We utilize an exact variational numerical procedure to calculate the ground-state properties of a polaron in the presence of Rashba and linear Dresselhaus spin-orbit coupling. We find that when the linear Dresselhaus spin-orbit coupling approaches the Rashba spin-orbit coupling, the Van Hove singularity in the density of states will be shifted away from the bottom of the band and finally disappear when the two spin-orbit couplings are tuned to be equal. The effective mass will be suppressed; the trend will become more significant for low phonon frequency. The presence of two dominant spin-orbit couplings will make it possible to tune the effective mass with more varied observables.

I. INTRODUCTION

One of the end goals in condensed matter physics is to achieve a sufficient understanding of materials fabrication and design so as to “tailor engineer” specific desired properties into a material. Arguably p-n junctions long ago represented some of the first steps in this direction; now heterostructures1 and mesoscopic geometries2 represent further progress toward this goal.

In the field of spintronics, where the spin degree of freedom is specifically exploited for potential applications,3,4 spin-orbit coupling5 plays a critical role because control of spin will require coupling to the orbital motion. Spin-orbit coupling, as described by Rashba6 and Dresselhaus,7 is expected to be prominent in two-dimensional systems that lack inversion symmetry, including surface states. These different kinds of coupling are in principle independently controlled.3,5

The coexistence of Rashba and Dresselhaus spin-orbit coupling has now been realized in both semiconductor quantum wells3,8,9 and more recently, in a neutral atomic Bose-Einstein condensate.10 When the Rashba and (linear) Dresselhaus spin-orbit coupling strengths are tuned to be equal, SU(2) symmetry is predicted to be recovered and the persistent spin helix state will emerge.4,10,11 This symmetry is expected to be robust against spin-independent scattering but is broken by the cubic Dresselhaus spin-orbit coupling and other spin-dependent scattering which may be tuned to be negligible.4

While we focus on the spin-orbit interaction, other interactions are present. In particular, the electron-phonon interaction will be present and may be strong in semiconductor heterostructures. Moreover, optical lattices12 with cold polar molecules may be able to realize a tunable Holstein model.13 The primary purpose of this work is to investigate the impact of electron-phonon coupling (as modeled by the Holstein model)14 on the properties of the spin-orbit coupled system. We will utilize a tight-binding framework; previously it was noted that in the presence of Rashba spin-orbit coupling the vicinity of a Van Hove singularity near the bottom of the electron band15–17 had a significant impact on the polaronic properties of an electron; with additional (linear) Dresselhaus spin-orbit coupling the Van Hove singularity shifts well away from the band bottom as the two spin-orbit couplings acquire equal strength. As we will illustrate below, the presence of two separately tunable spin-orbit couplings will result in significant controllability of the electron effective mass.

II. MODEL AND METHODOLOGIES

We use a tight-binding model with dimensionless Holstein electron-phonon coupling of strength $g$ and with linear Rashba ($V_R$) and Dresselhaus ($V_D$) spin-orbit coupling:

$$H = -t \sum_{\langle i,j \rangle, \alpha=\uparrow,\downarrow} (c^\dagger_{i,\alpha} c_{j,\alpha} + c^\dagger_{j,\alpha} c_{i,\alpha})$$

$$+ i \sum_{j} (c^\dagger_{j,\alpha} \hat{V}_j c_{j+\hat{y},\alpha} - c^\dagger_{j,\alpha} \hat{V}_j c_{j+\hat{y},\alpha} - \text{h.c.})$$

$$- g \omega_E \sum_{i,\alpha=\uparrow,\downarrow} c^\dagger_{i,\alpha} c_{i,\alpha} (a^\dagger_i + a^\dagger_i)$$

$$+ \omega_E \sum_{i,\alpha=\uparrow,\downarrow} a^\dagger_i a_i + \text{h.c.},$$

where $c^\dagger_{i,\alpha} (c_{i,\alpha})$ creates (annihilates) an electron at site $i$ with spin index $\alpha$, and $a^\dagger_i (a_i)$ creates (annihilates) a phonon at site $i$. The operators $\hat{V}_j$, $j = 1, 2$ are written in terms of the spin-orbit coupling strengths and the Pauli matrices as $\hat{V}_1 = V_R \delta_1 - V_D \delta_y$ and $\hat{V}_2 = V_R \delta_1 + V_D \delta_y$. The sum over $i$ is over all sites in the lattice, whereas $(i, j)$ signifies that only nearest-neighbor hopping is included. Other parameters in the problem are the phonon frequency $\omega_E$ and the hopping parameter $t$, which hereafter is set equal to unity.

Without the electron-phonon interaction, the electronic structure is readily obtained by diagonalizing the Hamiltonian in momentum space. With the definitions

$$S_1 \equiv V_R \cos(k_x) + V_D \sin(k_x),$$

$$S_2 \equiv V_R \sin(k_x) + V_D \sin(k_y),$$

we obtain the eigenvalues

$$\varepsilon_{k,\pm} = -2t [\cos(k_x) + \cos(k_y)] \pm 2\sqrt{S_1^2 + S_2^2}$$

and eigenvectors

$$\Psi_{k,\pm} = \frac{1}{\sqrt{2}} \left[ c^\dagger_{k,\uparrow} \pm \frac{S_1 - iS_2}{\sqrt{S_1^2 + S_2^2}} c^\dagger_{k,\downarrow} \right] \langle 0 \rangle.$$
The ground-state energy is
\[
E_0 = -4t\sqrt{1 + (V_R + V_D)^2/(2t^2)}.
\]
Without loss of generality we can consider only \(V_R \geq 0\) and \(V_D \geq 0\). Independently, Rashba and Dresselhaus spin-orbit coupling behave in the same manner and give rise to a four-fold degenerate ground state with wave vectors \((k_x, k_y) = [\pm \arctan(V_R/t), \pm \arctan(V_D/t)]\), \((V_D = 0)\), and similarly for \(V_D \neq 0\) and \(V_R = 0\). With both couplings nonzero, however, the degeneracy becomes twofold with the ground-state wave vectors
\[
(k_{x0}, k_{y0}) = \pm (k_0, 0); \quad \text{where} \quad k_0 = \tan^{-1}\left(\frac{V_R + V_D}{\sqrt{2t}}\right).
\]
Contour plots of the energy dispersion are given for several different parameter sets in Fig. 1. It is clear that the sum of the coupling strengths replaces the strength of either in these expressions, so that henceforth in most plots we will vary one of the spin-orbit interaction strengths while maintaining their sum to be fixed. Similarly, the effective mass taken along the diagonal is
\[
m_{SO} = \frac{1}{\sqrt{1 + (V_R + V_D)^2/(2t^2)}},
\]
where \(m_0 = 1/(2t)\) (lattice spacing, \(a = 1\), and \(h = 1\)) is the bare mass in the absence of spin-orbit interaction, and \(m_{SO}\) is the effective mass due solely to the spin-orbit interaction. As detailed in the Appendix, the effective mass becomes isotropic when the Rashba and Dresselhaus spin-orbit coupling strengths are equal.

The noninteracting electron density of states (DOS) is defined for each band as
\[
D_s(\epsilon) = \sum_k \delta(\epsilon - \epsilon_{ks})
\]
with \(s = \pm 1\).

In Fig. 2(a) we show the low-energy DOS for various values of the spin-orbit coupling strengths, \(V_R\) and \(V_D\), while keeping their sum constant; the low-energy Van Hove singularity disappears for \(V_R = V_D\). Note that only \(D_-(\epsilon)\) is shown, whereas the upper band, with DOS \(D_+(\epsilon)\), exists only at higher energies. Furthermore, information concerning the upper band can always be obtained through the symmetry
\[
D_+(\epsilon) = D_-(\epsilon).
\]
In Fig. 2(b) we show the value of the density of states at the bottom of the band vs \(V_D\); as derived in the Appendix, the DOS value at the minimum energy is given by
\[
D_-(E_0) = \frac{1}{2\pi t} \frac{1}{\sqrt{1 + (V_R + V_D)^2/(2t^2)} - (V_R - V_D)^2/(V_R + V_D)^2}.
\]
Note that when the coupling strengths are equal, the density of states has a minimum. Also note that when one kind of spin-orbit coupling vanishes, e.g., \(V_R = 0\) or \(V_D = 0\), there will be a discontinuity for the density of states (the DOS jumps to twice its value). This is caused by a transition from a doubly degenerate ground state to a fourfold degenerate ground state. This discontinuity will also appear for \(V_D \simeq 0\) or \(V_R \simeq 0\) near the bottom of the band, as can be seen from Fig. 2(a) for \(V_R = 0.99, V_D = 0.01\).

FIG. 1. (Color online) Contour plots for the bare energy bands with Rashba-Dresselhaus spin-orbit coupling for different values of \(V_R\) and \(V_D\) while the sum is kept constant, \(V_R + V_D = t\) for these cases: (a) \(V_R = V_D = 0.5t\); (b) \(V_R = 0.8t, V_D = 0.2t\); (c) \(V_R = 0.9t, V_D = 0.1t\); and (d) \(V_R = 0.99t, V_D = 0.01t\). Note the clear progression from a twofold degenerate ground state to a fourfold degenerate one.
III. RESULTS WITH THE ELECTRON-PHONON INTERACTION

As the electron-phonon interaction is turned on, the ground-state energy (effective mass) will decrease (increase) due to polaron effects. To study the polaron problem numerically, we adopt the variational method outlined by Trugman and co-workers,18,19 which is a controlled numerical technique to determine polaron properties in the thermodynamic limit exactly. This method was recently further developed20,21 to study the polaron problem near the adiabatic limit with Rashba spin-orbit coupling.17 This case was also studied in Ref.16 using the momentum average (MA) approximation.22

In Fig. 3 we show the ground-state energy and the effective mass correction as a function of the electron-phonon coupling \( \lambda \equiv 2g^2\omega_E/(4\pi t) \) (Ref. 20) for various spin-orbit coupling strengths but with the sum fixed: \( V_R + V_D = t \). These are compared with the results from the Rashba-Holstein model with \( V_D = 0 \). Here the phonon frequency is set to be \( \omega_E/t = 1.0 \), which is the typical value used in Ref. 16, and for each value of \( V_R \), the ground-state energy is compared to the corresponding result for \( \lambda = 0 \). The numerical results are compared with results from the MA method and from Lang-Firsov strong-coupling theory23,24 (see Appendix). In Fig. 3(a), the ground-state energy crosses over smoothly (at around \( \lambda \approx 0.8 \)) from the delocalized electron regime to the small polaron regime. In the whole regime, the ground-state energy is shifted up slightly as the Dresselhaus spin-orbit coupling \( V_D \) is increased in lieu of the Rashba spin-orbit coupling. We show results for \( V_D \leq V_R \), as the complementary regime is completely symmetric. The MA results agree very well with the exact results, and the Lang-Firsov strong-coupling results agree well in the \( \lambda \geq 1 \) regime. Similarly, weak coupling perturbation theory17 agrees with the exact results for \( \lambda \leq 1 \) (not shown). Figure 3(b) shows the effective mass as a function of coupling strength; it decreases slightly, for a given value of \( \lambda \), by increasing \( V_D \) in lieu of \( V_R \).
IV. SUMMARY

Linear spin-orbit coupling can arise in two varieties. Taken on their own, they are essentially equivalent and their impact on a single electron, even in the presence of electron-phonon interactions, will be identical. However, with the ability to tune either coupling constant, in both solid-state and cold-atom experiments, one can probe the degree of Dresselhaus vs Rashba spin-orbit coupling through the impact on polaronic properties. The primary effect of this variation is the electron density of states, where the Van Hove singularity can be moved as a function of chemical potential (i.e., doping) through tuning of the spin-orbit parameters. These conclusions are based on exact methods (the so-called Trugman method) and are not subject to approximations. These results have been further corroborated and understood through the momentum average perturbation theory. The effect is expected to be experimentally relevant, since in typical materials with large spin-orbit couplings the phonon frequency is small when compared to the bandwidth, \( \omega_E / t \ll 1 \).

APPENDIX A: DENSITY OF STATES AND EFFECTIVE MASS

By expanding \( \varepsilon_{k,-} \) around the minimum energy \( E_0 \) and defining \( k'_c = k_c \pm \arctan(\frac{V_R + V_D}{\sqrt{D}}) \), \( k'_y = k_y \pm \arctan(\frac{V_R + V_D}{\sqrt{D}}) \), we have

\[
\varepsilon_{k,-} = E_0 + \tilde{t}_1 \left\{ k_x^2 + k_y^2 \right\} \pm \tilde{t}_2 k'_c k'_y,
\]

where

\[
\tilde{t}_1 = t \left\{ 1 + \frac{(V_R + V_D)^2}{2t^2} - \frac{(V_R - V_D)^2}{(V_R + V_D)^2} \right\}^{1/2}/(2t^2) \quad (A2)
\]

and

\[
\tilde{t}_2 = t \left\{ \frac{(V_R - V_D)^2}{(V_R + V_D)^2} \right\}^{1/2}/(2t^2). \quad (A3)
\]

Note that with generic spin-orbit coupling, the effective mass is in general anisotropic, but when \( V_D = V_R \), it becomes isotropic.

To calculate the density of states at the bottom of the band, from the definition we have

\[
D_-(E_0 + \delta E) = \frac{1}{4\pi^2} \int_{\pi} -\pi dk_x \int_{\pi} -\pi dk_y \delta(E_0 + \delta E - \varepsilon_{k,-}),
\]

where \( \delta E \) is a small amount of energy above the bottom of the band \( E_0 \). Around the two energy minimum points there are two small regions which will contribute to this integral. We choose one of them (and then multiply our result by a factor of 2), then use the definitions of \( k' \) above instead of \( k \), and introduce...
a small cutoff $k_\text{c}$, which is the radius of a small circle around $k_{\text{min}}$. Thus the integral becomes

$$D_-(E_0 + \delta E) = 2\times \frac{1}{4\pi^2} \int_0^{k_\text{c}} k' dk' \int_{-\pi}^{\pi} d\theta \delta \left[ \delta E - \left\{ \tilde{t}_1 + \frac{1}{2} \tilde{t}_2 \sin 2\theta \right\} k'^2 \right]$$

$$= \frac{1}{2\pi t} \sqrt{1 + \frac{(k_\text{c} + \tilde{v})^2}{2\tilde{t}_2^2} - \frac{(k_\text{c} - \tilde{v})^2}{2\tilde{t}_2^2}}.$$

(A5)

In the weak electron-phonon coupling regime, perturbation theory can be applied to evaluate the effective mass; the self-energy to first order in $\lambda$ is given by

$$\Sigma_{\text{weak}}(\omega + i\delta) = \pi \lambda t \omega E \sum_{k_{\text{r},\pm}} \frac{1}{\omega + i\delta - \omega_E - \epsilon_{k_{\text{r}}}}.$$

(A6)

The effective mass can be obtained through the derivative of the self-energy

$$\frac{m^*_\text{weak}}{m_{\text{SO}}} = 1 - \frac{\partial}{\partial \omega} \Sigma_{\text{weak}}(\omega + i\delta)|_{\omega=\omega_0}.$$  

(A7)

By inserting the expansion of $\epsilon_{k_{\text{r}}}$ around the minimum energy $E_0$ into Eqs. (A6) and (A7), we obtain the effective mass near the adiabatic limit as

$$\frac{m^*_\text{weak}}{m_{\text{SO}}} = 1 + \frac{\lambda}{2} \frac{1}{\sqrt{1 + \frac{(k_\text{c} + \tilde{v})^2}{2\tilde{t}_2^2} - \frac{(k_\text{c} - \tilde{v})^2}{2\tilde{t}_2^2}}}.$$  

(A8)

The effective mass has a minimum for $V_R = V_D$ while $V_R + V_D$ is a constant.

APPENDIX B: STRONG COUPLING THEORY

To investigate the strong-coupling regime of the Rashba-Dresselhaus-Holstein model for a single polaron, we use the Lang-Firsov\textsuperscript{23,24} unitary transformation $\tilde{H} = e^{\delta H} e^{-\delta}$, where $S = g \sum_{i,\sigma} n_{i,\sigma} (\alpha_i - \bar{a}_i)$. Following procedures similar to those in Ref. 17, we obtain the first-order perturbation correction to the energy as

$$E^{(1)}_{k_{\text{r}}} = e^{-g^2} \epsilon_{k_{\text{r}}} - g^2 \omega E,$$

(B1)

where $g$ is the band narrowing factor, as used in the Holstein model. To find the second-order correction to the ground-state energy, we proceed as in Ref. 17 and find

$$E^{(2)}_{k_{\text{r}}} = -4e^{-2g^2} \frac{t^2}{\omega E} \left[ (V_R)^2 + (V_D)^2 \right]$$

$$\times \left\{ f(2g^2) - f(g^2) \right\} - e^{-2g^2} f(g^2) \frac{\epsilon^2_{k_{\text{r}}}}{\omega E},$$

(B2)

where $f(x) \equiv \sum_{n=1}^{\infty} \frac{1}{n!} \approx e^x [1 + 1/x + 2/x^2 + \cdots]$. Thus the ground-state energy, excluding exponentially suppressed corrections, is

$$E_{\text{GS}} = -2\pi \lambda \left( 1 + \frac{t^2}{\omega E} \left[ (V_R)^2 + (V_D)^2 \right] \right),$$

(B3)

and there is a correction of order $1/\lambda^2$ compared to the zeroth-order result. Corrections in the dispersion enter in strong coupling only with an exponential suppression. The ground-state energy predicted by strong-coupling theory has a maximum for $V_R = V_D$, while $V_R + V_D$ is a constant.
