of a non-commutative group \( \Gamma \), it would be possible to define \( \text{Pic} \Gamma \), however its structure is quite messy. In fact, its topology can be quite difficult to treat.

There are four steps of non-commutative geometry to overcome this difficulty. Let \( M \) be a finite dimensional smooth manifold.

- Firstly the de Rham cohomology theory is reformulated by a new cohomology theory called cyclic cohomology theory in terms of the algebra \( C^\infty(M) \) of smooth functions on \( M \).
- Secondly the cyclic cohomology theory can be applied also to non-commutative algebras.
- Thirdly the isomorphism \( C(\text{Pic} \mathbb{Z}^m) \cong C^*(\mathbb{Z}^m) \) holds between two \( C^* \)-algebras, where the right hand side is given by completion of the group ring \( \mathbb{C} \mathbb{Z}^m \) under the operator norm. Here \( \mathbb{C} \mathbb{Z}^m \) is identified as a subalgebra of \( B(l^2(\mathbb{Z}^m)) \) by the left regular representation.
- Fourthly the \( C^* \)-algebra \( C^*_\Gamma(\Gamma) \) exists reasonably as the norm completion of the group ring \( \mathbb{C} \Gamma \) in \( B(l^2(\Gamma)) \) for a general group \( \Gamma \).

There is a \(*\)-subalgebra \( C^\infty(\text{Pic} \mathbb{Z}^m) \subset C(\text{Pic} \mathbb{Z}^m) \), and hence if one can find a \(*\)-subalgebra \( \mathcal{A}(\Gamma) \subset C^* \Gamma \) which plays the role of ‘cohomology of smooth algebras’, then one would be able to generalize the construction of the previous section. It will be called a smooth algebra later in this section.

Let \( \mathcal{A} \) be a unital algebra over \( \mathbb{C} \) and \( K_0(\mathcal{A}) \) be the Grothendieck group associated to the stable isomorphism classes of finitely generated projective modules over \( \mathcal{A} \).

Consider a particular case \( \mathcal{A} = C(X) \), where \( X \) is a (reasonable) compact topological space. Let us state a basic correspondence by Swan.
Lemma 4.1. There is a natural isomorphism:

\[ K^0(X) \cong K_0(C(X)) \]

where the left hand side is the topological K-theory.

The isomorphism assigns to a complex vector bundle over \( X \) the set of continuous sections which admits a structure of a finitely generated projective \( C(X) \) module.

The main goal of this section is to introduce theory of cyclic cohomology for a general non-commutative algebra and explain how to pair it with \( K \)-theory of the algebra. We will also present some basic examples. Throughout this section, we refer the comprehensive book by Connes [6].

4.1. Cyclic cohomology. Cyclic cohomology was introduced by Connes. See Section III.1 in [6].

Definition 4.2. Cyclic cohomology \( HC^\bullet(A) \) is the cohomology of the complex \( (C^n_\lambda(A), b) \), where:

\[ C^n_\lambda(A) = \{ \phi : A \otimes \cdots \otimes A \to \mathbb{C} \mid (\ast) \} \]

is the space of \((n+1)\) multi-linear functionals satisfying the cyclic condition

\[ (\ast) \quad \phi(a^1, \ldots, a^n, a^0) = (-1)^n \phi(a^0, \ldots, a^n) \quad a^j \in A, \]

and

\[ b : C^n_\lambda(A) \to C^{n+1}_\lambda(A) \]

is the Hochschild coboundary map given by

\[ (b\phi)(a^0, \ldots, a^{n+1}) = \sum_{j=0}^n \phi(a^0, \ldots, a^j, a^{j+1}, \ldots, a^{n+1}) + (-1)^{n+1} \phi(a^{n+1}, a^0, \ldots, a^n). \]

To recover the de Rham theory for commutative case, one has to pass through stabilization of the cyclic theory.

For two unital algebras \( A_1 \) and \( A_2 \), there is a well defined cup product

\[ \cup : HC^i(A_1) \times HC^j(A_2) \to HC^{i+j}(A_1 \otimes A_2). \]

Let \( A_1 = A_2 = \mathbb{C} \), then \( HC^\bullet(\mathbb{C}) \cong \mathbb{C}[\sigma] \) is a polynomial ring through the cup product with one generator \( \sigma \) of degree 2. For \( A_1 = A, A_2 = \mathbb{C} \), \( HC^\bullet(A) \) is a module over \( HC^\bullet(\mathbb{C}) \).

The periodic cyclic cohomology is defined by

\[ HP^\bullet(A) := \lim_{k \to \infty} HC^{\bullet+2k}(A), \quad \bullet = 0, 1 \]

with respect to the inductive limit of the \( S \)-maps given below

\[ S : HC^n(A) \to HC^{n+2}(A). \]

by multiplying the generator \( \sigma \) of \( HC^2(\mathbb{C}) \) to \( HC^n(A) \) with respect to (4.1).

Example 4.3. (1) Let \( M \) be a compact smooth manifold. Then

\[ HC^k(C^\infty(M)) \cong [\ker d^k \subset \Omega_k(M)] \oplus H_{k-2}(M, \mathbb{C}) \oplus H_{k-4}(M, \mathbb{C}) \oplus \cdots \]
where $\Omega^k(M)$ is the space of $k$-forms and $d^t$ is the de Rham differential. The periodic cyclic cohomology group is isomorphic to the de Rham homologies of $M$ (Section III.2.a [8])

$$HP^0(C^\infty(M)) \simeq H_{\text{even}}(M), \quad HP^1(C^\infty(M)) \simeq H_{\text{odd}}(M).$$

(2) Let $\Gamma$ be a discrete group and $C\Gamma$ be its group ring. There is a canonical map

$$\tau: H^\bullet(\Gamma; \mathbb{C}) \simeq H^\bullet(B\Gamma; \mathbb{C}) \to HC^\bullet(C\Gamma).$$

See page 377 of [9] or [26] for a concrete description.

Let $Z_\Gamma(g) = \{ h \in \Gamma | gh = hg \}$ be the centrilizer of $g$ in $\Gamma$ and put $N_g = Z_\Gamma(g)/\langle g \rangle$.

**Lemma 4.4.** Assume $\Gamma$ is torsion free. Then the isomorphism

$$\tau: H^{\text{even/odd}}(B\Gamma; \mathbb{C}) \simeq HP^{0/1}(C\Gamma)$$

holds, if there is $l_0 > 0$ such that $H^l(BN_g, \mathbb{C})$ vanishes for all $g \neq e$ and all $l \geq l_0$.

So a non commutative counterpart of the group cohomology should be the periodic cyclic cohomology of the group ring.

**Proof.** Denote by $\langle \Gamma \rangle_f$ the set of conjugacy classes of finite order elements in $\Gamma$, and by $\langle \Gamma \rangle_i$ the one with elements of infinite order. Then $HC^\bullet(C\Gamma)$ admits a decomposition (see [5])

$$HC^l(C\Gamma) = \{ \Pi_{g \in \langle \Gamma \rangle_f} [\oplus_{m+n=l} H^m(N_g, \mathbb{C}) \otimes HC^n(\mathbb{C})] \} \oplus \Pi_{g \in \langle \Gamma \rangle_i} H^l(N_g, \mathbb{C}).$$

Because $\Gamma$ is torsion free, so $g \in \langle \Gamma \rangle_f$ if and only if $g$ is the identity $e$. It follows from the equality $H^m(N_e, \mathbb{C}) = H^m(\Gamma, \mathbb{C})$ that (4.6) is reduced to

$$HC^l(C\Gamma) = [\oplus_{l-m \geq 0, \text{even}} H^m(\Gamma, \mathbb{C})] \oplus \Pi_{g \neq e} H^l(N_g, \mathbb{C}).$$

q.e.d.

**Example 4.5.** (1) (4.5) holds if $\Gamma = \mathbb{Z}^k$ is free abelian. This follows from the fact that

$$H^l(B(Z_\Gamma(g)/\langle g \rangle), \mathbb{C}) = H^l(B(\mathbb{Z}^k/\langle g \rangle), \mathbb{C}) = 0$$

for $l > k$.

(2) (4.5) is true when $\Gamma$ is a torsion free Gromov hyperbolic group, such as the fundamental group of a compact hyperbolic manifold. In such case, the centrilizer of an element $g \in \Gamma$ of infinite order contains the cyclic group $\langle g \rangle$ as a subgroup of finite index and then $H^l(N_g, \mathbb{C})$ vanishes.

(3) In general, (4.5) is not true if $\Gamma$ is not torsion free.
4.2. Pairing with $K$-theory for group $C^*$-algebras. Let us quickly review the Connes-Chern character

$$\text{Ch} : K_0(A) \rightarrow HP_0(A)$$

known as the notion of Chern character in the context of noncommutative geometry. This is determined by pairing $K$-theory with cyclic cohomology

$$HC^{2k}(A) \times K_0(A) \rightarrow \mathbb{C}.$$ 

Let $e$ be an idempotent of the matrix algebra $M_q(A)$ which represents an element in $K_0(A)$. Let $\text{Tr}$ be the matrix trace. A $2k$-cyclic cocycle $\phi$ lifts to the linear map on matrix algebras

$$\phi_q : M_q(A) \otimes (2^{k+1}) \rightarrow M_q(C).$$

Then we denote by $\phi^\# \text{Tr}$ the $(2^{k+1})$-linear functional by

$$\langle [\phi], [e] \rangle = 1/2^k (\phi^\# \text{Tr})(e, \ldots, e).$$

Lemma 4.6. The pairing (4.7) is compatible with the $S$-map (4.3), i.e.,

$$\langle [\phi], [e] \rangle = \langle [S\phi], [e] \rangle$$

and thus this leads to a well defined pairing

$$HP^0(A) \times K_0(A) \rightarrow \mathbb{C}.$$  (4.8)

(Section III.3 Proposition 2 [6]. See also [7] page 110 for the odd degree case).

Definition 4.7. The Connes-Chern character map on $K$-theory is the map induced by the pairing in Lemma 4.6

$$\text{Ch} : K_*^*(A) \rightarrow \text{Hom}(HP^*(A), \mathbb{C}) \quad * = 0, 1.$$ 

Identifying the dual theory $HP_*(A)$, the cyclic homology of $A$, with $\text{Hom}(HP^*(A), \mathbb{C})$, under a natural pairing $HP_*(A) \otimes HP^*(A) \rightarrow \mathbb{C}$, (4.7) is equivalent to

$$\text{Ch} : K_*^*(A) \rightarrow HP_*(A) \quad * = 0, 1.$$ 

Denote the restriction

$$\text{Ch}_n : K^*_n(A) \rightarrow \text{Hom}(HC^n(A), \mathbb{C})$$

by composing the right-hand-side with $HC^n(A) \rightarrow HP^*(A)$, given by (1.2), where $n$ and $\bullet$ have the same parity.

For example, the first Chern class $c_1(E) = \text{Ch}_2(E)$ is an element in $\text{Hom}(HC^2(A), \mathbb{C})$ given by the pairing

$$[\tau] \mapsto \langle [E], [\tau] \rangle.$$ 

Let $\Gamma$ be a finitely generated group. We introduce an intermediate algebra which can be regarded as a kind of noncommutative version of the algebra of smooth functions.

The following Lemma is well known, and is used in [9].
Lemma 4.8. Consider an intermediate algebra $\mathbb{C}\Gamma \subset A \subset C_r^*(\Gamma)$. If

1. $A$ is closed under holomorphic functional calculus in $C_r^*(\Gamma)$, and
2. $A$ is dense in $C_r^*(\Gamma)$,

then the isomorphism holds:

\begin{equation}
K_0(C_r^*(\Gamma)) \simeq K_0(A).
\end{equation}

We will call $A$ as a smooth algebra of $\Gamma$, if it satisfies both the above two conditions, and will denote $A = C^\infty(\Gamma)$. Notice that a smooth algebra always exists (say, take $C_0^*(\Gamma)$ itself).

For a general $\Gamma$, a smooth algebra may not be unique. On the other hand a group with the property RD (rapidly decay) has a canonical candidate for $C^\infty(\Gamma)$. For every smooth subalgebra, there is a well defined Connes-Chern character map

\begin{equation}
\text{Ch} : K_*(C_r^*(\Gamma)) \to HP_*(C^\infty(\Gamma)).
\end{equation}

A canonical smooth subalgebra and a geometric description of the Connes-Chern character is obtained by Lott for hyperbolic groups [20].

4.3. Assembly map. Let $\Gamma$ be a finitely generated group. Let us briefly explain the Baum-Connes assembly map

\[ \mu : K_*(B\Gamma) \to K_*(C_r^*(\Gamma)). \]

To understand this map, let us consider the example of a free abelian $\Gamma \cong \mathbb{Z}^m$. Then the assembly map is expressed as $\mu : K_*(T^m) \to K^*(\hat{T}^m)$. An element of the $K$-homology group $K_0(B\mathbb{Z}^m)$ is represented by a triple $(E, F, D)$ where both $E$ and $F$ are complex vector bundles over $T^m$ and $D$ is an elliptic differential operator between their sections. To describe $\mu(E, F, D)$, take an element $\rho \in \hat{T}^m$ which represents a homomorphism $\rho : \mathbb{Z}^m \to S^1$. It gives a flat $U(1)$ bundle on $T^m$, and twists the triplet as $(E_\rho, F_\rho, D_\rho)$. Then the family of indices

\[ \sqcup_{\rho \in \hat{T}^m} \ker D_\rho - \coker D_\rho \]

represents an element in $K^0(\hat{T}^m)$. This construction works only for a commutative $\Gamma$.

Let us reformulate this assignment of $\mu$, replacing $C(\hat{T}^m)$ by $C_*(\mathbb{Z})$. Recall the isomorphism $C_*(\mathbb{Z}^m) \cong C(T^m)$ given by the Gelfand transform. Consider a flat $C^*$-bundle $\gamma := \mathbb{R}^m \times \mathbb{Z}^m C_*(\mathbb{Z}^m)$, and twist the two bundles as $E_\gamma := E \otimes \gamma$ and $F_\gamma := F \otimes \gamma$ so that they are both $C_*(\mathbb{Z}^m)$-module bundles. Since $\gamma$ is flat, $D$ extends to an operator $D_\gamma$ between them. Then both $\ker D_\gamma$ and $\coker D_\gamma$ are finitely generated projective $C_*(\mathbb{Z}^m)$ modules (after stabilization). So their difference $\ker D_\gamma - \coker D_\gamma$ gives rise to an element $K_0(C_*(\mathbb{Z}^m))$. Through the isomorphism $K^0(\hat{T}^m) \cong K_0(C_*(\mathbb{Z}^m))$, these two constructions coincide.

Now the latter construction works for any finitely generated groups $\Gamma$: just replace $\mathbb{R}^m$ by $ET$ and $\mathbb{Z}^m$ by $\Gamma$. This is the Baum-Connes assembly map.

An element in $K_*(B\Gamma)$ is represented by a continuous map $f : M \to B\Gamma$ with a complex vector bundle $E \to B\Gamma$, where $M$ is a compact spin$^c$ manifold. Then we obtain a twisted Dirac operator $D_{f^*E}$ over $S \otimes f^*E$ with the spin$^c$
bundle $S$. The image of the element in $K_s(C_r^*(\Gamma))$ is given by the higher index of $D_T F$ (see Section 4.5).

The Baum-Connes conjecture claims rational isomorphism of the assembly map. It is still open in general, but various classes of discrete groups have been verified to be true. Both the Novikov conjecture and the Gromov-Lawson conjecture follow from rational injectivity of the assembly map, and the Kaplansky conjecture follows from surjectivity of the map.

4.4. Admissibility. The assembly map $\mu$ factors through the index map of $\Gamma$-invariant elliptic operators

$$\mu_\nu : K_*(B\Gamma) \to K_*(C\Gamma \otimes R)$$

i.e., $\mu = j_* \circ \mu_0$ for the inclusion $j : C\Gamma \otimes R \to C^*_r(\Gamma) \otimes K$. Here $R$ is the algebra of smooth operators on $M$ and $K$ consists of compact operators, the $C^*$-algebra closure of $R$. See Section 4.5 or [9].

Recall $\tau_\eta \in HC^*(C\Gamma)$ given by (4.4) for $\eta \in H^*(\Gamma; \mathbb{C})$. Let us say that an element of the group cohomology $\eta \in H^*(\Gamma; \mathbb{C})$ is extendable, if there exists $\tilde{\tau}_\eta \in \text{Hom}(K_*(C^*_r(\Gamma)), \mathbb{C})$ such that $j^* \tilde{\tau}_\eta = \tau_\eta \# \text{Tr}$. This implies that

$$(4.11) \quad \langle \tilde{\tau}_\eta, \mu(D) \rangle = \langle \tau_\eta \# \text{Tr}, \mu_0(D) \rangle$$

for all $[D] \in K_*(B\Gamma)$. See (4.7) for $\tau_\eta \# \text{Tr}$ or [9] on page 377. We say that a group $\Gamma$ is extendable, if any element $\eta \in H^*(\Gamma; \mathbb{C})$ is extendable.

Let $C^\infty(\Gamma)$ be a smooth algebra. Recall that the inclusion $i : C\Gamma \to C^\infty(\Gamma)$ induces a map $i^* : HC^*(C^\infty(\Gamma)) \to HC^*(C\Gamma)$. Let us introduce a class of discrete groups:

**Definition 4.9.** A group $\Gamma$ is admissible, if it admits a smooth algebra $C^\infty(\Gamma)$ such that there exists a map $\nu : H^*(\Gamma; \mathbb{C}) \to HC^*(C^\infty(\Gamma))$ such that $i^* \nu(\eta) = \tau_\eta$ for all $\eta \in H^*(\Gamma; \mathbb{C})$.

**Example 4.10.** (1) $\Gamma$ is admissible, if it satisfies both polynomial cohomology and rapid decay property in the sense of [9]. It is known that a finitely generated hyperbolic group with respect to some word metric satisfies the two properties.

(2) $\Gamma$ is admissible, if it is isomorphic to a free abelian group or a torsion free hyperbolic group. In fact, a canonical smooth algebra $C^\infty(\Gamma)$ exists for both classes of groups. By Lemma 4.4 $\tau$ is an isomorphism, i.e., $H^*(\Gamma; \mathbb{C}) \simeq HP^*(C\Gamma)$. Thus, the claim follows because of the existence of $\nu^* : HP^*(C\Gamma) \to HP^*(C^\infty(\Gamma))$ such that $i^* \nu^* = 1$ which is a result of surjectivity of $i^*$. Note that $HP^*(C\Gamma) \simeq HP^*(C^\infty(\Gamma))$ for free abelian group and that $i^* : HP^*(C^\infty(\Gamma)) \to HP^*(C\Gamma)$ is surjective when $\Gamma$ is hyperbolic [17].

**Remark 4.11.** (1) If $\Gamma$ is admissible, the map $\nu$ gives rise to a well defined pairing

$$H^*(\Gamma; \mathbb{C}) \times HP^*(C^\infty(\Gamma)) \to \mathbb{C}.$$ 

(2) If moreover $HP^*(C^\infty(\Gamma))$ is finite dimensional, then there is a well defined pairing

$$H^*(\Gamma; \mathbb{C}) \otimes H^*(\Gamma; \mathbb{C}) \times HP^*(C^\infty(\Gamma) \otimes C^\infty(\Gamma)) \to \mathbb{C}.$$ 

See the proof of Lemma 4.16 for Künneth formula for the periodic cyclic cohomology.
Recall that the Connes-Chern character \([4.10]\) determines a dual Connes-Chern character
\[ (4.12) \]
\[
\text{Ch}^f : HP^*(C^\infty(\Gamma)) \to \text{Hom}(K_*(C^*_\Gamma(\Gamma)), \mathbb{C}) \quad a \mapsto (x \mapsto \langle \text{Ch}(x), a \rangle).
\]

**Lemma 4.12.** If \(\Gamma\) is admissible, then \(\text{Ch}^f\) is a canonical map.

**Proof.** Suppose \(\Gamma\) is admissible, i.e., \(i^*\nu(\eta) = \tau_\eta\). Similar to \([4.12]\), there is a dual Connes-Chern character \(\text{Ch}^f : HC^*(\mathbb{C}) \to \text{Hom}(K_*(C^*_\Gamma(\Gamma)), \mathbb{C})\) (see \([9]\)). Denoting \(\tilde{\tau}_\eta := \text{Ch}^f(i^*(\nu(\eta)) \in \text{Hom}(K_*(C^*_\Gamma(\Gamma)), \mathbb{C})\), we have
\[
j^*(\tilde{\tau}_\eta) = j^*(\text{Ch}^f(i^*(\nu(\eta)))) = \text{Ch}^f(i^*(\nu(\eta))) = \text{Ch}^f(\tau_\eta) = \tau_\eta \# \text{Tr}.
\]
The second equality follows from the functoriality of \(\text{Ch}^f\). q.e.d.

Suppose the classifying space of \(\Gamma\) is homotopy equivalent to a finite CW complex, and consider the dualized Baum-Connes assembly map
\[
\mu^f : \text{Hom}(K_*(C^*_\Gamma(\Gamma)), \mathbb{C}) \to K^*(BG)
\]
given by
\[
\langle \mu^f(\alpha), \beta \rangle := \langle \alpha, \mu(\beta) \rangle \quad \beta \in K_*(BG).
\]
This map is directly constructed in \([29]\). See also \([10]\). Together with the dual Connes-Chern character \(\text{Ch}^f\) and ordinary Chern character \(\text{ch}\) we obtain a canonical map
\[ (4.13) \]
\[
HP^*(C^\infty(\Gamma)) \xrightarrow{\text{Ch}^f} \text{Hom}(K_*(C^*_\Gamma(\Gamma)), \mathbb{C}) \xrightarrow{\mu^f} K^*(BG) \xrightarrow{\text{ch}} H^*(\Gamma; \mathbb{C}).
\]
Here, the last map, the Chern character \(\text{ch}\) for \(K\)-homology, is defined so that the pairing of \(K\)-theory and \(K\)-homology is compatible with the pairing of cohomology and homology after taking Chern character (see \([7]\)).

**Proposition 4.13.** If \(\Gamma\) is admissible, then the canonical map \(HP^*(C^\infty(\Gamma)) \to H^*(\Gamma; \mathbb{C})\) given by \((4.13)\) is surjective, mapping \(\nu(\eta)\) to \(\eta\).

**Proof.** If \(\Gamma\) is admissible, then \(\nu(\eta)\) exists for all \(\eta \in H^*(\Gamma; \mathbb{C})\). Then we need only to show that \(\text{ch} \circ \mu^f \circ \text{Ch}^f(\nu(\eta)) = \eta\). Every element in \(K_*(BG)\) is represented by a \(f : M \to BG\) with \(E \to BG\) and a spin Dirac operator \(D\) on \(M\). We denote this element by \(f_*[D_E]\). It is thus sufficient to show
\[
\langle \text{ch} \circ \mu^f \circ \text{Ch}^f(\nu(\eta)), \text{ch}(f_*[D_E]) \rangle = \langle \eta, \text{ch}(f_*[D_E]) \rangle.
\]
From the proof of Lemma \(4.12\) one may choose \(\tau_\eta = \text{Ch}^f(\nu(\eta))\) so that \(j^*\tilde{\tau}_\eta = \tau_\eta \# \text{Tr}\). Thus
\[
\langle \text{ch} \circ \mu^f \circ \text{Ch}^f(\nu(\eta)), \text{ch}(f_*[D_E]) \rangle = \langle \text{ch}(\mu^f(\tau_\eta)), \text{ch}(f_*[D_E]) \rangle.
\]
By definition of \(\text{ch}\) and \(\mu^f\) and then the Connes-Moscovici’s index theorem, we have
\[
\langle \text{ch}(\mu^f(\tau_\eta)), \text{ch}(f_*[D_E]) \rangle = \langle \mu^f(\tau_\eta), f_*[D_E] \rangle = \langle \tau_\eta, \mu(f_*[D_E]) \rangle = \int_M \hat{A}(M) \text{ch}(E) \wedge f^*\eta.
\]
On the other hand by definition of \(\text{ch}\), \(\text{ch}(D)\) is the de Rham current \(f_*\left( f_M \hat{A}(M) \wedge \right)\) (see Theorem \(4.20\)), and then
\[
\langle \eta, \text{ch}(f_*[D_E]) \rangle = \langle f^*\eta, \text{ch}(D_E) \rangle = \int_M \hat{A}(M) \text{ch}(E) \wedge f^*\eta.
\]
The proposition is then proved. q.e.d.
Corollary 4.14. Suppose the classifying space of $\Gamma$ is homotopy equivalent to a finite CW complex. Then $\Gamma$ being extendable implies that the assembly map $\mu : K_*(B\Gamma) \to K_*(C^*_r(\Gamma))$ is rationally injective.

Proof. From the previous proposition, the composition $\mu^t \circ \text{ch} : \text{Hom}(K_*(C^*_r(\Gamma)), \mathbb{C}) \to H^*(\Gamma, \mathbb{C})$ maps $\text{Ch}^t(\nu(\eta))$ to $\eta$, hence surjective. The corollary then follows observing that rational injectivity of $\mu$ is equivalent to rational surjectivity of $\mu^t$ and that the Chern character $K^*(B\Gamma) \to H^*(\Gamma; \mathbb{C})$ is rationally isomorphic. q.e.d.

Remark 4.15. Either extendability or admissibility of $\Gamma$ implies the Novikov conjecture for the group. The rational injectivity of the assembly map is called the \textit{strong Novikov conjecture}, which is a sufficient condition to induce both Novikov conjecture (homotopy invariance of higher signatures) and Gromov-Lawson conjecture, where the latter claims that no positive scalar curvature metric can be equipped with on a compact $K(\Gamma, 1)$ manifold.

The following technical Lemma gives a sufficient condition that the canonical map \ref{lem:4.13} (with tensors) is an isomorphism, which is used in Definition \ref{def:5.7}.

Lemma 4.16. Suppose that the classifying space of $\Gamma$ is homotopy equivalent to a finite CW complex, $\Gamma$ is admissible, and $H^p(C^\infty(\Gamma))$ is finite dimensional.

Then there is a surjective map

$$H^p(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B)) \to \bigoplus_{i+j+k=l(2)} H^i(\Gamma) \otimes H^j(\Gamma) \otimes H_k(B).$$

If moreover $\Gamma$ satisfies the Baum-Connes conjecture and Connes-Chern character \ref{eq:4.10} is an isomorphism, then the map is an isomorphism.

Here, the tensor product on the left hand side is the projective tensor product of Frechét algebras (see \cite{27} for example). When $\Gamma$ is abelian, $C^\infty(\Gamma)$ and $C^\infty(B)$ are nuclear, the tensor product is uniquely defined.

For the reduced group $C^*$-algebras, we will use the minimal tensor product $C^*_r(\Gamma) \otimes_{min} C^*_r(\Gamma)$ and just denote as $C^*_r(\Gamma) \otimes C^*_r(\Gamma)$.

Example 4.17. Free abelian groups satisfies the assumptions of Lemma \ref{lem:4.16}

To conclude the subsection, we present a proof of Lemma \ref{lem:4.16}.

Proof of Lemma \ref{lem:4.16}. First of all, we have an isomorphism

\begin{equation}
H^p(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B)) \simeq \\
\bigoplus_{i+j+k=l(2)} H^p(C^\infty(\Gamma)) \otimes H^j(\Gamma) \otimes H^k(B)
\end{equation}

following from the Künneth theorem. In fact, the cup product \ref{eq:4.11} on the cyclic cohomology induces the one on periodic cyclic cohomology

$$\bigoplus_{i+j=k} H^p(A_1) \otimes H^j(\mathcal{A}_2) \to H^k(\mathcal{A}_1 \otimes \mathcal{A}_2)$$

It is known to be isomorphic when one of $\mathcal{A}_i$ is countably generated and $H^p(\mathcal{A}_i)$ is finite dimensional.

The algebra $C^\infty(\Gamma)$ is always countably generated when $\Gamma$ is a countable discrete group. $C^\infty(B)$ is also countably generated. $H^p(C^\infty(B))$ is finite.
dimensional when \( B \) is compact (see subsection 4.1). Together with the assumption that \( HP^\ast(C^\infty(\Gamma)) \) is finite dimensional, we obtain the isomorphism \( \mathbf{[4.13]} \).

In view of \( HP^\ast(C^\infty(B)) \cong H_4(B) \) (see Example \( \mathbf{[4.3]} \), we only need a surjective map from \( HP^\ast(C^\infty(\Gamma)) \) to \( H^\ast(\Gamma; \mathbb{C}) \), guaranteed by Lemma \( \mathbf{[4.13]} \) the composition of maps

\[
(4.15) \quad HP^\ast(C^\infty(\Gamma)) \xrightarrow{\text{Ch}^\Gamma} \text{Hom}(K_\ast(C_r^\ast(\Gamma)), \mathbb{C}) \xrightarrow{\mu} K^\ast(B\Gamma) \xrightarrow{\text{ch}} H^\ast(\Gamma; \mathbb{C})
\]
is a surjection.

Together with \( \mathbf{[4.14]} \) there exist a surjective map as required.

If \( \Gamma \) satisfies the Baum-Connes conjecture, then \( \mu \) is rationally isomorphic and so is \( \mu^\prime \). The first and third maps in \( \mathbf{[4.15]} \) are both isomorphic over \( \mathbb{C} \). Hence, the above surjective map is actually an isomorphism. q.e.d.

4.5. Higher indices. Let \( \Gamma \) be a discrete group where \( B\Gamma \) is its classifying space. We shall review the cohomological formula of the higher index of a \( \Gamma \)-invariant twisted Dirac operator by Connes and Moscovici \( \mathbf{[9]} \).

Let \( M \) be a closed Riemannian manifold and \( \phi : M \to B\Gamma \) a continuous map. Let \( \tilde{M}^\phi \to M \) be the \( \Gamma \)-principal bundle given by the pull-back \( \phi^\ast \pi \) of the universal covering \( \pi : E \Gamma \to B\Gamma \). Denote by \( D \) an elliptic operator over \( E \to M \), and by \( \tilde{D}^\phi \) its lift over \( \tilde{M}^\phi \) as a \( \Gamma \)-invariant elliptic operator.

Let \( C_r^\ast(\Gamma) \) be the reduced group \( C^\ast \)-algebra which is given by the operator norm completion of the group ring \( C\Gamma \) by the regular representation on \( L^2(\Gamma) \). The quotient of \( \tilde{M}^\phi \times C_r^\ast(\Gamma) \) by the diagonal action of \( \Gamma \) gives a flat \( C_r^\ast(\Gamma) \)-bundle \( \gamma \) on \( M \). Denote by \( D_\Gamma^\phi \) the twisted operator obtained by twisting \( D \) with the flat bundle \( \gamma \). Then \( D_\Gamma^\phi \) is a \( C_r^\ast(\Gamma) \)-Fredholm operator over \( E \otimes \gamma \).

The higher index of \( \tilde{D}^\phi \) is defined as the index \( \text{Ind } D_\Gamma^\phi \) of the \( C_r^\ast(\Gamma) \)-Fredholm operator \( D_\Gamma^\phi \)

\[
\text{Ind } \tilde{D}^\phi := \text{Ker } D_\Gamma^\phi - \text{Coker } D_\Gamma^\phi \in K_0(C_r^\ast(\Gamma))
\]
where \( \text{Ker } D_\Gamma^\phi \) and \( \text{Coker } D_\Gamma^\phi \) are both regarded as finitely generated projective \( C_r^\ast(\Gamma) \)-modules after compact perturbations. See \( \mathbf{[20]} \).

By choosing a suitable parametrix of \( \tilde{D}^\phi \), Connes and Moscovici \( \mathbf{[9]} \) verified that the higher index of \( \tilde{D}^\phi \) comes from an element in the \( K \)-theory of a smaller algebra

\[
\text{Ind } \tilde{D}^\phi \in K_0(C\Gamma \otimes \mathcal{R})
\]
where \( \mathcal{R} \) is the algebra of smoothing operators on \( M \). Recall that \( \mathcal{R} \) is dense in the \( C^\ast \)-algebra of compact operators \( \mathcal{K} \). The higher index coincides with the image of this element under composition of the maps

\[
K_0(C\Gamma \otimes \mathcal{R}) \to K_0(C_r^\ast(\Gamma) \otimes \mathcal{K}) \simeq K_0(C_r^\ast(\Gamma))
\]
induced by the inclusion \( j : C\Gamma \otimes \mathcal{R} \to C_r^\ast(\Gamma) \otimes \mathcal{K} \). That is, \( j_\ast(\text{Ind } \tilde{D}^\phi) = \text{Ind } \tilde{D}^\phi = \text{Ind } D_\Gamma^\phi \). See Lemma 6.1 of \( \mathbf{[9]} \). So we shall also call these elements the higher index.

Remark 4.18. In Section \( \mathbf{[5]} \) we have to use the \( C_r^\ast(\Gamma) \)-Fredholm index of \( D_\Gamma^\phi \) in \( K_0(C_r^\ast(\Gamma)) \) given by the higher index of \( \tilde{D}^\phi \), rather than the element in
Proof. For every $H \in \text{Hom}(\Gamma; \mathbb{C})$, which corresponds to an element $\eta \in H^0(\Gamma, \mathbb{C})$, through the map $\tau$ in (4.14). By composition with the operator trace it gives a cyclic cocycle

$$\tau_\eta \# \text{Tr} \in HC^m(\mathbb{C} \otimes \mathcal{R}).$$

**Theorem 4.19** ([9], see also [26]). Let $\phi : M \to B\Gamma$ be a continuous map. Let $D_E$ be a twisted Dirac operator over $M$ and $\tilde{D}_E^\phi$ be its lift to the $\Gamma$-principal bundle $\tilde{M}^\phi \to M$.

Then the image of the higher index $\text{Ind} \tilde{D}_E^\phi \in K_0(\mathbb{C} \otimes \mathcal{R})$ by the Connes-Chern character admits the cohomological formula

$$\langle \text{Ch}(\text{Ind} \tilde{D}_E^\phi), \tau_\eta \# \text{Tr} \rangle = c \int_M \tilde{A}(M) \wedge \text{ch}(E) \wedge \phi^* \eta$$

which is an element in $\text{Hom}(HP^0(\mathbb{C} \otimes \mathcal{R}), \mathbb{C})$, where $c$ is some normalizing constant.

In particular the first Chern class $c_1(\text{Ind} \tilde{D}_E^\phi)$ of the higher index is described as a homomorphism for $\eta \in H^2(\Gamma, \mathbb{C})$

$$HC^2(\mathbb{C} \otimes \mathcal{R}) \to \mathbb{C}, \quad \tau_\eta \# \text{Tr} \mapsto c \int_M \tilde{A}(M) \wedge \text{ch}(E) \wedge \phi^* \eta.$$

From analytic view point, it is important to find the cohomological formula of the Connes-Chern character of the higher indices $\text{Ind} D_{E}^\phi$ of $C^*_r(\Gamma)$-Fredholm operators in $K_0(C^*_r(\Gamma))$. For this, the cyclic cocycle $\tau_\eta \in HC^*(\mathbb{C} \Gamma)$ should be extended to a map $\tilde{\tau}_\eta : K_0(C^*_r(\Gamma)) \to \mathbb{C}$ such that $j^* \tilde{\tau}_\eta = \tau_\eta \# \text{Tr}$ for every group cocycle $\eta \in H^*(\Gamma; \mathbb{C})$. Connes-Moscovici devised a sufficient condition on $\Gamma$ for the extendability, namely, polynomial cohomology and rapid decay (Proposition 6.3 of [9]), and in our setting this is implied by $\Gamma$ being admissible (Lemma 4.12).

**Proposition 4.20** ([9]). Suppose that $\Gamma$ is admissible so that $\tau_\eta \in HC^*(\mathbb{C} \Gamma)$ gives rise to a map $\tilde{\tau}_\eta : K_0(C^*_r(\Gamma)) \to \mathbb{C}$.

Then the cohomological formula holds:

$$\langle \text{Ch}(\text{Ind} D_{E,\Gamma}^\phi), \tilde{\tau}_\eta \rangle = c \int_M \tilde{A}(M) \wedge \text{ch}(E) \wedge \phi^* \eta.$$  \hspace{1cm} (4.16)

**Proposition 4.21.** Assume that $\Gamma$ is admissible. Let $M$ be a closed manifold and $\phi : M \to B\Gamma$ a continuous map. Let $D_E$ be a twisted Dirac operator over $M$, and $\tilde{M}^\phi \to M$ be the principal $\Gamma$-bundle pulled back from $\tilde{E}\Gamma \to B\Gamma$ by $\phi$. Let $D_{E,\Gamma}^\phi$ be the operator $D_E$ twisted by the bundle $\gamma = \tilde{M}^\phi \times_\Gamma C^*_r(\Gamma)$.

Then the Connes-Chern character of the $C^*_r(\Gamma)$-Fredholm index of $D_{E,\Gamma}^\phi$ in $K_0(C^*_r(\Gamma))$ is completely determined by the cohomological formula (4.10).

**Proof.** For every $y \in \text{Hom}(K_*(C^*_r(\Gamma)); \mathbb{C})$, let us put $\eta := \text{ch}(\mu^!(y)) \in H^*(\Gamma; \mathbb{C})$. Then the equality

$$\langle \mu(D), \tilde{\tau}_\eta \rangle = \langle \mu(D), y \rangle$$  \hspace{1cm} (4.17)
holds, because both sides are equal to $\langle \text{ch}(D), \eta \rangle$ by the proof of Lemma ??. Note that the equality $\eta = \text{ch}(\mu^t(\tilde{\tau}_\eta))$ also holds.

By definition, the equality holds:

$$j_* \text{Ind} \tilde{D}_{E, \Gamma} = \text{Ind} D^\phi_{E, \Gamma}.$$ 

Then we have

$$\langle \text{Ind} D^\phi_{E, \Gamma}, y \rangle = \langle \text{Ind} \tilde{D}_{E, \Gamma}, \tilde{\tau}_\eta \rangle = \langle \text{Ind} \tilde{D}_{E, \Gamma}, \tau_\eta \# \text{Tr} \rangle = c \int_M \tilde{A}(M) \wedge \text{Ch}(E) \wedge \phi^*[\text{ch}(\mu^t(y))].$$

The first equality follows from (4.17); the second from the $\Gamma$ being admissible; the third is Connes-Moscovici’s index formula. Therefore, $\text{Ch}(\text{Ind} D^\phi_{E, \Gamma})$ is completely determined by the cohomological formula. q.e.d.

5. **Twisted Donaldson’s Invariant for non-commutative case**

Throughout section 5, we always assume that all four manifolds $Y$ or $X$ are compact and spin with $b^+ > 1$, without mention.

Let $E \to X$ be an $SU(2)$ vector bundle and $\Gamma$ a discrete group. Fix a homomorphism $f : \pi_1(X) = \pi_1(\hat{X}) \to \Gamma$ which induces a continuous map $\hat{f} : \hat{X} \to B\Gamma$. In this section, we will introduce the twisted $\mu$-map

$$\mu^t_{\hat{f}} : \Omega^\text{Spin}_*(X) \otimes \Omega^\text{Spin}_*(B\Gamma) \to HP_0(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B))$$

where $\Omega^\text{Spin}_*(B\Gamma)$ is the spin bordism group, and $B$ runs over compact submanifolds in $\mathcal{B}^*(\hat{E})$. Let $A^\ast(X)$ be as in (1.3). Then we construct a twisted Donaldson’s invariant

$$\Psi^{\text{tw},(r)}_{X,f} : A^\ast(X) \times (\Omega^\text{Spin}_*(X) \otimes \Omega^\text{Spin}_*(B\Gamma)) \to HP_*(C^\infty(\Gamma) \otimes C^\infty(\Gamma))$$

for $r = 1, 2$ when $\Gamma$ is not necessarily abelian, in terms of non-commutative geometry.

**Remark** 5.1. Our formulation of the twisted Donaldson invariant requires existence of $C^\infty(\Gamma)$ only, however we need to assume that $\Gamma$ is admissible, when we compute the index formula on the twisted $\mu$ map, which is necessary to check well definedness of the twisted $\mu$ map.

The isomorphism $H^\ast(\Gamma; \mathbb{C}) \cong HP^\ast(C^\infty(\Gamma))$ holds, when $\Gamma$ satisfies the Baum-Connes conjecture with isomorphic Chern character (see lemma 4.16), in particular, when $\Gamma \cong \mathbb{Z}^m$ is free abelian. The above map $\Psi^{\text{tw},(r)}_{X,f}$ extends the twisted Donaldson map $(\Psi^{\text{tw},(r)}_{X,f})_{ab}$ in section 3 as

$$A(X) \otimes H_*(X; \mathbb{Z}) \otimes H_*(B\Gamma; \mathbb{Z}) \xrightarrow{(\Psi^{\text{tw},(r)}_{X,f})_{ab}} H_*(\Gamma; \mathbb{Q})$$

and

$$A(X) \otimes H_*(X; \mathbb{Z}) \otimes \Omega^\text{Spin}(B\Gamma) \xrightarrow{\Psi^{\text{tw},(r)}_{X,f}} H_*(\Gamma; \mathbb{C}) \otimes H_*(\Gamma; \mathbb{C})$$
where the right vertical arrow is given by the diagonal embedding.

5.1. **Parametrized higher indices.** Let us take an element $\alpha \in \Omega^2_S(X)$ which is realized by a map $i : M \to X$, and another element $\beta \in \Omega^S(B\Gamma)$ by $j : N \to B\Gamma$.

Assume the product spin manifold $M \times N$ has even dimension, and denote by $S = S^+ \oplus S^-$ the spinor bundle equipped with the spin connection $\nabla^S$ on $M \times N$. Then we have the associated Dirac operator $D^\pm : \Gamma(S^\pm) \to \Gamma(S^\mp)$ over $M \times N$. Notice that $D$ is the operator on the external tensor product of the spinors $S_M \boxtimes S_N$, given by the equality $D = D_M \boxtimes 1 + 1 \boxtimes D_N$.

Take an $SU(2)$-vector bundle $E$ on $X$ with $c_2(E)$ odd. Recall that in order to avoid difficulty caused by reducible flat connections, we use the $U(2)$-vector bundle $\tilde{E}$ on the blow-up $\tilde{X} = X \# \mathbb{CP}^2$. It satisfies $c_1(\tilde{E}) = e$ and $c_2(\tilde{E}) = c_2(E)$, where $e$ is the generator of $H^2(\mathbb{CP}^2; \mathbb{Z}) \subset H^2(\tilde{X}; \mathbb{Z})$.

Let $B$ be a compact submanifold in $\mathcal{B}^*(\tilde{E})$, and take an element $[A] \in B$. The restriction $A|_M$ gives the Dirac operator $D_A$ twisted with $D_M$ over $M$, and hence it extends to the Dirac operator $\mathbb{D}_A = D_A \boxtimes 1 + 1 \boxtimes D_N$ over $M \times N$.

Let us also restrict the universal bundle $\tilde{E}$ to $\tilde{X} \times B$. Then $\mathbb{D}_A$ is regarded as the Dirac operator on $([\tilde{E}]_{M\times\{A\}} \otimes S_M) \boxtimes S_N$.

Denote the $C^*_r(\Gamma)$-bundle over $B\Gamma$ by
\[
\gamma : = E\Gamma \times_{\Gamma} C^*_r(\Gamma)
\]
equipped with a flat connection $\nabla$. Let $f : \tilde{X} \to B\Gamma$ be the continuous map induced by $f$. Then we consider the pull-back bundle
\[
([\tilde{E}]_{M\times\{A\}} \otimes (f \circ i)^*\gamma) \boxtimes j^*\gamma \to M \times N.
\]
The set of $L^2$-sections of this bundle forms a $C^*_r(\Gamma) \otimes C^*_r(\Gamma)$ module.

The restriction $A|_M$ together with the flat connection gives the pull-back connection
\[
(A|_M \otimes 1 + 1 \otimes (f \circ i)^*\nabla) \boxtimes 1 + 1 \boxtimes j^*\nabla.
\]

Twist the Dirac operator $D$ with the connection over $S \otimes ([\tilde{E}]_{M\times\{A\}} \otimes (f \circ i)^*\gamma) \boxtimes j^*\gamma$, and denote it by $\tilde{D}_A$. It is a $(C^*_r(\Gamma) \otimes C^*_r(\Gamma))$-Fredholm operator on $M \times N$ with the higher index (see Section 4.3)
\[
\text{Ind } \tilde{D}_A = [\ker \tilde{D}_A^+] - [\ker \tilde{D}_A^-] \in K_0(C^*_r(\Gamma) \otimes C^*_r(\Gamma)).
\]

**Remark 5.2.** In the notation of Section 4, $\tilde{D}_A$ should have been denoted $D_{A,T \times \Gamma}^\phi$ where $\phi$ is the continuous map $(f \circ i, j) : M \times N \to B(\Gamma \times \Gamma)$.

Now consider a family of Dirac operators
\[
\mathbb{D} : = \{\tilde{D}_A\}_{A \in B}
\]
over $M \times N$ parametrised by $B$, acting on sections of the $(C^*_r(\Gamma) \otimes C^*_r(\Gamma))$-bundle
\[
S \otimes ([\tilde{E}]_{M \times B} \boxtimes (f \circ i)^*\gamma \boxtimes j^*\gamma) \to M \times B \times N.
\]
Recall Lemma 4.1 and that the classical Atiyah-Singer index for the family.
\[
\text{ind}\{D_A\}_{A \in B} = \{[\ker D_A^+] - [\ker D_A^-]\}_{A \in B} \in K_0(B) = K_0(C(B))
\]
takes its value in $K$ cohomology of $B$, determined by the Fredholm property of each $D_A$.

Replacing $|\ker D_A^+| - |\ker D_A^-|$ by the higher index of $\tilde{D}_A$, we obtain the family of higher indices

$$\text{Ind}_B \mathbb{D} = \{\text{Ind} \tilde{D}_A\}_{A \in B} \in K_0(C(B, C_r^*(\Gamma) \otimes C_r^*(\Gamma))).$$

The relevant $C^*$ algebra in $K$-theory is

$$C(B, C_r^*(\Gamma) \otimes C_r^*(\Gamma)) \cong C(B) \otimes C_r^*(\Gamma) \otimes C_r^*(\Gamma)$$

which consists of the set of continuous maps with coefficient in $C_r^*(\Gamma) \otimes C_r^*(\Gamma)$.

$\text{Ind}_B \mathbb{D}$ is compatible with restrictions in $K$-theory, i.e.,

$$\text{Ind}_{B'} \mathbb{D}|_B = \{\text{Ind} \tilde{D}_A\}_{A \in B} = \text{Ind}_B \mathbb{D}$$

where $B \subset B'$.

**Remark 5.3.** There is a local formula of the higher index as below

**Lemma 5.4.** The higher index of $\tilde{D}_A$ is computed by

$$\text{Ind} \tilde{D}_A := \left[ \begin{array}{cc} S_2 & S_0(1 + S_0)Q \\ S_1D_A & 1 - S_1^2 \end{array} \right] - \left[ \begin{array}{cc} 0 & 0 \\ 0 & 1 \end{array} \right] \in K_0(C_r^*(\Gamma) \otimes C_r^*(\Gamma)),$$

where $Q$ is a parametr of $\tilde{D}_A$ where

$$S_0 := 1 - Q\tilde{D}_A, \quad S_1 := 1 - \tilde{D}_AQ$$

are compact operators in the $C_r^*(\Gamma) \otimes C_r^*(\Gamma)$-module.

When $D_A$ depends continuously on $A$, then the operators $\tilde{D}_A$, $Q$ and $S_i$ also depend continuously on $A$. So the family of higher indices gives an element in $K_0(C(B, C_r^*(\Gamma) \otimes C_r^*(\Gamma)))$.

### 5.2. Twisted $\mu$-map.

The Connes-Chern character in Definition 4.7 with Lemma 4.8 give rise to the map

$$\text{Ch} : K_0(C(B, C_r^*(\Gamma) \otimes C_r^*(\Gamma))) \cong K_0(C(B, C^\infty(\Gamma) \otimes C^\infty(\Gamma)))$$

$$\to HP_0(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B))$$

where $HP_0(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B))$ is identified with $\text{Hom}(HP^0(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B)), \mathbb{C})$. Note that holomorphic calculus being closed under project tensor product is not verified. However, assuming Kunneth formula for $K$-theory, for instance, the conditions for Lemma 4.16 we always have the above isomorphism.

**Definition 5.5.** Let us fix a smooth algebra $C^\infty(\Gamma)$. The twisted $\mu$-map

$$\mu^iw : \Omega^2_{\text{spin}}(X) \otimes \Omega^2_{\text{spin}}(B\Gamma) \to \lim_{B} HP_0(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B))$$

is defined for every compact $B$ in $\mathcal{B}^*(\mathcal{E})$ by the Connes-Chern character of the higher index of the family of twisted Dirac operators $\mathbb{D} = \{\tilde{D}_A\}_{A \in B}$

$$\mu^iw(\alpha, \beta) := \{\text{Ch(Ind}_B \mathbb{D)}\}_{B}.$$
In particular \( \mu^\mu_1(\alpha, \beta) \) is independent of choices of \( i : M \to X \) of the class \( \alpha \) of \( \Omega^{\text{Spin}}_*(X) \), choice of \( j : N \to B\Gamma \) of the class \( \beta \) of \( \Omega^{\text{Spin}}_*(B\Gamma) \) and the choice of spin structure on \( M \times N \).

Assume that \( \Gamma \) is admissible, and \( HP^*(C^\infty(\Gamma)) \) is finite dimensional. In view of Remark 4.11 we have the pairing

\[
\bigoplus_{i+j+k=l(2)} H^i(\Gamma) \otimes H^j(\Gamma) \otimes H_k(B) \times HP_1(C^\infty(\Gamma) \otimes C^\infty(\Gamma) \otimes C^\infty(B)) \to \mathbb{C}
\]

given by

\[
([\eta], [\xi], [C], [E]) \mapsto \langle \text{Tr} \#(\tau_\eta \cup \tau_\xi \cup \tau_C), [E] \rangle.
\]

Later we shall use this pairing to evaluate the twisted \( \mu \)-map.

Recall that an element \( \beta \in \Omega^{\text{Spin}}_*(B\Gamma) \) is given by a map \( j : N \to B\Gamma \). Realize an element \( \alpha \in \Omega^{\text{Spin}}_*(X) \) by \( i : M \to X \). Let \( \hat{\mathcal{E}} \to \hat{X} \times B \) be the universal bundle.

The twisted \( \mu \) map admits the cohomological formula.

**Theorem 5.6.** Assume that \( \Gamma \) is admissible, and \( HP^*(C^\infty(\Gamma)) \) is finite dimensional. Let us take elements \( [\eta] \in H^i(\Gamma; \mathbb{C}), [\xi] \in H^j(\Gamma; \mathbb{C}) \) and \( [C] \in H_k(B) \).

Under the pairing \((5.4)\) the twisted \( \mu \)-map \((5.3)\) is determined by the following cohomological formula

\[
\langle \eta \otimes \xi \otimes C, \mu^\mu_1(\alpha, \beta) \rangle = \langle (i \times \text{id})^* \text{ch}(\hat{\mathcal{E}}) \wedge f^*\eta, [M \times C] \rangle \langle \hat{A}(N) \wedge j^*\xi, [N] \rangle \in \mathbb{C}
\]

where \( f : \hat{X} \to B\Gamma \) is the continuous map depending on \( f \).

**Proof.** Observe that the wedge product is compatible with the cup product under \( \tau \)

\[
H^{i+j}(B\Gamma \times B\Gamma) \to HP^{i+j}(C\Gamma \otimes C\Gamma)
\]

\[
[p_1^*\eta \wedge p_2^*\xi] \mapsto [\tau_\eta \cup \tau_\xi].
\]

Because \( \Gamma \) is admissible, there exist \( \tau_\eta, \tau_\xi \in \text{Hom}(K_*(C^*_\Gamma), \mathbb{C}) \) such that

\[
\langle \mu(D), \tau_\eta \cup \tau_\xi \rangle = \langle \mu_0(D), (\tau_\eta \cup \tau_\xi)\# \text{Tr} \rangle.
\]

In our context, \( \mu(D) = \text{Ind} \tilde{D}_A \) and the right hand side is calculated by Connes-Moscovici’s theorem. Thus, we have the formula

\[
\langle \text{Ch(Ind} \tilde{D}_A), \tau_\eta \cup \tau_\xi \rangle = c \int_{M \times N} \hat{A}(M \times N) \wedge i^* \text{ch}(\hat{\mathcal{E}}|_{M \times A}) \wedge f^*\eta \wedge j^*\xi \in \mathbb{C}
\]

for \( A \in B \). Moreover, by proposition 4.21 \( \text{Ch(Ind} \tilde{D}_A) \) is completely determined by this formula. In our family case, the proof in [9] goes in a parallel way with coefficient, and hence we obtain the family version

\[
(5.5) \quad \langle \text{Ch(Ind} \tilde{D}_A), \tau_\eta \cup \tau_\xi \rangle = c \int_{M \times N} \hat{A}(M \times N) \wedge i^* \text{ch}(\hat{\mathcal{E}}|_{M \times B}) \wedge f^*\eta \wedge j^*\xi \in H^*(B).
\]
More precisely \([\tilde{\tau}_\eta \cup \tilde{\tau}_\xi] \in \text{Hom}(K_*\left(C^*_r(\Gamma) \otimes C^*_r(\Gamma)\right), \mathbb{C})\) is paired with

\[
\text{Ind} \mathbb{D} \in K_0(C(B)) \otimes K_0(C^*_r(\Gamma) \otimes C^*_r(\Gamma))
\]

under the Künneth formula on periodic cyclic homology \([13]\). Notice that this is the Atiyah-Singer’s index theorem for family, when the group cocycle is trivial.

Now the equalities hold since \(\hat{A}(M) = 1\) by \(\dim M \leq 3\)

\[
\langle [\eta] \otimes [\xi] \otimes [C], \mu(\alpha, \beta) \rangle
\]

\[
= \langle (i \times \text{id})^* \text{ch}(\hat{E}) \wedge \hat{A}(N) \wedge f^*\eta \wedge j^*\xi, [M \times N \times C] \rangle
\]

\[
= \langle (i \times \text{id})^* \text{ch}(\hat{E}) \wedge f^*\eta, [M \times C] \rangle \langle \hat{A}(N) \wedge j^*\xi, [N] \rangle \in \mathbb{C}
\]

under the isomorphism

\[
H_k(B) \cong H^k(C^\infty(B)) \quad [C] \mapsto [\tau_C].
\]

The formula (5.5) is obtained.

Now similarly to the proof of proposition \([4,21]\) \(\text{Ch(Ind} \mathbb{D})\) is determined by this formula because \(\Gamma\) is admissible.

q.e.d.

Let us choose a closed submanifold \(B \subset \mathfrak{M}(\hat{E})\) (see proposition \([2,6]\))

\[
B \equiv V(\hat{E}, \hat{g}; \Sigma_0, M_1, \ldots, M_d) = \mathfrak{M}(\hat{E}) \cap V_{\Sigma_0} \cap V_{M_1} \cap \cdots \cap V_{M_d}.
\]

Here, \(\dim \mathfrak{M}(E) = \sum_{k=1}^d (4 - \dim M_k) + r\) with \(\dim B = r = 1, 2\). Note that the homology class of \(B\) depends on \(A^\pi(X)\), i.e., \([B]\) depends only on \(\hat{E}\), the homotopy class \([M_j : S^1 \to X] \in \pi_1(X)\) with \(\dim M_j = 1\) and the homology class \([M_j] \in H_*(X; \mathbb{Z})\) with \(\dim M_j \geq 2\).

**Definition 5.7.** Let us fix a smooth algebra \(C^\infty(\Gamma)\). The twisted Donaldson invariant is given by a map

\[
\Psi_{X, f}^{\text{tw}, (r)} : A^\pi(X) \times (\Omega^{\text{Spin}}(X) \otimes \Omega^{\text{Spin}}(B\Gamma)) \to H^r(C^\infty(\Gamma) \otimes C^\infty(\Gamma)),
\]

\[
( [M_1], \ldots, [M_d], \alpha, \beta ) \mapsto \frac{1}{2 \cdot 4d_0} \langle \mu^{\text{tw}}(\alpha, \beta), [B] \rangle.
\]

Here, \(\dim B = r = 1, 2\) and \(d_0\) is the number of homology classes \([M_j]\) of degree 0.

In particular this gives rise to the map

\[
\Psi_{X, f}^{\text{tw}, (r)} : A^\pi(X) \times (\Omega^{\text{Spin}}(X) \otimes \Omega^{\text{Spin}}(B\Gamma)) \to H_* (\Gamma; \mathbb{C}) \otimes H_* (\Gamma; \mathbb{C})
\]

when \(\Gamma\) satisfies the conditions of lemma \([4,10]\) for example, when \(\Gamma\) is a free abelian group.

**Remark 5.8.** Recall that when \(\Gamma\) admits a cohomological formula in the sense of theorem \([5,6]\) \(\pi_1(X)\) can be reduced to \(H_1(X; \mathbb{Z})\) and \(A^\pi(X)\) can be simplified to the form \(A(X)\) in \([1,2]\).
5.3. **Relation to the commutative case.** Suppose \( \Gamma \) is free abelian. So \( \Gamma \) is admissible. The space of irreducible representations \( \hat{\Gamma} = \text{Pic}(B\Gamma) \) is isomorphic to a torus, and Fourier transform gives rise to the isomorphism

\[
C^*_r(\Gamma) \cong C_0(\hat{\Gamma}) = \bigcup_{a \in \hat{\Gamma}} C_a
\]

where \( C_a \) stands for the one dimensional complex representation space of the character \( a \in \hat{\Gamma} \).

**Lemma 5.9.** The higher index \( \text{Ind} \tilde{D}_A \in K_0(C^*_r(\Gamma) \otimes C^*_r(\Gamma)) \) coincides with the index for family with the value in \( K^0(\hat{\Gamma} \times \hat{\Gamma}) \), passing through the above isomorphism.

**Proof.** \( C^*_r(\Gamma) \) bundle \( \gamma \) over \( B\Gamma \) is a family of line bundles over \( B\Gamma \times \hat{\Gamma} \)

\[
\gamma := E\Gamma \times \Gamma C^*_r(\Gamma) = E\Gamma \times (\bigcup_{a \in \hat{\Gamma}} \mathbb{C}_a) = \bigcup_{a \in \hat{\Gamma}} E\Gamma \times \mathbb{C}_a
\]

which is nothing but the universal line bundle \( L \).

Now we have the line bundle over \( B\Gamma \times \hat{\Gamma} \times B\Gamma \times \hat{\Gamma} \)

\[
\gamma \boxtimes \gamma = \bigcup_{a,b \in \hat{\Gamma}} (E\Gamma \times \mathbb{C}_a) \boxtimes (E\Gamma \times \mathbb{C}_b).
\]

Denote by \( L_a \) the summand \( E\Gamma \times \mathbb{C}_a \), and consider a bundle with connection

\[
\mathbb{E}|_{M \times \{A\}} \boxtimes_M [(f \circ i)^*L_a \otimes j^*L_b] \to M \times N
\]

where the connection is given by \( A|_M \) on \( E|_M \) and the induced flat connection on \( (f \circ i)^*L_a \otimes j^*L_b \). Let \( D_{A,a,b} \) be the Dirac operator \( D \) on \( M \times N \) twisted by this connection. Then \( \{D_{A,a,b}\}_{a,b \in \hat{\Gamma}} \) is a continuous family of Dirac operators whose family index takes the value

\[
(\text{ind} D_{A,a,b})_{a,b \in \hat{\Gamma}} \in K^0(\hat{\Gamma} \times \hat{\Gamma})
\]

which corresponds the higher index:

\[
\text{Ind} \tilde{D}_A \in K_0(C^*_r(\Gamma) \otimes C^*_r(\Gamma)).
\]

q.e.d.

If we vary \( A \in B \), then the higher index

\[
\mathbb{D} = \{\tilde{D}_A\}_{A \in B}
\]

is also parametrised by \( B \subset \mathfrak{M}(\hat{E}) \). Under the isomorphism

\[
K_0(C(B, C^*_r(\Gamma) \otimes C^*_r(\Gamma))) \cong K^0(B \times \hat{\Gamma} \times \hat{\Gamma}),
\]

the higher index for family in Section 5.1

\[
\text{Ind} \mathbb{D} = \{\text{Ind} \tilde{D}_A\}_{A \in B} \in K_0(C(B, C^*_r(\Gamma) \otimes C^*_r(\Gamma)))
\]

corresponds to the index for family

\[
(\text{ind} D_{A,a,b})_{A \in B,a,b \in \hat{\Gamma}} \in K^0(B \times \hat{\Gamma} \times \hat{\Gamma}).
\]

The image of the Chern character of the index for family takes the value

\[
\mu^\text{tw}_r(\alpha, \beta) = \text{Ch}(\text{Ind} \mathbb{D}) \in H^{\text{even}}(B \times \hat{\Gamma} \times \hat{\Gamma}; \mathbb{C}) \cong \text{HP}_0(C^\infty(B) \otimes C^\infty(\Gamma) \otimes C^\infty(\Gamma)).
\]

by lemma 4.16.
So far we have constructed two versions of the twisted \( \mu \) maps
\[
\mu_{tw,ab}^{\pm}(\alpha, \beta) \in HP_0(C^\infty(B) \otimes C^\infty(\Gamma)),
\mu_t^{\pm}(\alpha, \beta) \in HP_0(C^\infty(B) \otimes C^\infty(\Gamma) \otimes C^\infty(\Gamma))
\]
and the twisted Donaldson’s maps
\[
\Psi_{X,f,ab}^{tw,r}: A(X) \otimes H_*(X; \mathbb{Z}) \otimes \Omega^{Spin}(B\Gamma) \to HP_*(C^\infty(\Gamma)),
\Psi_{X,f}^{tw,r}: A(X) \otimes H_*(X; \mathbb{Z}) \otimes \Omega^{Spin}(B\Gamma) \to HP_*(C^\infty(\Gamma) \otimes C^\infty(\Gamma)).
\]
where in both cases the formers are given in section 3 and the latters are in section 5 (\( ab \) stands for ‘abelian’).

Let us describe their relations below. Let
\[
\Delta : \hat{\Gamma} \to \hat{\Gamma} \times \hat{\Gamma}
\]
be the diagonal map.

**Proposition 5.10.** Suppose \( \pi_1(X) = \Gamma \) is free abelian. then they satisfy the following relations
\[
\Delta^*(\Psi) = \Psi_{ab}, \quad \Delta^*(\mu(\alpha, \beta)) = \mu_{ab}(\alpha, \beta).
\]

**Proof.** Recall the commutative case in section 3
\[
\mathbb{E}|_{M \times B} \boxtimes_X (f \circ i)^*\mathbb{L} \boxtimes \text{Pic} j^*\mathbb{L} \to M \times N \times B
\]
where \( \mathbb{L} \to B\Gamma \times \hat{\Gamma} \) is the universal family of flat line bundles defined in section 3.

Notice that the fibered product
\[
\mathbb{L} \boxtimes \text{Pic} \mathbb{L} = \{(ET \times \Gamma ET) \times \Gamma \mathbb{C}_a\}_{a \in \hat{\Gamma}} \to B\Gamma \times B\Gamma \times \hat{\Gamma}
\]
is obtained by restricting \( \gamma \boxtimes \gamma \) over the diagonal in \( \hat{\Gamma} \times \hat{\Gamma} \)
\[
\gamma \boxtimes \text{Pic} \gamma = \bigsqcup_{a \in \hat{\Gamma}} (ET \times \Gamma \mathbb{C}_a) \boxtimes (ET \times \Gamma \mathbb{C}_a) \to B\Gamma \times B\Gamma \times \hat{\Gamma}.
\]
Then it follows from naturality that the equalities hold:
\[
\Delta^* \text{Ch}(\text{ind}\{D_{A,a,b}\}_{A \in B,a,b \in \hat{\Gamma}}) = \text{Ch}(\Delta^* \text{ind}\{D_{A,a,b}\}_{A \in B,a,b \in \hat{\Gamma}}) = \text{Ch}(\text{ind}\{D_{A,a}\}_{A \in B,a \in \hat{\Gamma}}).
\]
q.e.d.

**Remark 5.11.** Notice that the diagonal map induces a \( * \)-homomorphism
\[
C_0(\hat{\Gamma}) \otimes C_0(\hat{\Gamma}) \to C_0(\hat{\Gamma})
\]
but in general, there are no such homomorphism \( C_0^*(\Gamma) \otimes C_0^*(\Gamma) \to C_0^*(\Gamma) \) if \( \Gamma \) is non commutative.
