Abstract
Let $S^{(\Lambda)}$ denote the classical Littlewood–Paley operator formed with respect to a lacunary sequence $\Lambda$ of positive integers. Motivated by a remark of Pichorides, we obtain sharp asymptotic estimates of the behaviour of the operator norm of $S^{(\Lambda)}$ from the analytic Hardy space $H_p^A(\mathbb{T})$ to $L_p(\mathbb{T})$ and of the behaviour of the $L_p(\mathbb{T}) \to L_p(\mathbb{T})$ operator norm of $S^{(\Lambda)}$ $(1 < p < 2)$ in terms of the ratio of the lacunary sequence $\Lambda$. Namely, if $\rho_\Lambda$ denotes the ratio of $\Lambda$, then we prove that
\[
\sup_{\|f\|_{L_p(\mathbb{T})}=1} \left\| S^{(\Lambda)}(f) \right\|_{L_p(\mathbb{T})} \lesssim \frac{1}{p - 1} (\rho_\Lambda - 1)^{1/2} \quad (1 < p < 2)
\]
and
\[
\left\| S^{(\Lambda)} \right\|_{L_p(\mathbb{T}) \to L_p(\mathbb{T})} \lesssim \frac{1}{(p - 1)^{3/2}} (\rho_\Lambda - 1)^{1/2} \quad (1 < p < 2)
\]
and that these results are optimal as $p \to 1^+$. Variants in higher dimensions and in the Euclidean setting are also obtained.

1 Introduction

Given a strictly increasing sequence \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) of positive integers, consider the corresponding Littlewood–Paley projections \( (\Delta_j^{(1)})_{j \in \mathbb{N}_0} \) given by

\[
\Delta_j^{(1)} := \begin{cases} 
S_{\lambda_0}, & \text{if } j = 0 \\
S_{\lambda_j} - S_{\lambda_{j-1}}, & \text{if } j \in \mathbb{N} 
\end{cases}
\]

where, for \( N \in \mathbb{N} \), \( S_N \) denotes the multiplier operator acting on functions over \( \mathbb{T} \) with symbol \( \chi_{\{-N+1, \ldots, N-1\}} \). Define the Littlewood–Paley square function \( S^{(1)}(g) \) of a trigonometric polynomial \( g \) by

\[
S^{(1)}(g) := \left( \sum_{j \in \mathbb{N}_0} |\Delta_j^{(1)}(g)|^2 \right)^{1/2}.
\]

It is well known that in the case where \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) is a lacunary sequence in \( \mathbb{N} \), namely the ratio \( \rho_\Lambda := \inf_{j \in \mathbb{N}_0} (\lambda_{j+1}/\lambda_j) \) is greater than 1, then \( S^{(1)} \) can be extended as a sublinear \( L^p(\mathbb{T}) \) bounded operator for \( 1 < p < \infty \); see [19] or [45] for the periodic case and [40] for the Euclidean case.

In 1989, in [13], Bourgain proved that if \( \Lambda_D := (2^j)_{j \in \mathbb{N}_0} \), then the \( L^p(\mathbb{T}) \to L^p(\mathbb{T}) \) operator norm of the Littlewood–Paley operator \( S^{(\Lambda_D)} \) behaves like \((p - 1)^{-3/2}\) as \( p \to 1^+ \), namely

\[
\left\| S^{(\Lambda_D)} \right\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \sim (p - 1)^{-3/2} \quad (1 < p \leq 2), \tag{1.1}
\]

Other proofs of the aforementioned theorem of Bourgain were obtained by the author in [2] and by Lerner in [30].

In 1992, in [35], Pichorides showed that if we restrict ourselves to the analytic Hardy spaces, then one has the improved behaviour \((p - 1)^{-1}\) as \( p \to 1^+ \). More specifically, Pichorides proved in [35] that if \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) is a lacunary sequence of positive integers, then one has

\[
\sup_{\|f\|_{L^p(\mathbb{T})} = 1} \left\| S^{(\Lambda)}(f) \right\|_{L^p(\mathbb{T})} \sim \frac{1}{p - 1} \quad (1 < p \leq 2), \tag{1.2}
\]

where the implied constants in (1.2) depend only on the lacunary sequence \( \Lambda \) and not on \( p \). As remarked by Pichorides, see Remark (i) in [35, Sect. 3], if \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) is a lacunary sequence in \( \mathbb{N} \) with ratio \( \rho_\Lambda \in (1, 2) \), then the argument in [35] yields that for fixed \( 1 < p < 2 \) the implied constant in the upper estimate in (1.2) is \( O((\rho_\Lambda - 1)^{-2}) \).

Our main purpose in this paper is to solve the aforementioned problem implicitly posed by Pichorides in [35] and more specifically, our goal is to improve the exponent \( r = 2 \) in \((\rho_\Lambda - 1)^{-2}\) obtained in [35] to the following optimal estimate.
Theorem 1 There exists an absolute constant $C_0 > 0$ such that for every $1 < p < 2$ and for every lacunary sequence $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ in $\mathbb{N}$ with ratio $\rho_\Lambda \in (1, 2)$ one has

$$\sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \leq \frac{C_0}{p - 1}(\rho_\Lambda - 1)^{-1/2}. \quad (1.3)$$

The exponent $r = 1/2$ in $(\rho_\Lambda - 1)^{-1/2}$ in (1.3) is asymptotically optimal in the following sense. For every $\lambda$ ‘close’ to $1^+$, one can construct a lacunary sequence $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ in $\mathbb{N}$ with ratio $\rho_\Lambda \in (\lambda, \lambda^2)$ satisfying

$$(\rho_\Lambda - 1)^{-1/2} \lesssim \liminf_{p \to 1^+} \left[ (p - 1) \sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \right], \quad (1.4)$$

which combined with (1.3) implies that

$$(\rho_\Lambda - 1)^{-1/2} \lesssim \liminf_{p \to 1^+} \left[ (p - 1) \sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \right] \leq \limsup_{p \to 1^+} \left[ (p - 1) \sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \right] \lesssim (\rho_\Lambda - 1)^{-1/2}. \quad (1.5)$$

One thus deduces that there is no exponent $\tau \in (0, 1/2)$ with the property that there exists an absolute constant $C > 0$ such that

$$\sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \leq \frac{C}{p - 1}(\rho_\Lambda - 1)^{-\tau}$$

for all $p \in (1, 2)$ and for each lacunary sequence $\Lambda$ with ratio $\rho_\Lambda \in (1, 2)$.

In addition, we establish here the optimal behaviour of the $L^p(\mathbb{T}) \to L^p(\mathbb{T})$ operator norm of $S^{(\Lambda)}$ in terms of the ratio $\rho_\Lambda$ of $\Lambda$. In other words, the following version of the aforementioned result of Bourgain (1.1) is obtained in this paper.

Theorem 2 There exists an absolute constant $C_0 > 0$ such that for every $1 < p < 2$ and for every lacunary sequence $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ in $\mathbb{N}$ with ratio $\rho_\Lambda \in (1, 2)$ one has

$$\|S^{(\Lambda)}\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \leq \frac{C_0}{(p - 1)^{3/2}}(\rho_\Lambda - 1)^{-1/2}. \quad (1.5)$$

Moreover, as in Theorem 1, the exponent $r = 1/2$ in $(\rho_\Lambda - 1)^{-1/2}$ in (1.5) cannot be improved in general, see also Remark 7 below.
The proofs of (1.3) and (1.5) are based on the observation that it suffices to show
\[ \| S^{(A)}(f) \|_{L^1(T)} \lesssim (\rho - 1)^{-1/2} \| f \|_X, \] (1.6)
where for the case of Theorem 1 one takes \( X \) to be the real Hardy space \( H^1(T) \) and for the case of Theorem 2, one takes \( X \) to be the Orlicz space \( L \log^{1/2} L(T) \).

Indeed, regarding the proof of Theorem 1, having established the aforementioned weak-type inequality, one then argues as in [7]. More precisely, (1.3) is obtained by using (1.6) for \( X = H^1(T) \), the trivial estimate \( \| S^{(A)} \|_{L^2(T) \to L^2(T)} = 1 \) and a result of Kislyakov and Xu on Marcinkiewicz-type interpolation between analytic Hardy spaces [26]. Regarding Theorem 2, having shown (1.6) for \( X = L \log^{1/2} L(T) \), the proof of (1.5) is obtained by arguing as in [2], namely by first interpolating between (1.6) for \( X = L \log^{1/2} L(T) \) and \( \| S^{(A)} \|_{L^2(T) \to L^2(T)} = 1 \) and then using Tao’s converse extrapolation theorem [42].

The proof of (1.6) for \( X = H^1(T) \) and \( X = L \log^{1/2} L(T) \) can be obtained by using appropriate variants of the arguments of Tao and Wright [43] that establish the endpoint mapping properties of general Marcinkiewicz multiplier operators ‘near’ \( L^1(R) \). However, we remark that for the case of Theorem 1, namely to prove (1.6) for \( X = H^1(T) \), one can use a version of Stein’s classical multiplier theorem on Hardy spaces [38,39] obtained by Coifman and Weiss in [16].

Furthermore, an adaptation of the aforementioned argument to the Euclidean setting, where one uses the work of Tao and Wright [43] combined with a theorem of Jones [25] on Marcinkiewicz-type decomposition for functions in analytic Hardy spaces on the real line, gives a Euclidean version of Theorem 1. Moreover, by using the work of Lerner [30], one obtains a variant of Theorem 2 to the Euclidean setting as well as an alternative proof of Theorem 2.

At this point, it is worth noting that, given any strictly increasing sequence \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) of positive integers, if \( 2 \leq p < \infty \) then \( S^{(A)} \) has an \( L^p(T) \to L^p(T) \) operator norm that is independent of \( \Lambda \). More specifically, Bourgain, by using duality and his extension [10] of Rubio de Francia’s theorem [37], proved in [13] that for every strictly increasing sequence \( \Lambda \) of positive integers the \( L^p(T) \to L^p(T) \) operator norm of \( S^{(A)} \) behaves like
\[ \| S^{(A)} \|_{L^p(T) \to L^p(T)} \lesssim p \quad (p \to \infty) \] (1.7)
and the implied constant in (1.7) does not depend on \( \Lambda \). In particular, if \( \Lambda \) is a lacunary sequence in \( \mathbb{N} \), then the implied constant in (1.7) is independent of \( \rho_\Lambda \) and the dependence in \( p \) is sharp; see [13, Theorem 2]. However, notice that Littlewood–Paley operators formed with respect to arbitrary strictly increasing sequences might not be bounded on \( L^p \) for any \( 1 < p < 2 \) as the example of the sequence \( \Lambda_I := (j + 1)_{j \in \mathbb{N}_0} \) shows; see e.g. [14]. For more details on Littlewood–Paley square functions of Rubio de Francia type, see [29] and the references therein. For sparse bounds for Littlewood–Paley operators of Rubio de type and for Marcinkiewicz-type multiplier operators in the Walsh–Fourier setting, see [15,22], respectively.

The present paper is organised as follows. In Sect. 2, we give some notation and background. In Sect. 3, we give a proof of Theorem 1 and present its optimality in the
sense explained above. In Sect. 4, we prove Theorem 2 and in Sect. 5, we extend our results to Littlewood–Paley operators formed with respect to finite unions of lacunary sequences. In Section 6, we extend (1.3) and (1.5) to higher dimensions and in the last section of this paper we obtain variants of (1.3) and (1.5) in the Euclidean setting.

2 Notation and Background

2.1 Notation

We denote the set of integers by \( \mathbb{Z} \), the set of natural numbers by \( \mathbb{N} \), and the set of non-negative integers by \( \mathbb{N}_0 \). The real line is denoted by \( \mathbb{R} \) and the complex plane by \( \mathbb{C} \). We identify strictly increasing sequences of positive integers with infinite subsets of \( \mathbb{N} \) in a standard way.

If \( x \in \mathbb{R} \), then \( \lfloor x \rfloor \) stands for the unique integer such that \( \lfloor x \rfloor - 1 < x \leq \lfloor x \rfloor \) and \( \lceil x \rceil \) denotes the integer part of \( x \) namely, \( \lfloor x \rfloor \) is the unique integer satisfying \( \lfloor x \rfloor \leq x < \lfloor x \rfloor + 1 \).

The notation \( | \cdot | \) is used for either the one-dimensional Lebesgue measure of a Lebesgue measurable set \( A \subseteq \mathbb{R}^d \) or for the modulus of a complex number \( a \in \mathbb{C} \).

The logarithm of \( x > 0 \) to the base \( \lambda > 0 \) is denoted by \( \log_\lambda (x) \). If \( \lambda = e \), we write \( \log x \).

If \( A \) is a finite set, then \( \#(A) \) denotes the number of its elements. Given \( a, b \in \mathbb{Z} \) with \( a < b \), \( \{a, \ldots, b\} \) denotes the set \([a, b] \cap \mathbb{Z}\) and will occasionally be referred to as an ‘interval’ in \( \mathbb{Z} \). Moreover, a function \( m : \mathbb{Z} \to \mathbb{R} \) is said to be ‘affine’ in \( \{a, \ldots, b\} \) if, and only if, there exists a function \( \mu : \mathbb{R} \to \mathbb{R} \) such that \( \mu(n) = m(n) \) for all \( n \in \{a, \ldots, b\} \) and \( \mu \) is affine in \([a, b] \).

If there exists an absolute constant \( C > 0 \) such that \( A \leq CB \), we shall write \( A \lesssim B \) or \( B \gtrsim A \) and say that \( A \) is \( O(B) \). If \( C > 0 \) depends on a given parameter \( \eta \), we shall write \( A \lesssim_\eta B \). If \( A \gtrsim B \) and \( B \lesssim A \), we write \( A \sim B \). Similarly, if \( A \lesssim_\eta B \) and \( B \lesssim_\eta A \), we write \( A \sim_\eta B \).

The class of Schwartz functions on \( \mathbb{R}^d \) is denoted by \( \mathcal{S}(\mathbb{R}^d) \).

If \( X_n \neq \emptyset \) and \( f_n : X_n \to \mathbb{C} \) is a function, \( n \in \{1, \ldots, d\} \), then the function \( f : X_1 \times \cdots \times X_d \to \mathbb{C} \) given by \( f(x_1, \ldots, x_d) := \prod_{n=1}^d f_n(x_n) \) is denoted by \( f_1 \otimes \cdots \otimes f_d \) or \( \bigotimes_{n=1}^d f_n \).

If \( J \) is a closed arc of the torus \( \mathbb{T} := \mathbb{R}/(2\pi \mathbb{Z}) \) with \( |J| < \pi \), then \( 2J \) denotes the closed arc that is concentric to \( J \) with length equal to \( 2|J| \). Similarly, if \( J \) is open or half-open.

We identify functions on the torus \( \mathbb{T} \) with \( 2\pi \)-periodic functions defined over the real line. The Fourier coefficient of a function \( f \) in \( L^1(\mathbb{T}^d) \) at \((n_1, \ldots, n_d)\in\mathbb{Z}^d \) is given by

\[
\hat{f}(n_1, \ldots, n_d) := (2\pi)^{-d} \int_{\mathbb{T}^d} f(x_1, \ldots, x_d) e^{-i(n_1x_1+\cdots+n_dx_d)} \, dx_1 \cdots dx_d.
\]

If \( f \in L^1(\mathbb{T}^d) \) is such that \( \text{supp}(\hat{f}) \) is finite, then \( f \) is said to be a trigonometric polynomial on \( \mathbb{T}^d \). If \( f \) is a trigonometric polynomial on \( \mathbb{T}^d \) such that \( \text{supp}(\hat{f}) \subseteq \mathbb{N}_0^d \),
then we say that $f$ is an analytic trigonometric polynomial on $\mathbb{T}^d$. If $f \in S(\mathbb{R}^d)$ then its Fourier transform at $(\xi_1, \ldots, \xi_d) \in \mathbb{R}^d$ is given by

$$\hat{f}(\xi_1, \ldots, \xi_d) := (2\pi)^{-d} \int_{\mathbb{R}^d} f(x_1, \ldots, x_d) e^{-i(\xi_1 x_1 + \cdots + \xi_d x_d)} \, dx_1 \ldots dx_d.$$  

Vector-valued functions on $\mathbb{T}$ are denoted by $F$. Moreover, for $0 < p < \infty$, we use the notation

$$\|F\|_{L^p(\mathbb{T}; \ell^2(\mathbb{N}))} := (2\pi)^{-1/p} \left( \int_{[-\pi, \pi]} \|F(x)\|_{\ell^2(\mathbb{N})}^p \, dx \right)^{1/p}.$$  

If $(X, \mathcal{A}, \mu)$ is a measure space, we use the standard notation

$$\|f\|_{L^1, \infty(X)} := \sup_{\alpha > 0} \{ \alpha \cdot \mu(\{ x \in X : |f(x)| > \alpha \}) \}.$$  

### 2.2 Multipliers

If $m \in \ell^\infty(\mathbb{Z}^d)$, then $T$ is said to be a multiplier operator with associated multiplier $m$ if, and only if, for every trigonometric polynomial $f$ on $\mathbb{T}^d$ one has the representation

$$T(f)(x_1, \ldots, x_d) = \sum_{(n_1, \ldots, n_d) \in \mathbb{Z}^d} m(n_1, \ldots, n_d) \hat{f}(n_1, \ldots, n_d) e^{i(n_1 x_1 + \cdots + n_d x_d)}$$  

for every $(x_1, \ldots, x_d) \in \mathbb{T}^d$. In this case, we also say that $m$ is the symbol of $T$ and we write $T = T_m$.

For $j \in \{1, \ldots, d\}$, if $T_j$ is the multiplier operator acting on functions over $\mathbb{T}$ with symbol $m_j \in \ell^\infty(\mathbb{Z})$, then $T_1 \otimes \cdots \otimes T_d$ or $\otimes_{k=1}^d T_k$ denotes the multiplier operator acting on functions over $\mathbb{T}^d$ whose associated symbol is given by $m(n_1, \ldots, n_d) = (\otimes_{k=1}^d m_k)(n_1, \ldots, n_d) = m_1(n_1) \ldots m_d(n_d)$ for all $(n_1, \ldots, n_d) \in \mathbb{Z}^d$.

Multiplier operators acting on functions over Euclidean spaces are defined similarly. Given a bounded function $m$ on $\mathbb{R}$, we denote by $T_{m|\mathbb{R}}$ the multiplier operator acting on functions defined over the torus with associated symbol given by $\mu = m|\mathbb{Z}$, i.e. $\mu : \mathbb{Z} \to \mathbb{C}$ and $\mu(n) = m(n)$ for all $n \in \mathbb{Z}$.

### 2.3 Function Spaces

The real Hardy space $H^1(\mathbb{T})$ is defined to be the class of all functions $f \in L^1(\mathbb{T})$ such that $H(f) \in L^1(\mathbb{T})$, where $H$ denotes the periodic Hilbert transform. For $f \in H^1(\mathbb{T})$, we set $\|f\|_{H^1(\mathbb{T})} := \|f\|_{L^1(\mathbb{T})} + \|H(f)\|_{L^1(\mathbb{T})}$. One defines the real Hardy space $H^1(\mathbb{R})$ on the real line in an analogous way.

It is well known that $H^1(\mathbb{T})$ admits an atomic decomposition. More specifically, following [16], a function $a$ is said to be an atom in $H^1(\mathbb{T})$ if it is either the constant function $a = \chi_I$ or there exists an arc $I$ in $\mathbb{T}$ such that $\text{supp}(a) \subseteq I$, $\int_I a(x) \, dx = 0$.  

 Springer
and \( \|a\|_{L^2(T)} \leq |I|^{-1/2} \). The characterisation of \( H^1(\mathbb{T}) \) in terms of atoms asserts that \( f \in H^1(\mathbb{T}) \) if, and only if, there exists a sequence of atoms \( (a_k)_{k \in \mathbb{N}} \) in \( H^1(\mathbb{T}) \) and a sequence \( (\mu_k)_{k \in \mathbb{N}} \in \ell^1(\mathbb{N}) \) such that

\[
f = \sum_{k \in \mathbb{N}} \mu_k a_k,
\]

where the convergence is in the \( H^1(\mathbb{T}) \)-norm and, moreover, if we define

\[
\|f\|_{H^1_{A}(\mathbb{T})} := \inf \left\{ \sum_{k \in \mathbb{N}} |\mu_k| : f = \sum_{k \in \mathbb{N}} \mu_k a_k, \ a_k \text{ are atoms in } H^1(\mathbb{T}) \right\},
\]

then there exist absolute constants \( c'_1, c_1 > 0 \) such that

\[
c'_1 \|f\|_{H^1_{A}(\mathbb{T})} \leq \|f\|_{H^1(\mathbb{T})} \leq c_1 \|f\|_{H^1_{A}(\mathbb{T})}.
\]  

(2.1)

For more details on real Hardy spaces, see [16,21,23] and the references therein.

For \( 1 \leq p < \infty \), one defines the \( d \)-parameter analytic Hardy space \( H^p_A(\mathbb{R}^d) \) as follows. A function \( f \in L^p(\mathbb{R}^d) \) belongs to \( H^p_A(\mathbb{R}^d) \) if, and only if, there exists an analytic function \( \tilde{f} \) on \( (\mathbb{R}^2_+)^d \) satisfying the condition

\[
\sup_{y_1,\ldots,y_d>0} \int_{\mathbb{R}^d} |\tilde{f}(x_1 + iy_1, \ldots, x_d + iy_d)|^p \, dx_1 \cdots dx_d < \infty
\]

so that \( f \) equals a.e. to the limit of \( \tilde{f} \) as one approaches the boundary \( \mathbb{R}^d \) of \( (\mathbb{R}^2_+)^d \), where \( \mathbb{R}^2_+ := \{ x + iy : x \in \mathbb{R}, y > 0 \} \). The Hardy space \( H^{\infty}_A(\mathbb{R}^d) \) is the class of all functions \( f \in L^\infty(\mathbb{R}^d) \) that are boundary values of bounded analytic functions \( \tilde{f} \) on \( (\mathbb{R}^2_+)^d \). One defines \( H^p_A(\mathbb{T}^d) \) in an analogous way \((1 \leq p < \infty)\). Also, it is well known that for \( 1 \leq p \leq \infty \) the Hardy space \( H^p_A(\mathbb{T}^d) \) coincides with the class of all functions \( f \in L^p(\mathbb{T}^d) \) such that \( \text{supp}(\tilde{f}) \subseteq N_0^d \). It thus follows that, in the one-dimensional case, \( H^1_A(\mathbb{T}) \subseteq H^1(\mathbb{T}) \) and \( \|f\|_{H^1(\mathbb{T})} = 2\|f\|_{L^1(\mathbb{T})} \) for all analytic trigonometric polynomials \( f \) on \( \mathbb{T} \). Moreover, the class of analytic trigonometric polynomials on \( \mathbb{T}^d \) is dense in \( H^p_A(\mathbb{T}^d) \), \( \| \cdot \|_{L^p(\mathbb{T}^d)} \) for all \( 1 \leq p < \infty \). For more details on one-dimensional analytic Hardy spaces, we refer the reader to the book [18].

For \( r > 0 \), \( L^r \log^r L(\mathbb{T}) \) denotes the class of all measurable functions \( f \) on the torus satisfying

\[
\int_{\mathbb{T}} |f(x)| \log^r(e + |f(x)|) \, dx < \infty.
\]

If we equip \( L^r \log^r L(\mathbb{T}) \) with the norm

\[
\|f\|_{L^r \log^r L(\mathbb{T})} := \inf \left\{ \lambda > 0 : (2\pi)^{-1} \int_{\mathbb{T}} \Phi_r(\lambda^{-1}|f(x)|) \, dx \leq 1 \right\},
\]

\( \Phi_r \) Springer
where $\Phi_r(t) := t[(1 + \log(1 + t))^r - 1]$, for $t \geq 0$, then $(L \log^r L(\mathbb{T}), \| \cdot \|_{L \log^r L(\mathbb{T})})$ becomes a Banach space. For more details on Orlicz spaces, see [28] and [36].

2.4 Maximal Operators

We denote the centred Hardy–Littlewood maximal operator in the periodic setting by $M_c$, namely if $f$ is a measurable function over $\mathbb{T}$ then one has

$$M_c(f)(x) := \sup_{0 < r \leq \pi} \frac{1}{2r} \int_{|t| < r} |f(x - t)| \, dt \quad (x \in \mathbb{T}).$$

The symbol $M_d$ stands for the centred discrete Hardy–Littlewood maximal operator given by

$$M_d(a)(n) := \sup_{N \in \mathbb{N}} \frac{1}{2N - 1} \sum_{|k| < N} |a(n - k)| \quad (n \in \mathbb{Z})$$

for any function $a : \mathbb{Z} \to \mathbb{C}$.

It is well known that $M_c$ is of weak-type $(1, 1)$ and bounded on $L^p(\mathbb{T})$ for every $1 < p \leq \infty$; see Chapter I in [40] or Sect. 13 in Chapter I in [45]. Analogous bounds hold for $M_d$; see [41].

If $f$ is a locally integrable function on the real line, then the non-centred Hardy–Littlewood maximal operator applied to $f$ is defined as

$$M(f)(x) := \sup_{x \in I} \frac{1}{|I|} \int_I |f(y)| \, dy \quad (x \in \mathbb{R}).$$

If $f$ is a locally integrable function on $\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_d}$, then its strong maximal function is given by

$$M_S(f)(x_1, \ldots, x_d) := \sup_{x_i \in I_1, \ldots, x_d \in I_d \text{ intervals}} \frac{1}{|I_1| \cdots |I_d|} \int_{I_1 \times \cdots \times I_d} |f(y_1, \ldots, y_d)| \, dy_1 \cdots dy_d.$$

Notice that since $M_S(f) \leq (M_1 \circ \cdots \circ M_d)(f)$, where $M_i$ denotes the non-centred Hardy–Littlewood maximal operator taken in the $i$-th variable, and $\|M\|_{L^p(\mathbb{R})} \rightarrow L^p(\mathbb{R})$ behaves like $(p - 1)^{-1}$ as $p \to 1^+$; see e.g. p. 22 in [40], one deduces that

$$\|M_S\|_{L^p(\mathbb{R}^d)} \rightarrow L^p(\mathbb{R}^d) \lesssim (p - 1)^{-d} \quad (p \to 1^+), \tag{2.2}$$

where the implied constant is independent of $p$.  

 Springer
2.5 $A_p$ Weights

If $B \subset \mathbb{R}^d$ is a measurable set with $|B| < \infty$ and $\sigma$ a locally integrable function on $\mathbb{R}^d$, we use the standard notation

$$(\sigma)_B := |B|^{-1} \int_B \sigma(x_1, \ldots, x_d) dx_1 \ldots dx_d.$$  

Let $p \in (1, \infty)$. A non-negative, locally integrable function $w$ on the real line is said to be an $A_p(\mathbb{R})$ weight if, and only if,

$$[w]_{A_p(\mathbb{R})} := \sup_{I \text{ interval}} \left\{ (w)_I \left( w^{1-p'} \right)_I^{p-1} \right\} < \infty,$$

where $p' = p/(p - 1)$ is the conjugate exponent of $p$. For $p = 1$, a non-negative, locally integrable function $w$ on $\mathbb{R}$ is called an $A_1(\mathbb{R})$ weight if, and only if, there exists a constant $C_w > 0$ such that

$$M(w)(x) \leq C_w w(x) \quad \text{for a.e. } x \in \mathbb{R}. \quad (2.3)$$

For $w \in A_1(\mathbb{R})$, one defines $[w]_{A_1(\mathbb{R})}$ to be the smallest positive constant $C_w$ such that condition (2.3) holds.

Let $p \in (1, \infty)$. A non-negative, locally integrable function $w$ on $\mathbb{R}^d$ is said to be a $d$-parameter $A_p^*(\mathbb{R}^d)$ weight if, and only if,

$$[w]_{A_p^*(\mathbb{R}^d)} := \sup_{I_n \text{ interval} \quad n=1,\ldots,d} \left\{ (w)_{I_1 \times \ldots \times I_d} \left( w^{1-p'} \right)_{I_1 \times \ldots \times I_d}^{p-1} \right\} < \infty.$$

For $p = 1$, a non-negative, locally integrable function $w$ on $\mathbb{R}^d$ is said to be a $d$-parameter $A_1^*(\mathbb{R}^d)$ weight if, and only if, there exists a constant $C_w > 0$ such that

$$M_S(w)(x_1, \ldots, x_d) \leq C_w w(x_1, \ldots, x_d) \quad \text{for a.e. } (x_1, \ldots, x_d) \in \mathbb{R}^d. \quad (2.4)$$

For $w \in A_1^*(\mathbb{R}^d)$, one defines $[w]_{A_1^*(\mathbb{R}^d)}$ to be the smallest positive constant $C_w$ satisfying (2.4).

In this paper, we shall mainly consider $d$-parameter weights of the form $w = w_1 \otimes \cdots \otimes w_d$. Note that in this case one has $[w]_{A_p^*(\mathbb{R}^d)} = \prod_{n=1}^d [w_n]_{A_p(\mathbb{R})}$ for $p \in (1, \infty)$. For basic properties of one-parameter and multi-parameter weights, we refer the reader to Chapter IV of [21].

For $1 \leq p < \infty$, if $T$ is a sublinear operator then we use the notation

$$\|T\|_{L^p(w) \to L^p(w)} := \sup_{\|f\|_{L^p(w)} = 1} \|T(f)\|_{L^p(w)},$$

\(\odot\) Springer
where
\[ \| g \|_{L^p(w)} := \left( \int_{\mathbb{R}^d} |g(x_1, \ldots, x_d)|^p w(x_1, \ldots, x_d) dx_1 \cdots dx_d \right)^{1/p}. \]

### 2.6 Khintchine’s Inequality

In several parts of this paper, we pass from square functions of the form \( \left( \sum_j |s_j|^2 \right)^{1/2} \) to corresponding families of functions \( \sum_j \pm s_j \) and vice versa by using a standard randomisation argument involving Khintchine’s inequality for powers \( p \in [1, 2) \).

Recall that given a probability space \( (\Omega, \mathcal{A}, P) \) and a countable set of indices \( F \), a sequence \( (r_n)_{n \in F} \) of independent random variables on \( (\Omega, \mathcal{A}, P) \) satisfying \( P(r_n = 1) = P(r_n = -1) = 1/2, n \in F \), is said to be a sequence of Rademacher functions on \( \Omega \) indexed by \( F \). Then, for every collection of complex numbers \( (a_{j_1}, \ldots, a_{j_d})_{j_1, \ldots, j_d \in F} \) with finitely many terms being non-zero, Khintchine’s inequality asserts that
\[
\left\| \sum_{j_1, \ldots, j_d \in F} a_{j_1} r_{j_1} \otimes \cdots \otimes r_{j_d} \right\|_{L^p(\Omega^d)} \sim \left( \sum_{j_1, \ldots, j_d \in F} |a_{j_1}, \ldots, a_{j_d}|^2 \right)^{1/2}
\]
for all \( 0 < p < \infty \), where the implied constants do not depend on \( (a_{j_1}, \ldots, a_{j_d})_{j_1, \ldots, j_d \in F} \).

In the special case where \( p \) is ‘close’ to \( 1^+ \), for instance when \( p \in [1, 2) \), the implied constants in (2.5) depend only on \( d \) and in particular they can be taken to be independent of \( p \in [1, 2) \); see Appendix D in [40].

### 3 Proof of Theorem 1

Let \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) be a lacunary sequence in \( \mathbb{N} \) with ratio \( \rho_\Lambda \in (1, 2) \). To prove Theorem 1, we shall first establish the weak-type inequality (1.6) for \( X = H^1(\mathbb{T}) \) and then use a Marcinkiewicz-type interpolation argument for analytic Hardy spaces on the torus.

As mentioned in the introduction, the proof of (1.6) for \( X = H^1(\mathbb{T}) \) can be obtained by using either the work of Tao and Wright [43] or a classical result of Coifman and Weiss [16] and more specifically, by using the argument of Coifman and Weiss that establishes [16, Theorem (1.20)]. As the former approach will be used in the proof of Theorem 2 in Sect. 4, we shall present here a proof of the desired weak-type inequality that uses arguments of [16].

To obtain the desired weak-type inequality following the latter method, we shall consider an appropriate sequence of ‘smoothed-out’ replacements \( (\widetilde{\Delta}^{(\Lambda)}_j)_{j \in \mathbb{N}_0} \) of \( (\Delta^{(\Lambda)}_j)_{j \in \mathbb{N}_0} \) satisfying
\[ \Delta^{(\Lambda)}_j \widetilde{\Delta}^{(\Lambda)}_j = \Delta^{(\Lambda)}_j. \]
The sequence of operators \((\widetilde{\Delta}_{j})_{j \in \mathbb{N}_0}\) is defined as follows. For \(j = 0\), let \(\widetilde{\Delta}_{0}\) denote the multiplier operator whose symbol \(m_{0}^{(\Lambda)}: \mathbb{Z} \to \mathbb{R}\) is such that

- \(\text{supp}(m_{0}^{(\Lambda)}) = \{-\lambda_{1} + 1, \ldots, \lambda_{1} - 1\}\).
- \(m_{0}^{(\Lambda)}(n) = 1\) for all \(n \in \{-\lambda_{0}, \ldots, \lambda_{0}\}\).
- \(m_{0}^{(\Lambda)}\) is ‘affine’ in \([-\lambda_{1}, \ldots, -\lambda_{0}]\) and in \([\lambda_{0}, \ldots, \lambda_{1}]\).

For \(j \in \mathbb{N}\), define \(\widetilde{\Delta}_{j}\) to be the multiplier operator whose associated multiplier \(m_{j}^{(\Lambda)}: \mathbb{Z} \to \mathbb{R}\) is even and satisfies:

- \(\text{supp}(m_{j}^{(\Lambda)}) = \{\lambda_{j-2} + 1, \ldots, \lambda_{j+1} - 1\}\).
- \(m_{j}^{(\Lambda)}(n) = 1\) for all \(n \in \{\lambda_{j-1}, \ldots, \lambda_{j}\}\).
- \(m_{j}^{(\Lambda)}\) is ‘affine’ in \([\lambda_{j-2}, \ldots, \lambda_{j-1}]\) and in \([\lambda_{j}, \ldots, \lambda_{j+1}]\).

Here, in the case where \(j = 1\), we make the convention that \(\lambda_{-1} := \lfloor \lambda_{0}/\rho^{\Lambda} \rfloor\).

The following lemma is a consequence of the argument of Coifman and Weiss establishing [16, Theorem (1.20)].

**Lemma 3** Let \(\Lambda = (\lambda_{j})_{j \in \mathbb{N}_0}\) be a lacunary sequence in \(\mathbb{N}\) with ratio \(\rho_{\Lambda} \in (1, 2)\).

If \((\widetilde{\Delta}_{j})_{j \in \mathbb{N}_0}\) is defined as above and \((\Omega, \mathcal{A}, \mathbb{P})\) is a probability space, for \(\omega \in \Omega\), consider the operator \(\widetilde{T}_{\omega}^{(\Lambda)}\) given by

\[
\widetilde{T}_{\omega}^{(\Lambda)} := \sum_{j \in \mathbb{N}_0} r_{j}(\omega)\widetilde{\Delta}_{j}^{(\Lambda)},
\]

where \((r_{j})_{j \in \mathbb{N}_0}\) denotes the set of Rademacher functions on \(\Omega\) indexed by \(\mathbb{N}_0\). Then, there exists an absolute constant \(A_{0} > 0\) such that

\[
\left\| \widetilde{T}_{\omega}^{(\Lambda)}(f) \right\|_{L^{1}(\mathbb{T})} \leq \frac{A_{0}}{(\rho_{\Lambda} - 1)^{1/2}} \| f \|_{H^{1}(\mathbb{T})},
\]

for every choice of \(\omega \in \Omega\).

**Proof** Let \(m_{\omega}^{(\Lambda)}\) denote the symbol of the operator \(\widetilde{T}_{\omega}^{(\Lambda)}\) in the statement of the lemma, namely

\[
m_{\omega}^{(\Lambda)} := \sum_{j \in \mathbb{N}_0} r_{j}(\omega)m_{j}^{(\Lambda)},
\]

where \(m_{j}^{(\Lambda)}\) are as above, \(j \in \mathbb{N}_0\). Our first task is to show that \(m_{\omega}^{(\Lambda)}\) satisfies the following ‘Mikhlin-type’ condition

\[
\sup_{n \in \mathbb{Z}} \left\{ |n||m_{\omega}^{(\Lambda)}(n + 1) - m_{\omega}^{(\Lambda)}(n)| \right\} \leq C_{0}(\rho_{\Lambda} - 1)^{-1},
\]

\(\square\) Springer
where $C_0 > 0$ is an absolute constant, independent of $\omega$ and $\Lambda$. The verification of (3.2) is elementary. Indeed, to show (3.2), note that for every $n \in \mathbb{Z}$ there exist at most 3 non-zero terms in the sum

$$m_\omega^{(\Lambda)}(n) = \sum_{j \in \mathbb{N}_0} r_j(\omega)m_j^{(\Lambda)}(n)$$

and so, it suffices to show that for every $j \in \mathbb{N}_0$ one has

$$\delta_j(n) := |m_j^{(\Lambda)}(n + 1) - m_j^{(\Lambda)}(n)| \lesssim \frac{1}{|n|} \frac{1}{(\rho_\Lambda - 1)}$$

(3.3)

for all $n \in \mathbb{Z} \setminus \{0\}$, where the implied constant is independent of $n$ and $\Lambda$. To show (3.3), fix a $j \in \mathbb{N}_0$ and take an $n \in \text{supp}(m_j^{(\Lambda)})$. We may assume that $j \in \mathbb{N}$, as the case $j = 0$ is treated similarly and gives the same bounds. Suppose first that $n \in \{-\lambda_{j+1}, \ldots, -\lambda_{j-1}\} \cup \{\lambda_{j-1}, \ldots, \lambda_{j+1}\}$. Observe that in the subcase where $\lambda_{j-1} \leq |n| < \lambda_j$ one has $\delta_j(n) = 0$ and so, (3.3) trivially holds. If we now assume that $\lambda_j \leq |n| \leq \lambda_{j+1}$, then one has

$$\delta_j(n) = \frac{1}{\lambda_{j+1} - \lambda_j} \leq \frac{1}{\lambda_{j+1}(1 - \rho_\Lambda^{-1})} \leq \frac{1}{|n|(1 - \rho_\Lambda^{-1})} \leq \frac{2}{|n|}$$

as desired. The case where $n \in \{-\lambda_{j-1}, \ldots, -\lambda_{j-2}\} \cup \{\lambda_{j-2}, \ldots, \lambda_{j-1}\}$ is handled similarly and also gives $|n|\delta_j(n) \leq 2(\rho_\Lambda - 1)^{-1}$. Therefore, (3.3) holds and so, (3.2) is valid with $C_0 = 6$.

Consider now an arbitrary non-constant atom $a$ in $H^1(\mathbb{T})$. Then, the proof of [16, Theorem (1.20)], together with the estimate (3.2), yields that

$$\|\tilde{T}_\omega^{(\Lambda)}(a)\|_{L^1(\mathbb{T})} \lesssim \|m_\omega^{(\Lambda)}\|_{\ell^\infty(\mathbb{Z})} + \|m_\omega^{(\Lambda)}\|_{\ell^\infty(\mathbb{Z})}^{1/2}(\rho_\Lambda - 1)^{-1/2},$$

(3.4)

where the implied constant does not depend on $\tilde{T}_\omega^{(\Lambda)}$ and $a$. Indeed, notice that it follows from [16, (1.16)] that

$$\int_{\mathbb{T}} |\tilde{T}_\omega^{(\Lambda)}(a)(x)|dx \leq 3\pi \left( \int_{\mathbb{T}} |\tilde{T}_\omega^{(\Lambda)}(a)(x)|^2 dx \right)^{1/4} \left( \int_{\mathbb{T}} |\tilde{T}_\omega^{(\Lambda)}(a)(x)|^2 |1 - e^{ix}|^2 dx \right)^{1/4}$$

and hence, by using (3.3) and arguing exactly as on pp. 578–579 in [16], one deduces that

$$\left( \int_{\mathbb{T}} |\tilde{T}_\omega^{(\Lambda)}(a)(x)|^2 dx \right)^{1/4} \left( \int_{\mathbb{T}} |\tilde{T}_\omega^{(\Lambda)}(a)(x)|^2 |1 - e^{ix}|^2 dx \right)^{1/4} \lesssim \|m_\omega^{(\Lambda)}\|_{\ell^\infty(\mathbb{Z})}$$

$$+ \|m_\omega^{(\Lambda)}\|_{\ell^\infty(\mathbb{Z})}^{1/2} \|a\|_{L^2(\mathbb{T})}^{1/2} \left( \frac{1}{(\rho_\Lambda - 1)^2} \sum_{|n| \leq |a|} \|a\|_{L^2(\mathbb{T})}^{-4} + \frac{1}{(\rho_\Lambda - 1)^2} \sum_{|n| > |a|} \|a\|_{L^2(\mathbb{T})}^{-4} \right)^{1/4}$$

$\copyright$ Springer
and so, (3.4) follows. Note that since \( \| m_\omega^{(A)} \|_{L^\infty(\mathbb{Z})} \leq 3 \), we deduce from (3.4) that there exists an absolute constant \( D_0 > 0 \) such that

\[
\| \tilde{T}_\omega^{(A)}(a) \|_{L^1(T)} \leq D_0 (\rho_\Lambda - 1)^{-1/2}
\]

for any non-constant atom \( a \) in \( H^1(T) \). Moreover, observe that the constant atom \( a_0 = \chi_T \) trivially satisfies (3.5), since

\[
\| \tilde{T}_\omega^{(A)}(a_0) \|_{L^1(T)} = \left| m_\omega^{(A)}(0) \widehat{a_0}(0) \right| \leq D'_0 (\rho_\Lambda - 1)^{-1/2},
\]

where \( D'_0 := \max\{D_0, 3\} \). Therefore, (3.5) holds for all atoms in \( H^1(T) \) and hence, by arguing as e.g. on pp. 129–130 in [23], we deduce that (3.5) holds in the whole of \( H^1(T) \) with \( A_0 = c_1 D'_0 \), \( c_1 \) being the constant in (2.1).

Having established Lemma 3, we are now ready to prove (1.6) for \( X = H^1(T) \). Note that by using (1.6) for \( X = H^1(T) \) combined with the fact that \( \| g \|_{H^1(T)} = 2 \| g \|_{L^1(T)} \) for each analytic trigonometric polynomial \( g \) and the density of analytic trigonometric polynomials in \( (H^1_A(T), \| \cdot \|_{L^1(T)}) \), one deduces that there exists an absolute constant \( M_0 > 0 \) such that

\[
\| S^{(A)}(g) \|_{L^1,\infty(T)} \leq M_0 \frac{1}{(\rho_\Lambda - 1)^{1/2}} \| g \|_{L^1(T)} \quad (g \in H^1_A(T)).
\]

Now, in order to prove (1.6) for \( X = H^1(T) \), fix an arbitrary trigonometric polynomial \( f \) and define \( (h_j)_{j \in \mathbb{N}_0} \) by \( h_j := \tilde{\Delta}_j^{(A)}(f) \), where \( \tilde{\Delta}_j^{(A)} \) are the ‘smoothed-out’ versions of \( \Delta_j^{(A)} \), introduced above. It follows from Corollary 2.13 on p. 488 in [21] and the definition of \( (h_j)_{j \in \mathbb{N}_0} \) that

\[
\| S^{(A)}(f) \|_{L^1,\infty(T)} \lesssim \left\| \left( \sum_{j \in \mathbb{N}_0} |h_j|^2 \right)^{1/2} \right\|_{L^1(T)},
\]

where the implied constant does not depend on \( f \) and \( \Lambda \). If we fix a probability space \( (\Omega, \mathcal{A}, \mathbb{P}) \), observe that, by using the definition of \( (h_j)_{j \in \mathbb{N}_0} \) together with Khintchine’s inequality (2.5) and Fubini’s theorem, one has

\[
\left\| \left( \sum_{j \in \mathbb{N}_0} |h_j|^2 \right)^{1/2} \right\|_{L^1(T)} \lesssim \int_{\Omega} \| \tilde{T}_\omega^{(A)}(f) \|_{L^1(T)} d\mathbb{P}(\omega),
\]

where the implied constant is independent of \( f \) and \( \Lambda \). Here, \( \tilde{T}_\omega^{(A)} \) denotes the multiplier operator in the statement of Lemma 3. Hence, by using the last estimate, (3.1), and (3.7), we obtain (1.6) for \( X = H^1(T) \).

We shall now employ the following result, which is due to Kislyakov and Xu [26]. See also [9, Proposition 1.6] and [34, Lemma 7.4.2].
Lemma 4 ([26]) If $f \in H^1_A(\mathbb{T})$ and $\alpha > 0$, then there exist functions $g_\alpha \in H^1_A(\mathbb{T})$ and $h_\alpha \in H^\infty_A(\mathbb{T})$ such that $f = g_\alpha + h_\alpha$ and

- $\|g_\alpha\|_{L^1(\mathbb{T})} \leq C \int_{\{||f|| > \alpha\}} |f(x)| dx$
- $|h_\alpha(x)| \leq C \alpha \min\{\alpha |f(x)|^{-1}, \alpha^{-1} |f(x)|\}$ for a.e. $x \in \mathbb{T}$,

where the constant $C > 0$ does not depend on $f$ and $\alpha$.

To complete the proof of Theorem 1, one argues as in [7]. More precisely, fix a $p \in (1, 2)$ and take an arbitrary $f \in H^p_A(\mathbb{T})$ with $\|f\|_{L^p(\mathbb{T})} = 1$. Assume first that $p$ is ‘close’ to $1^+$, for instance, suppose that $p \in (1, 3/2]$. Since $f \in H^p_A(\mathbb{T}) \subseteq H^1_A(\mathbb{T})$, by using Lemma 4, we may write

$$
\|S^{(A)}(f)\|^p_{L^p(\mathbb{T})} = (2\pi)^{-1} \int_0^\infty \alpha^{p-1} \left| \left\{ x \in \mathbb{T} : S^{(A)}(f)(x) > \alpha \right\} \right| d\alpha \leq I_1 + I_2,
$$

where

$$
I_1 := (2\pi)^{-1} p \int_0^\infty \alpha^{p-1} \left| \left\{ x \in \mathbb{T} : S^{(A)}(g_\alpha)(x) > \alpha/2 \right\} \right| d\alpha
$$

and

$$
I_2 := (2\pi)^{-1} p \int_0^\infty \alpha^{p-1} \left| \left\{ x \in \mathbb{T} : S^{(A)}(h_\alpha)(x) > \alpha/2 \right\} \right| d\alpha.
$$

To handle $I_1$, we use (3.6), the properties of $g_\alpha \in H^1_A(\mathbb{T})$, Fubini’s theorem, and the assumption that $\|f\|_{L^p(\mathbb{T})} = 1$ as follows,

$$
I_1 \leq (2\pi)^{-1} 2p M_0 (\rho_A - 1)^{-1/2} \int_0^\infty \alpha^{p-2} \left[ \int_{\mathbb{T}} |g_\alpha(x)| dx \right] d\alpha
\leq \pi^{-1} p M_0 C (\rho_A - 1)^{-1/2} \int_0^\infty \alpha^{p-2} \left[ \int_{\{||f|| > \alpha\}} |f(x)| dx \right] d\alpha
\leq C_0 (\rho_A - 1)^{-1/2} \frac{1}{p - 1},
$$

where $C_0 = 4 M_0 C$ with $M_0$ and $C$ being the constants in (3.6) and in Lemma 4, respectively. To handle $I_2$, we first use the fact that $\|S^{(A)}\|_{L^2(\mathbb{T}) \to L^2(\mathbb{T})} = 1$ and get

$$
I_2 \leq (2\pi)^{-1} p \int_0^\infty \alpha^{p-1} \left| \left\{ x \in \mathbb{T} : S^{(A)}(h_\alpha)(x) > \alpha/2 \right\} \right| d\alpha
\leq (2\pi)^{-1} 4p \int_0^\infty \alpha^{p-3} \left[ \int_{\mathbb{T}} |h_\alpha(x)|^2 dx \right] d\alpha
$$

\[ Springer \]
and then, arguing as e.g. in the proof of [34, Theorem 7.4.1], we write $I_2 \leq I'_2 + I''_2$, where

$$I'_2 := 2\pi^{-1} C \int_0^\infty \alpha^{p-3} \left[ \int_{|f| \leq \alpha} |f(x)|^2 \right] \, d\alpha$$

and

$$I''_2 := 2\pi^{-1} C \int_0^\infty \alpha^{p+1} \left[ \int_{|f| > \alpha} |f(x)|^{-2} \right] \, d\alpha,$$

with $C > 0$ being the constant in Lemma 4. Hence, by using Fubini’s theorem and the assumption that $\|f\|_{L^p(T)} = 1$, we have

$$I'_2 \leq \frac{C'}{2 - p}$$

and

$$I''_2 \leq \frac{C'}{p + 2},$$

where $C' > 0$ is an absolute constant. Putting all the estimates together, we obtain

$$\|S^{(\Lambda)}(f)\|_{L^p(T)}^p \leq C_0 (\rho_\Lambda - 1)^{-1/2} \frac{1}{p - 1} + \frac{C'}{2 - p} + \frac{C'}{p + 2}$$

and since $p \in (1, 3/2]$, we deduce that

$$\|S^{(\Lambda)}(f)\|_{L^p(T)} \lesssim \frac{1}{p - 1} (\rho_\Lambda - 1)^{-1/2},$$

where the implied constant does not depend on $f$, $p$, and $\Lambda$.

We remark that (1.3) also holds for $p \in (3/2, 2)$. To see this, observe that [13, Theorem 2] implies that, e.g. $\|S^{(\Lambda)}\|_{L^3(T) \rightarrow L^3(T)} \leq C$, where $C > 0$ does not depend on the lacunary sequence $\Lambda$. Hence, arguing as in the case where $p \in (1, 3/2]$, namely by using Lemma 4 and, in particular, by interpolating between (3.6) and the $L^3(T) \rightarrow L^3(T)$ bound mentioned above, we deduce that (1.3) is also valid for $p \in (3/2, 2)$. Therefore, the proof of Theorem 1 is complete.

### 3.1 Optimality of Theorem 1

In this subsection, it is shown that the exponent $r = 1/2$ in $(\rho_\Lambda - 1)^{-1/2}$ in (1.3) is optimal in the sense that for every $\lambda$ ‘close’ to $1^+$ one can exhibit a lacunary sequence $\Lambda$ with ratio $\rho_\Lambda \in [\lambda, \lambda^2)$ such that (1.4) holds. To this end, the idea is to consider
lacunary sequences $\Lambda$ whose terms essentially behave like $\lambda^j q_j (\lambda - 1)^{-1}$ for all $j \in \mathbb{N}_0$, where $q_j \sim 1$, $j \in \mathbb{N}_0$.

To be more precise, given a $\lambda > 1$ with $\lambda^2 < 2$, we shall define $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ inductively as follows. Set

$$\lambda_0 := \left\lceil \frac{1}{\lambda - 1} \right\rceil \quad (3.8)$$

and for $j \in \mathbb{N}$ define

$$\lambda_j := \lceil \lambda \cdot \lambda_{j-1} \rceil. \quad (3.9)$$

We claim that one has

$$\lambda \leq \frac{\lambda_j}{\lambda_{j-1}} < \lambda^2 \quad \text{for all } j \in \mathbb{N}. \quad (3.10)$$

Indeed, for the left hand-side of (3.10), note that for each $j \in \mathbb{N}$ one has

$$\frac{\lambda_j}{\lambda_{j-1}} \geq \frac{\lambda \cdot \lambda_{j-1}}{\lambda_{j-1}} = \lambda.$$

Note that this implies that $\Lambda$ is lacunary with ratio $\rho_\Lambda \geq \lambda$ and hence, strictly increasing. To prove the right-hand side of (3.10), we use (3.9) and the previous step,

$$\frac{\lambda_j}{\lambda_{j-1}} < \frac{\lambda \cdot \lambda_{j-1} + 1}{\lambda_{j-1}} = \lambda + \frac{1}{\lambda_{j-1}} < \lambda + \frac{1}{\lambda_0}.$$

Hence, it suffices to show that

$$\lambda + \frac{1}{\lambda_0} < \lambda^2,$$

which is equivalent to

$$\lambda_0 > \frac{1}{\lambda(\lambda - 1)}.$$

The last inequality clearly holds, as (3.8) implies that

$$\lambda_0 \geq \frac{1}{\lambda - 1} > \frac{1}{\lambda(\lambda - 1)}.$$

We thus deduce that (3.10) holds for all $j \in \mathbb{N}$.

Having constructed $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ as above, consider the corresponding square function $S^{(\Lambda)}$. Next, given a $p \in (1, 2)$, let $N \in \mathbb{N}$ be such that

$$N := \left\lceil \frac{2}{\lambda - 1} \cdot e^{1/(p-1)} \right\rceil \quad (3.11)$$
and observe that

\[ N^{(p-1)/p} \sim \left( \frac{1}{\lambda - 1} \right)^{(p-1)/p}. \quad (3.12) \]

Consider now the de la Vallée Poussin kernel \( V_N \) of order \( N \), namely

\[ V_N := 2K_{2N+1} - K_N, \]

\( K_n \) being the Fejér kernel of order \( n \); \( K_n(x) := \sum_{|j|\leq n} (1 - |j|/(n+1))e^{ijx}, \ x \in \mathbb{T} \). As in [7], consider the analytic trigonometric polynomial \( f_N \) given by

\[ f_N(x) := e^{i(2N+1)x} V_N(x), \ x \in \mathbb{T}. \]

Using (3.12), one has

\[ \|f_N\|_{L^p(\mathbb{T})} \lesssim \left( \frac{1}{\lambda - 1} \right)^{(p-1)/p}. \quad (3.13) \]

Indeed, arguing as on p. 424 in [32], observe that \( \|f_N\|_{L^1(\mathbb{T})} \lesssim 1 \) and \( \|f_N\|_{L^\infty(\mathbb{T})} \lesssim N \) and hence, interpolation implies that \( \|f_N\|_{L^p(\mathbb{T})} \lesssim N^{1-1/p} \). Therefore, (3.13) follows from (3.12).

Next, we claim that the set \( A_{\lambda N} \) := \( \{ j \in \mathbb{N}_0 : N \leq \lambda_j \leq 2N \} \) is non-empty and has cardinality

\[ \#(A_{\lambda N}) \sim (\lambda - 1)^{-1} \sim (\rho - 1)^{-1}. \quad (3.14) \]

To prove that \( A_{\lambda N} \) is non-empty, observe that it follows from (3.8) and (3.11) that

\[ \lambda_0 < \frac{2}{\lambda - 1} \leq N \]

and hence, there exists a \( k_0 \in \mathbb{N} \) such that

\[ \lambda_{k_0-1} < N \leq \lambda_{k_0}. \]

Using now the right-hand side of (3.10), we obtain

\[ \lambda_{k_0} < \lambda^2 \lambda_{k_0-1} < \lambda^2 N < 2N. \]

It thus follows that \( k_0 \in A_{\lambda N} \) and so, \( A_{\lambda N} \) is a non-empty set of indices. In order to prove (3.14), note that if we set \( k := \#(A_{\lambda N}) \) and \( k_0 \in \mathbb{N} \) is as above, then the definition of \( A_{\lambda N} \) and the left-hand side of (3.10) give

\[ 2N \geq \lambda_{k_0+k-1} \geq \lambda^{k-1} \lambda_{k_0} \geq \lambda^{k-1} N \]

\( \Box \) Springer
and so, \( \lambda^{k-1} \leq 2 \). Hence, \( k \leq 1 + \log_\lambda 2 \sim [\log \lambda]^{-1} \) and since \([\log \lambda]^{-1} \sim (\lambda - 1)^{-1}\), we get the upper estimate

\[
k \lesssim (\lambda - 1)^{-1}.
\] (3.15)

By the definitions of \( A_N^{(\Lambda)} \), \( k_0 \), \( k \), and the right-hand side of (3.10), we obtain

\[
2N \leq \lambda^{k_0+k+1} \leq \lambda^{2(k+1)} \lambda^{k_0-1} < \lambda^{2(k+1)N}
\]

and so, \((\lambda - 1)^{-1} \sim \log_\lambda 2 < 2(k + 1)\). Hence, we also get the lower estimate

\[
k \gtrsim (\lambda - 1)^{-1}
\] (3.16)

and therefore, the proof of (3.14) is complete in view of (3.15) and (3.16).

Going now back to the proof of (1.4), observe that, thanks to the definition of \( f_N \), one has

\[
\Delta_j^{(\Lambda)}(f_N)(x) = \sum_{n=\lambda_j-1}^{\lambda_j-1} e^{inx}
\] (3.17)

for all \( j \in A_N^{(\Lambda)} \). Therefore, by using (3.17), (3.10), and (3.11), one deduces that

\[
\|\Delta_j^{(\Lambda)}(f_N)\|_{L^1(T)} \sim \log(\lambda_j - \lambda_{j-1}) \geq \log(N(\lambda - 1)) \sim \frac{1}{p - 1}
\]

for all \( j \in A_N^{(\Lambda)} \) with \( j > k_0 + 1 \), \( k_0 \) being as above. Hence, arguing as in [13], by using Minkowski’s inequality together with the last estimate and (3.14), we get

\[
\|S^{(\Lambda)}(f_N)\|_{L^p(T)} \gtrsim \left( \sum_{j \in A_N^{(\Lambda)}} \|\Delta_j^{(\Lambda)}(f_N)\|^2_{L^1(T)} \right)^{1/2} \gtrsim \left( \sum_{j \in A_N^{(\Lambda)}} \|\Delta_j^{(\Lambda)}(f_N)\|^2_{L^1(T)} \right)^{1/2} \gtrsim (\#(A_N^{(\Lambda)})(p-1)^{-2})^{1/2} \sim (p-1)^{-1}(\rho_{\Lambda} - 1)^{-1/2}.
\]

It thus follows from the last estimate combined with (3.13) that

\[
(p-1) \sup_{\|f\|_{L^p(T)}=1} \|S^{(\Lambda)}(f)\|_{L^p(T)} \gtrsim (\rho_{\Lambda} - 1)^{-1/2+(p-1)/p}
\]

and so, by taking \( p \to 1^+ \), we obtain (1.4).
Remark 5 Let \( p \in (1, 2) \) be fixed. Observe that if one takes \( \lambda \in (1, 2) \) such that \( (\lambda - 1)/(p - 1) \sim 1 \) (e.g. for \( \lambda = p^{1/2} \)) and defines \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) as above, then the previous argument shows that \( (\rho - 1)/(p - 1) \sim 1 \) and

\[
\sup_{\|f\|_{L_p(T)} = 1} \left\| S^{(\Lambda)}(f) \right\|_{L_p(T)} \geq (\lambda - 1)^{-3/2}\cdot (\lambda - 1)^{(p-1)/p} \sim (\lambda - 1)^{-3/2} \sim (\rho - 1)^{-3/2},
\]

which is the lower estimate mentioned in Remark (i) in [35, Sect. 3].

3.1.1 Some Further Remarks Concerning Sharpness

In view of the construction presented above and the fact that \( \| S^{(\Lambda)} \|_{L^2(T) \to L^2(T)} = 1 \), it would seem natural to expect that there exists an absolute constant \( C_0 > 0 \) such that for every lacunary sequence \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) in \( \mathbb{N} \) with ratio \( \rho_\Lambda \in (1, 2) \) one has

\[
\sup_{\|f\|_{L_p(T)} = 1} \left\| S^{(\Lambda_0)}(f) \right\|_{L_p(T)} \leq \frac{C_0}{p - 1} (\rho_\Lambda - 1)^{-1/2 + (p-1)/p}
\]

(3.18)

for all \( p \in (1, 2) \).

At this point, it is worth mentioning that for every rational number \( \lambda \) ‘close’ to \( 1^+ \), one can exhibit a lacunary sequence \( \Lambda_0 = (\lambda_j^{(0)})_{j \in \mathbb{N}_0} \) with ratio \( \rho_{\Lambda_0} = \lambda \) such that

\[
\sup_{\|f\|_{L_p(T)} = 1} \left\| S^{(\Lambda_0)}(f) \right\|_{L_p(T)} \sim (p - 1)^{-1} \quad \text{for all } p \in (1, 2).
\]

(3.19)

Indeed, if \( p, q \in \mathbb{N} \) are such that \( \lambda = p/q \), take \( \lambda_0^{(0)} := q, \lambda_1^{(0)} := p \) and for \( j \geq 2 \) define \( \lambda_j^{(0)} := 2\lambda_{j-1}^{(0)} \). Let \( (\Omega, \mathcal{A}, \mathbb{P}) \) be a probability space. Note that there exists an absolute constant \( A_0 > 0 \) such that for every choice of \( \omega \in \Omega \), \( T_{m_\omega} := \sum_{n \in \mathbb{N}_0} f_n(\omega) \Delta_n^{(\Lambda_0)}(\cdot) \) is a Marcinkiewicz multiplier operator with corresponding symbol \( m_\omega \) satisfying

\[
\| m_\omega \|_{\ell^\infty(\mathbb{Z})} + \sup_{N \in \mathbb{N}} \left\{ \sum_{2^{N-1} \leq |n| \leq 2^{N-1}} |m_\omega(n + 1) - m_\omega(n)| \right\} \leq A_0.
\]

(3.20)

Hence, (3.19) is obtained by combining (3.20) with [7, Theorem 1], and then using (2.5).

Similarly, one can show that (3.19) holds for every lacunary sequence \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) with ratio \( \rho_\Lambda \geq 2 \).
3.2 A Classical Inequality of Paley

A classical theorem of Paley [33] asserts that if $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ is a lacunary sequence in $\mathbb{N}$, then for every $f \in H^1_A(T)$ the sequence $(\hat{f}(\lambda_j))_{j \in \mathbb{N}_0}$ is square summable. Moreover, Paley’s argument in [33] yields that if $\Lambda$ is a lacunary sequence in $\mathbb{N}$ with ratio $\rho/\Lambda_n \in (1, 2)$ for $n \in \{1, \ldots, d\}$, then

$$\left( \sum_{j \in \mathbb{N}_0} |\hat{f}(\lambda_j)|^2 \right)^{1/2} \lesssim (\rho - 1)^{-1/2} \|f\|_{L^1(T)} \quad (f \in H^1_A(T)). \quad (3.21)$$

Paley’s inequality was extended by Oberlin’s in [31] using Stein’s theorem [38,39]; see Corollary on p. 45 in [31]. Notice that by using Lemma 3, iteration and multidimensional Khintchine’s inequality (2.5), one recovers Oberlin’s extension of Paley’s inequality, namely if $\Lambda_n = (\lambda^{(n)}_j)_{j \in \mathbb{N}_0}$ is a lacunary sequence in $\mathbb{N}$ with ratio $\rho/\Lambda_n \in (1, 2)$ for $n \in \{1, \ldots, d\}$, then

$$\left( \sum_{j_1, \ldots, j_d \in \mathbb{N}_0} |\hat{f}\left(\lambda^{(1)}_{j_1}, \ldots, \lambda^{(d)}_{j_d}\right)|^2 \right)^{1/2} \lesssim_d \left[ \prod_{n=1}^d (\rho - 1)^{-1/2} \right] \|f\|_{L^1(T^d)} \quad \text{(3.22)}$$

for all $f \in H^1_A(T^d)$. Furthermore, an adaptation of the argument presented in the previous subsection shows that the exponents $r = 1/2$ in $\prod_{n=1}^d (\rho - 1)^{-1/2}$ in (3.22) cannot be improved in general.

3.3 An Optimal Version of a Theorem Due to Zygmund

By using (3.6) and Lemma 4, one obtains the following version of an inequality due to Zygmund (see [44, Theorem 8]),

$$\|S^{(\Lambda)}(f)\|_{L^1(T)} \leq C (\rho - 1)^{-1/2} \|f\|_{L \log L(T)} \quad (f \in H^1_A(T)). \quad (3.23)$$

By using the argument presented in Sect. 3.1, one can show that the exponent $r = 1/2$ in $(\rho - 1)^{-1/2}$ in (3.23) cannot be improved in general. We remark that (3.23) may also be regarded as a direct consequence of (1.3) via extrapolation for analytic Hardy spaces; see [5,6].

4 Proof of Theorem 2

As mentioned in the introduction, the first step in the proof of Theorem 2 is to establish the weak-type inequality (1.6) for $X = L \log^{1/2} L(T)$ and this inequality will be obtained by using the work of Tao and Wright on the endpoint behaviour of Marcinkiewicz multiplier operators acting on functions defined over the real line [43].
To be more precise, let $\eta$ be a fixed Schwartz function that is even, supported in $(-8, -1/8) \cup (1/8, 8)$ and such that $\eta\mid_{[1/4, 1]} \equiv 1$. For $j \in \mathbb{N}$, set $\eta_j(\xi) := \eta(2^{-j}\xi)$ for $\xi \in \mathbb{R}$ and denote by $\tilde{\Delta}_j$ the periodic multiplier operator whose symbol is given by $\eta_j|_\mathbb{Z}$, i.e. $\tilde{\Delta}_j = T_{\eta_j}|_\mathbb{Z}$. We shall also consider the sequence of functions $(\phi_j)_{j \in \mathbb{N}}$ given by

$$
\phi_j(x) := 2^j \left[1 + 2^{2j} \sin^2(x/2)\right]^{-3/4}, \quad x \in \mathbb{T}.
$$

By arguing exactly as on pp. 547–549 in [43] one deduces that [43, Proposition 9.1] implies that for every $f \in L \log^{1/2} L(\mathbb{T})$ there exists a sequence $(F_j)_{j \in \mathbb{N}}$ of non-negative functions such that for every $j \in \mathbb{N}$ one has

$$
|\tilde{\Delta}_j(f)(x)| \lesssim (F_j * \phi_j)(x) \quad \text{for all } x \in \mathbb{T}
$$

(4.1)

and

$$
\left\| \left( \sum_{j \in \mathbb{N}} |F_j|^2 \right)^{1/2} \right\|_{L^1(\mathbb{T})} \lesssim 1 + \int_\mathbb{T} |f(x)| \log^{1/2}(e + |f(x)|)dx.
$$

(4.2)

We omit the details. Notice that (4.2) can be regarded as a periodic analogue of [43, Proposition 4.1].

Fix now a lacunary sequence $\Lambda = (\lambda_k)_{k \in \mathbb{N}_0}$ of positive integers with $\rho_\Lambda \in (1, 2)$. Note that it follows from the mapping properties of the periodic Hilbert transform that for every $a, b \in \mathbb{R}$ such that $a < b$, the multiplier operator $T_{X[a, b]}$ is of weak-type $(1, 1)$ and bounded on $L^p(\mathbb{T})$ for all $1 < p < \infty$ with corresponding operator norm bounds that are independent of $a, b$. We may thus assume, without loss of generality, that $\lambda_0 \geq 8$.

For technical reasons, in order to suitably adapt the relevant arguments of [43] to the periodic setting and prove that $S^{(\Lambda)}$ satisfies (1.6) for $X = L \log^{1/2} L(\mathbb{T})$, it would be more convenient to work with $S^{(\tilde{\Lambda})}$, where $\tilde{\Lambda}$ is a strictly increasing sequence in $\mathbb{N}$, which is associated to $\Lambda$ and satisfies the properties of the following lemma.

Lemma 6 Let $\Lambda = (\lambda_k)_{k \in \mathbb{N}_0}$ be a lacunary sequence in $\mathbb{N}$ with $\rho_\Lambda \in (1, 2)$ and $\lambda_0 \geq 8$.

There exists a $\Lambda' \subseteq \mathbb{N}$ such that if we regard $\tilde{\Lambda} := \Lambda \cup \Lambda' \cup (2^{j+3})_{j \in \mathbb{N}_0}$ as a strictly increasing sequence in $\mathbb{N}$ and write $\tilde{\Lambda} = (\lambda_k)_{k \in \mathbb{N}_0}$, then $\lambda_0 = 8$ and, moreover, $\tilde{\Lambda}$ has the following properties:

1) For every $k \in \mathbb{N}$ there exists a positive integer $j_k \geq 4$ such that

$$
[\tilde{\lambda}_{k-1}, \tilde{\lambda}_k) \subseteq [2^{j_k-1}, 2^{j_k})
$$

and $\tilde{\lambda}_k - \tilde{\lambda}_{k-1} \leq 2^{j_k-3}$.

2) For all $N \in \mathbb{N}$, one has

$$
\#(\tilde{\Lambda} \cap \{2^{N-1}, \ldots, 2^N\}) \leq 9(\#(\Lambda \cap \{2^{N-1}, \ldots, 2^N\}) + 2).
$$
The desired construction is elementary. First of all, note that if we regard the set $\Lambda_d := \Lambda \cup (2^{j+3})_{j \in \mathbb{N}_0}$ as a strictly increasing sequence in $\mathbb{N}$ and write $\Lambda_d = (\lambda_k^{(d)})_{k \in \mathbb{N}_0}$, then $\lambda_0^{(d)} = \min\{\lambda_0, 8\} = 8$ and for every $k \in \mathbb{N}$ there exists a positive integer $j_k \geq 4$ such that $I_k^{(d)} := [\lambda_k^{(d)} - 1, \lambda_k^{(d)}] \subseteq [2^{j_k-1}, 2^{j_k}]$.

We shall now construct $\Lambda' = \bigcup_{k \in \mathbb{N}_0} \Lambda'_k$, where the sets $\Lambda'_k \subseteq \mathbb{N}$ are defined inductively as follows.

- For $k = 0$, define $\Lambda'_0 := \{\lambda_0^{(d)}\}$.
- For $k \in \mathbb{N}$, let $j_k$ and $I_k^{(d)}$ be as above.

**Case 1** If $|I_k^{(d)}| \leq 2^{j_k-3}$ then $\Lambda'$ contains no terms between $\lambda_k^{(d)}$ and $\lambda_k^{(d)}$, namely we set $\Lambda'_k := \emptyset$.

**Case 2** If $|I_k^{(d)}| > 2^{j_k-3}$ then, since $I_k^{(d)} \subseteq [2^{j_k-1}, 2^{j_k})$, there exist positive integers $a_k^{(1)} \leq a_k^{(2)} \leq \cdots \leq a_k^{(8)}$, suitably chosen, such that the intervals $[\lambda_k^{(d)} - 1, a_k^{(1)}], [a_k^{(1)}, a_k^{(2)}], \ldots, [a_k^{(7)}, a_k^{(8)}]$, and $[a_k^{(8)}, \lambda_k^{(d)}]$ have lengths that are less or equal than $2^{j_k-3}$. Here, we make the standard convention that $[a, a] = \{a\}$ for $a \in \mathbb{R}$. For such a choice of $a_k^{(1)}, \ldots, a_k^{(8)}$, we define

$$\Lambda'_k := \{a_k^{(1)}, \ldots, a_k^{(8)}\}.$$  

If we set $\tilde{\Lambda} := \Lambda \cup \Lambda' \cup (2^{j+3})_{j \in \mathbb{N}_0}$ and regard it as a sequence i.e. $\tilde{\Lambda} = (\tilde{\lambda}_k)_{k \in \mathbb{N}_0}$, then $\tilde{\lambda}_0 = \lambda_0^{(d)} = 8$ and for every $k \in \mathbb{N}$ there exists a $k' \in \mathbb{N}$ such that $[\tilde{\lambda}_{k'-1}, \tilde{\lambda}_k] \subseteq [\lambda_k^{(d)} - 1, \lambda_k^{(d)}] \subseteq [2^{j_k'-1}, 2^{j_k'})$. Hence, property (1) is satisfied for $j_k = j_k'$. To verify property (2), observe that by the definition of $\Lambda'$ one has

$$\#(\Lambda' \cap \{2^{N-1}, \ldots, 2^N\}) \leq 8(\#(\Lambda \cap \{2^{N-1}, \ldots, 2^N\}) + 2)$$

and so,

$$\#(\tilde{\Lambda} \cap \{2^{N-1}, \ldots, 2^N\}) \leq \#(\Lambda' \cap \{2^{N-1}, \ldots, 2^N\}) + \#(\Lambda \cap \{2^{N-1}, \ldots, 2^N\}) + 2 \leq 9(\#(\Lambda \cap \{2^{N-1}, \ldots, 2^N\}) + 2).$$

Hence, the proof of the lemma is complete. $\square$

Note that if $\tilde{\Lambda}$ is as in Lemma 6, then one has

$$S^{(\tilde{\Lambda})}(f)(x) \lesssim S^{(\tilde{\Lambda})}(f)(x) \quad (x \in \mathbb{T}) \quad (4.3)$$

for every trigonometric polynomial $f$ on $\mathbb{T}$. Hence, it is enough to work with the operator $S^{(\tilde{\Lambda})}$ instead of $S^{(\Lambda)}$ in view of (4.3).

We now fix a function $f \in L \log^{1/2} L(\mathbb{T})$. For every given $k \in \mathbb{N}$, we consider $j_k \in \mathbb{N}$ as in Lemma 6, namely $j_k$ is the positive integer satisfying the property $[\lambda_{k-1}, \lambda_k) \subseteq [2^{j_k-1}, 2^{j_k})$ and we then set

$$\tilde{F}_k := F_{j_k}, \quad (4.4)$$
where \((F_j)_{j \in \mathbb{N}}\) is the sequence of non-negative functions associated to \(f\) such that (4.1) and (4.2) hold. Then, an adaptation of the proof of [43, Proposition 5.1] to the periodic setting, where one uses (4.1) and (4.2) instead of [43, Proposition 4.1], yields that

\[
\| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\widetilde{\Lambda})}(f) \|_{L^{1,\infty}(\mathbb{T})} \lesssim \left\| \left( \sum_{k \in \mathbb{N}} |\widetilde{F}_k|^2 \right)^{1/2} \right\|_{L^1(\mathbb{T})}
\]

where the implied constant does not depend on \(\Lambda, \omega,\) and \(N \in \mathbb{N}\). As it is of crucial importance for the proof here that the implied constant in (4.5) is independent of \(\Lambda, \omega, \) and \(N \in \mathbb{N}\), and, moreover, as some of the technicalities in the periodic setting are slightly more involved than the ones in the Euclidean case, for the convenience of the reader, in Sect. 4.1, we present how (4.5) can be obtained by adapting the arguments of Tao and Wright [43] to our case.

Assuming now that (4.5) holds, note that it easily follows from the definition (4.4) of \((\widetilde{F}_k)_{k \in \mathbb{N}_0}\) and the second property of \(\widetilde{\Lambda}\) in Lemma 6 that there exists an absolute constant \(A > 0\) such that

\[
\left( \sum_{k \in \mathbb{N}} |\widetilde{F}_k(x)|^2 \right)^{1/2} \leq A(\rho_\Lambda - 1)^{-1/2} \left( \sum_{j \in \mathbb{N}} |F_j(x)|^2 \right)^{1/2} \quad \text{for a.e. } x \in \mathbb{T}.
\]

Hence, (4.2), (4.5), and (4.6), combined with the fact that \(\Delta_0^{(\widetilde{\Lambda})} = T_{|\lambda_0 - 1, \ldots, \lambda_0 - 1|}\) is of weak-type \((1, 1)\) with corresponding operator norm independent of \(\Lambda\), imply that

\[
\left\| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\widetilde{\Lambda})}(f) \right\|_{L^{1,\infty}(\mathbb{T})} \leq \frac{C_0}{(\rho_\Lambda - 1)^{1/2}} \left[ 1 + \int_{\mathbb{T}} |f(x)| \log^{1/2}(e + |f(x)|) \, dx \right],
\]

where \(C_0 > 0\) is an absolute constant that is independent of \(f, \Lambda, \omega,\) and \(N\).

We shall now argue as in [2]. More precisely, by using (4.7) as well as the trivial estimate

\[
\left\| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\widetilde{\Lambda})} \right\|_{L^2(\mathbb{T}) \to L^2(\mathbb{T})} = 1,
\]

then a Marcinkiewicz-type interpolation argument implies that

\[
\left\| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\widetilde{\Lambda})} \right\|_{L \log^{3/2} L(\mathbb{T}) \to L^1(\mathbb{T})} \leq \frac{A_0}{(\rho_\Lambda - 1)^{1/2}},
\]
where \( A_0 > 0 \) does not depend on \( \Lambda \), and the choice of \( \omega \in \Omega \), \( N \in \mathbb{N} \). More specifically, for a trigonometric polynomial \( g \) on \( \mathbb{T} \), write

\[
\left\| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\lambda)}(g) \right\|_{L^1(\mathbb{T})} \leq (2\pi)^{-1} (I_1 + I_2),
\]

where

\[
I_1 := \int_{0}^{\infty} \left\{ x \in \mathbb{T} : \left| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\lambda)}(g \chi_{\{|g|>\alpha\}})(x) \right| > \alpha/2 \right\} d\alpha
\]

and

\[
I_2 := \int_{0}^{\infty} \left\{ x \in \mathbb{T} : \left| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\lambda)}(g \chi_{\{|g|\leq\alpha\}})(x) \right| > \alpha/2 \right\} d\alpha.
\]

To bound \( I_1 \), we only use (4.7) and Fubini’s theorem,

\[
I_1 \leq 2\pi + \frac{4C_0}{(\rho_\lambda - 1)^{1/2}} \int_{1}^{\infty} \frac{1}{\alpha} \left[ \int_{\{|g|>\alpha\}} \frac{1}{\alpha} \int_{\{|g|>\alpha\}} |g(x)| \log^{1/2}(e + |g(x)|) dx \right] d\alpha
\]

\[
\leq \frac{2\pi + 4C_0}{(\rho_\lambda - 1)^{1/2}} \left[ 1 + \int_{\mathbb{T}} |g(x)| \log^{3/2}(e + |g(x)|) dx \right],
\]

whereas for \( I_2 \), we use (4.8) and Fubini’s theorem,

\[
I_2 \leq 4 \int_{1}^{\infty} \frac{1}{\alpha^2} \left[ \int_{\{|g|\leq\alpha\}} |g(x)|^2 dx \right] d\alpha \leq 4 \int_{\mathbb{T}} |g(x)|^2 \left[ \int_{\{|g|\leq\alpha\}} \frac{1}{\alpha^2} dx \right] d\alpha
\]

\[
\leq 4 \int_{\mathbb{T}} |g(x)| dx
\]

\[
\leq 4 \int_{\mathbb{T}} |g(x)| \log^{3/2}(e + |g(x)|) dx.
\]

By using a simple density argument, we conclude that (4.9) holds for \( A_0 := 2\pi + 4C_0 + 4 \) with \( C_0 \) being as in (4.7). See also, e.g. [2, Lemma 3.2] for a more general Marcinkiewicz-type interpolation result between Orlicz spaces.

Therefore, arguing again as in [2], it follows from (4.8), (4.9), and Tao’s converse extrapolation theorem [42] that

\[
\left\| \sum_{k=0}^{N} r_k(\omega) \Delta_k^{(\lambda)} \right\|_{L^p(\mathbb{T}) \rightarrow L^p(\mathbb{T})} \lesssim \frac{1}{(p-1)^{3/2}} (\rho_\lambda - 1)^{-1/2} \quad (1 < p < 2),
\]

where the implied constant does not depend on \( \Lambda \) and \( \omega, N \).
To justify the last step, notice that if $T$ is a linear, translation-invariant operator acting on functions defined over the torus and such that $\|T\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \leq 1$ for some $p_0 > 1$ and $\|T\|_{L^\infty(\mathbb{T}) \to L^1(\mathbb{T})} \leq D_0$ for some $r > 0$, then by carefully examining the proof of [42, Theorem 1.1], one deduces that

$$\|T\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \leq D_0 M_{r,p_0}(p - 1)^{-r} \quad (p \to 1^+),$$

(4.11)

where $M_{r,p_0} > 0$ is a constant depending only on $r$ and $p_0$, but not on $D_0$. Indeed, if $T$ is above, then note that in the proof of [42, Theorem 1.1], $\|T\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})}$ is estimated by the sum of the quantities on the right-hand sides of [42, (13)] and [42, (14)]. In the proof of [42, (13)] only the fact that $T$ is bounded on $L^{p_0}(\mathbb{T})$ is used in [42]. Moreover, it follows from the argument in [42, Section 3] that the implicit constant on the right-hand side of [42, (14)] depends linearly on the implicit constant in [42, (1)]. In turn, the proof of [42, Lemma 2.1] yields that the implicit constant of (4.11) holds. To complete the justification of (4.10), observe that in our case we have $T = \sum_{k=0}^{N} r_k(\omega) \Delta_k(\lambda)$ and so, by employing (4.8) (i.e. $p_0 = 2$) and (4.9), we may take $r = 3/2$ and $D_0 = A_0(\rho_\Lambda - 1)^{-1/2}$. We thus see that (4.10) indeed holds, in view of (4.11).

Therefore, the proof of (1.5) is now obtained by using (4.10), Khintchine’s inequality (2.5), and (4.3).

**Remark 7** By using a modification of the argument presented in Subsection 3.1, one can show that the exponent $r = 1/2$ in $(\rho_\Lambda - 1)^{-1/2}$ in (1.5) is best possible asymptotically in the sense that for every $\lambda$ ‘close’ to $1^+$ there exists a lacunary sequence $\Lambda$ with ratio $\rho_\Lambda \in [\lambda, \lambda^2)$ such that

$$(\rho_\Lambda - 1)^{-1/2} \leq \liminf_{p \to 1^+} \left[ (p - 1)^{3/2} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \right].$$

Furthermore, as in Sect. 3.1.1, it would seem natural to expect that one actually has

$$\|S^{(\Lambda)}\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \lesssim \frac{1}{(p - 1)^{3/2}} (\rho_\Lambda - 1)^{-1/2 + (p - 1)/p}$$

for all $p \in (1, 2]$ and for every lacunary sequence $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ in $\mathbb{N}$ with ratio $\rho_\Lambda \in (1, 2]$.

**Remark 8** Notice that, given a rational number $\lambda$ ‘close’ to $1^+$, if $\Lambda_0$ is as in Sect. 3.1.1, then $\rho_{\Lambda_0} = \lambda$ but one can show that

$$\|S^{(\Lambda_0)}\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \sim (p - 1)^{-3/2} \quad (1 < p \leq 2),$$

(4.12)

namely $\|S^{(\Lambda_0)}\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})}$ can be taken to be independent of $\lambda$.

Similarly, one can show that (4.12) holds for every lacunary sequence $\Lambda = (\lambda_j)_{j \in \mathbb{N}_0}$ with ratio $\rho_\Lambda \geq 2$. 

\[ \text{ Springer} \]
Remark 9 The argument presented in this section can also be used to give an alternative proof of Theorem 1. More specifically, one can prove (1.6) for $X = H^1(\mathbb{T})$ by adapting the proof of Tao and Wright that establishes [43, Proposition 5.1] to the periodic setting, where instead of [43, Proposition 9.1] one uses directly a standard Littlewood–Paley estimate for functions in $H^1(\mathbb{T})$. More precisely, given an $f \in H^1(\mathbb{T})$, if one defines $F_j := |\tilde{\Delta}_j(f)|$ then it follows from the work of Tao and Wright adapted to the torus (see also the next subsection) that for every choice of $\omega \in \Omega$ and $N \in \mathbb{N}$ one has

$$
\left\| \sum_{k=0}^{N} r_k(\omega) \Delta_k(f) \right\|_{L^1(\mathbb{T}; L^1(\mathbb{T}))} \lesssim (\rho - 1)^{-1/2} \left( \sum_{j \in \mathbb{N}_0} |\tilde{\Delta}_j(f)|^2 \right)^{1/2},
$$

(4.13)

Hence, by using the following Littlewood–Paley inequality

$$
\left\| \left( \sum_{j \in \mathbb{N}_0} |\tilde{\Delta}_j(f)|^2 \right)^{1/2} \right\|_{L^1(\mathbb{T})} \lesssim \|f\|_{H^1(\mathbb{T})},
$$

(4.14)

together with (4.13), (2.5), and (4.3), one obtains (1.6) for $X = H^1(\mathbb{T})$. Note that (4.14) is a consequence of e.g. [16, Theorem 1.20] or the work of Stein [38,39].

4.1 Proof of (4.5)

In this subsection, we show how one can adapt the argument on pp. 535–540 in [43] to the periodic setting and establish (4.5).

To this end, fix a function $f \in L \log^{1/2} L(\mathbb{T})$ and let $F_k := (F_k)_{k \in \mathbb{N}}$ be as above. We shall prove that for every $\alpha > 0$ one has

$$
\left\| \sum_{k=1}^{N} r_k(\omega) \Delta_k(f)(x) \right\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))} \leq \frac{C_0}{\alpha} \|F\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))},
$$

(4.15)

where $C_0 > 0$ is an absolute constant, independent of $\omega$, $\Lambda$, $\alpha$, $f$, and $N \in \mathbb{N}$. Towards this aim, fix an $\alpha > 0$ and consider the set

$$
\Omega_\alpha := \left\{ x \in \mathbb{T} : \sum_{k=1}^{N} r_k(\omega) \Delta_k(f)(x) > \alpha \right\},
$$

where $M_c$ denotes the centred Hardy–Littlewood maximal function acting on functions defined over $\mathbb{T}$. Then one has

$$
|\Omega_\alpha| \leq \frac{N_0}{\alpha} \|\tilde{F}\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))},
$$

(4.16)

where $N_0 := \|M_c\|_{L^1(\mathbb{T})} \to L^1(\mathbb{T}) < \infty$. By using a Whitney-type covering lemma; see e.g. pp. 167–168 in [40], it follows that there exists a countable collection of arcs...
(J) \in \mathcal{J} \text{ in } \mathbb{T} \text{ whose interiors are mutually disjoint, satisfy } |J| \leq 1/8 \text{ for all } J \in \mathcal{J} \text{ as well as the properties}

$$\Omega_\alpha = \bigcup_{J \in \mathcal{J}} J$$  \quad (4.17)

and

$$c_0^{-1} |J| \leq \text{dist}(\mathbb{T} \setminus \Omega_\alpha, J) \leq c_0 |J| \text{ for all } J \in \mathcal{J} \quad (4.18)$$

where \(c_0 > 0\) is an absolute constant. We thus have

$$\sum_{J \in \mathcal{J}} |J| \leq \frac{N_0}{\alpha} \| \tilde{F} \|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}, \quad (4.19)$$

where the absolute constant \(N_0 > 0\) is as in (4.16). Moreover, it follows from the definition of \(\Omega_\alpha\) that

$$\| \tilde{F}(x) \|_{\ell^2(\mathbb{N})} \leq \alpha \text{ for a.e. } x \in \mathbb{T} \setminus \Omega_\alpha. \quad (4.20)$$

Furthermore, (4.17) and (4.18) imply that

$$\frac{1}{|J|} \int_J \| \tilde{F}(x) \|_{\ell^2(\mathbb{N})} \, dx \lesssim \alpha \text{ for all } J \in \mathcal{J} \quad (4.21)$$

where the implied constant in (4.21) is independent of \(F\) and \(\alpha\). Define \(G = (g_k)_{k \in \mathbb{N}}\) by

$$g_k(x) := \begin{cases} |J|^{-1} \int_J \tilde{F}_k(y) \, dy, & \text{if } x \in J \\ \tilde{F}_k(x), & \text{if } x \in \mathbb{T} \setminus \Omega_\alpha. \end{cases}$$

Using (4.20), (4.21) as well as Minkowski’s integral inequality one deduces that

$$\| G \|_{L^2(\mathbb{T}; \ell^2(\mathbb{N}))} \lesssim \alpha \| \tilde{F} \|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}, \quad (4.22)$$

where the implied constant in (4.22) does not depend on \(F\) and \(\alpha\). We also define \(B = (b_k)_{k \in \mathbb{N}}\) by

$$b_k := \tilde{F}_k - g_k, \quad k \in \mathbb{N}.$$  

Then it easily follows from (4.21) that

$$\int_J \| B(x) \|_{\ell^2(\mathbb{N})} \, dx \lesssim \alpha |J| \text{ for all } J \in \mathcal{J}, \quad (4.23)$$
where the implied constant in \((4.23)\) is independent of \(F\) and \(\alpha\). Notice that we also have that \(\int_J b_k(x)dx = 0\) for all \(k \in \mathbb{N}\), but we will not exploit this property here.

Next, we write \(\widetilde{\lambda} = (\widetilde{\lambda}_k)_{k \in \mathbb{N}_0}\) and for \(k \in \mathbb{N}\) define the intervals

\[ I_k := [\widetilde{\lambda}_{k-1}, \widetilde{\lambda}_k) \quad \text{and} \quad I'_k := (-\widetilde{\lambda}_k, -\widetilde{\lambda}_{k-1}]. \]

Observe that

\[ \Delta_k(\widetilde{\lambda}) = \Delta_k(\widetilde{\lambda}^+, \widetilde{\lambda}^-), \]

where \(\Delta_k(\widetilde{\lambda}^+, \widetilde{\lambda}^-) := T_{\chi_k|\mathbb{Z}}\) and \(\Delta_k(\widetilde{\lambda}^-, \widetilde{\lambda}^+) := T_{\chi'_k|\mathbb{Z}}\). Hence, to prove \((4.15)\), it suffices to show that

\[
\left\{ x \in \mathbb{T} : \left| \sum_{k=1}^N r_k(\omega) \Delta_k(\widetilde{\lambda}^+, \widetilde{\lambda}^-)(f)(x) \right| > \alpha/2 \right\} \leq C_0 \frac{2}{\alpha} \left\| \tilde{F} \right\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))} \tag{4.24} \]

and

\[
\left\{ x \in \mathbb{T} : \left| \sum_{k=1}^N r_k(\omega) \Delta_k(\widetilde{\lambda}^-, \widetilde{\lambda}^+)(f)(x) \right| > \alpha/2 \right\} \leq C_0 \frac{2}{\alpha} \left\| \tilde{F} \right\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}, \tag{4.25} \]

where \(C_0\) is the constant in \((4.15)\).

We shall only focus on the proof of \((4.24)\), as the proof of \((4.25)\) is completely analogous. To prove \((4.24)\), for \(k \in \mathbb{N}\), consider the function

\[ \phi_{I_k}(x) := \left| I_k \right| \left[ 1 + \left| I_k \right|^2 \sin^2(x/2) \right]^{-3/4}, \quad x \in \mathbb{T} \]

and for a fixed function \(\psi \in S(\mathbb{R})\) that is even, supported in \([-2, 2]\) and such that \(\psi|_{[-1, 1]} \equiv 1\), define \(\psi_k\) by

\[ \psi_k(\xi) := \psi\left( \left| I_k \right|^{-1} \left| \xi - \xi_{I_k} \right| \right), \quad \xi \in \mathbb{R}, \]

where \(\xi_{I_k}\) denotes the centre of \(I_k\). Consider now the multiplier \(T_{\psi_k|\mathbb{Z}}\) and note that it follows from the definition of \(\psi_k\) and Lemma 6 that

\[ T_{\psi_k|\mathbb{Z}}(f) = T_{\psi_k|\mathbb{Z}}(\widetilde{\lambda}_{j_k})(f),\]

where \(j_k \in \mathbb{N}\) is such that \(I_k \subseteq [2^{j_k-1}, 2^{j_k})\) and \(\widetilde{\lambda}_{j_k} = T_{\eta_{j_k}|\mathbb{Z}}\) with \(\eta_j\) being as in the previous section. Hence, it follows from \((4.1)\) and the smoothness of \(\psi\) that there exists an absolute constant \(M_0 > 0\) such that

\[
|T_{\psi_k|\mathbb{Z}}(f)(x)| \leq M_0 (\tilde{F}_k * \phi_{I_k} * \phi_{j_k})(x) \quad \text{for all} \ x \in \mathbb{T}, \tag{4.26} \]

\(\triangledown\) Springer
where \( j_k \in \mathbb{N} \) is as above, i.e. \( I_k \subseteq [2^{j_k-1}, 2^{j_k}) \) and \( \phi_{j_k} \) is as in the previous section, namely \( \phi_{j_k}(x) = 2^{j_k}[1 + 2^{j_k} \sin^2(x/2)]^{-3/4}, x \in \mathbb{T} \). For \( k \in \{1, \ldots, N\} \), if \( \widetilde{F}_k \) is not identically zero, define the function \( a_k \) by

\[
 a_k(x) := T_{\psi_k|_L}(f)(x) \left[ (\widetilde{F}_k \ast \phi_{I_k} \ast \phi_{j_k})(x) \right]^{-1}, \quad x \in \mathbb{T}.
\]

Otherwise, define \( a_k(x) := 0, x \in \mathbb{T} \). Hence, the definition of \( a_k \) and (4.26) imply that \( \|a_k\|_{L^{\infty}(\mathbb{T})} \leq M_0 \) for all \( k \in \mathbb{N} \). For each \( k \in \mathbb{N} \), we thus have that

\[
 \Delta_k^{(\widetilde{A}, +)}(f) = \Delta_k^{(\widetilde{A}, +)}(T_{\psi_k|_L}(f)) = \Delta_k^{(\widetilde{A}, +)}(a_k(\widetilde{F}_k \ast \phi_{I_k} \ast \phi_{j_k}))
\]

and so, to prove (4.24), it suffices to show that

\[
 \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\widetilde{A}, +)}(a_k(\widetilde{F}_k \ast \phi_{I_k} \ast \phi_{j_k}))(x) \right| > \frac{\alpha}{2} \right\} \leq \frac{C_0'}{\alpha} \left\| \widetilde{F} \right\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))},
\]

where \( C_0' > 0 \) is an absolute constant that does not depend on \( \omega, \Lambda, \alpha, f, \) and \( N \). Since \( \widetilde{F}_k = g_k + b_k \), it is enough to prove that

\[
 \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\widetilde{A}, +)}(a_k(g_k \ast \phi_{I_k} \ast \phi_{j_k}))(x) \right| > \frac{\alpha}{4} \right\} \leq \frac{C_0''}{\alpha} \left\| \widetilde{F} \right\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}
\]

and

\[
 \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\widetilde{A}, +)}(a_k(b_k \ast \phi_{I_k} \ast \phi_{j_k}))(x) \right| > \frac{\alpha}{4} \right\} \leq \frac{C_0''}{\alpha} \left\| \widetilde{F} \right\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}
\]

for some absolute constant \( C_0'' > 0 \).

To establish the first bound involving \( G = (g_k)_{k \in \mathbb{N}} \), note that by using Chebyshev’s inequality, Parseval’s identity twice as well as the fact that \( \|a_k\|_{L^{\infty}(\mathbb{T})} \leq M_0 \) for all \( k \in \mathbb{N} \), one obtains

\[
 \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\widetilde{A}, +)}(a_k(g_k \ast \phi_{I_k} \ast \phi_{j_k}))(x) \right| > \frac{\alpha}{4} \right\} \lesssim \frac{1}{\alpha^2} \sum_{k=1}^{N} \left\| g_k \ast \phi_{I_k} \ast \phi_{j_k} \right\|_{L^2(\mathbb{T})}^2,
\]

where the implied constant is independent of \( \omega, \Lambda, \alpha, f, \) and \( N \). Using now Young’s inequality twice combined with the fact that there exists an absolute constant \( C > 0 \)
such that \( \| \phi_I_k \|_{L^1(T)} \leq C \) and \( \| \phi_{jk} \|_{L^1(T)} \leq C \) for all \( k \in \mathbb{N} \), we deduce that 

\[
\left\{ x \in T : \left| \sum_{k=1}^N r_k(\omega) \Delta_k^{(k,+,)} (a_k (g_k * \phi_I_k * \phi_{jk})) (x) \right| > \frac{\alpha}{4} \right\} \lesssim \frac{1}{\alpha^2} \| G \|_{L^2(T; \ell^2(\mathbb{N}))}^2,
\]

where the implied constant does not depend on \( \omega, \Lambda, \alpha, f \), and \( N \). Hence, the desired inequality for \( G = (g_k)_{k \in \mathbb{N}} \) follows from the last estimate combined with (4.22).

To prove the desired weak-type inequality involving \( B = (b_k)_{k \in \mathbb{N}} \), for \( J \in \mathcal{J} \) we write

\[ b_{k,J} := \chi_J b_k, \quad k \in \mathbb{N} \]

and, as in [43], we have

\[
\left\{ x \in T : \left| \sum_{k=1}^N r_k(\omega) \Delta_k^{(k,+,)} (a_k (b_k * \phi_I_k * \phi_{jk})) (x) \right| > \frac{\alpha}{4} \right\} \leq I_1 + I_2,
\]

where

\[
I_1 := \left\{ x \in T : \left| \sum_{k=1}^N r_k(\omega) \Delta_k^{(k,+,)} \left( a_k \left[ \left( \sum_{J \in \mathcal{J} : |I_k|/|J| \leq 1} b_{k,J} * \phi_I_k * \phi_{jk} \right) \right] \right) (x) \right| > \frac{\alpha}{8} \right\}
\]

and

\[
I_2 := \left\{ x \in T : \left| \sum_{k=1}^N r_k(\omega) \Delta_k^{(k,+,)} \left( a_k \left[ \left( \sum_{J \in \mathcal{J} : |I_k|/|J| > 1} b_{k,J} * \phi_I_k * \phi_{jk} \right) \right] \right) (x) \right| > \frac{\alpha}{8} \right\}.
\]

We shall prove separately that

\[
I_1 \lesssim \frac{1}{\alpha} \| \widehat{F} \|_{L^1(T; \ell^2(\mathbb{N}))} (4.27)
\]

and

\[
I_2 \lesssim \frac{1}{\alpha} \| \widehat{F} \|_{L^1(T; \ell^2(\mathbb{N}))} (4.28)
\]

where the implied constants in (4.27) and (4.28) do not depend on \( \omega, \Lambda, \alpha, f \), and \( N \).
4.1.1 Proof of (4.27)

To prove the desired bound for $I_1$, observe that by using Chebyshev’s inequality, Parseval’s identity twice, the bound $\|a_k\|_{L^\infty(\mathbb{T})} \leq M_0$ and then Young’s inequality together with the fact that there exists an absolute constant $C > 0$ such that $\|\phi_{jk}\|_{L^1(\mathbb{T})} \leq C$, one has

$$I_1 \lesssim \frac{1}{\alpha^2} \sum_{k=1}^N \left\| \sum_{J: |J_k| \leq 1} |b_{k,J}| \star \phi_{I_k} \right\|^2_{L^2(\mathbb{T})},$$

(4.29)

where the implied constant is independent of $\omega$, $\Lambda$, $\alpha$, $f$, and $N$. To get an appropriate bound for the right-hand side of (4.29), we shall use the following lemma.

**Lemma 10** Let $b_{k,J}$ and $\phi_{I_k}$ be as above.

If $|I_k||J| \leq 1$, then there exists an absolute constant $A_0 > 0$ such that

$$|b_{k,J}| \star \phi_{I_k}(x) \leq A_0 \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}(\chi_J \star \phi_{I_k})(x)$$

(4.30)

for $x \in \mathbb{T}$.

**Proof** We may suppose, without loss of generality, that $2J$ can be regarded as an interval in $[-\pi, \pi)$. To prove (4.30), take an $x \in [-\pi, \pi)$ and consider two cases; $x \not\in 2J$ and $x \in 2J$.

Assume first that $x \not\in 2J$. In the subcase where $|x - y| \leq 3\pi/2$ for all $y \in J$ (with $-\pi \leq y < \pi$) note that for all $y, y' \in J$ we have $|x - y| \geq |x - y'|/3$. Hence, if $y_J$ denotes the centre of $J$, we get

$$|b_{k,J}| \star \phi_{I_k}(x) \lesssim \int_J |b_{k,J}(y)||I_k|(1 + |I_k|^2|x - y|^2)^{-3/4} \, dy$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}|I_k|(1 + |I_k|^2|x - y_J|^2)^{-3/4}$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1} \int_J |I_k|(1 + |I_k|^2|x - y|^2)^{-3/4} \, dy$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}(\chi_J \star \phi_{I_k})(x),$$

where the implied constants in the above chain of inequalities do not depend on $k, J$ and we used the fact that

$$|I_k|(1 + |I_k|^2|x|^2)^{-3/4} \leq \phi_{I_k}(x) \leq 64|I_k|(1 + |I_k|^2|x|^2)^{-3/4}$$

(4.31)

for all $x \in [-3\pi/2, 3\pi/2]$, which is a direct consequence of the elementary inequalities $y/8 \leq \sin(y/2)$ for $y \in [0, 3\pi/2]$ and $\sin(y) \leq y$ for all $y \geq 0$. Notice that the inequality on the left-hand side of (4.31) holds for all $x \in \mathbb{R}$. If we now consider the subcase where $|x - y| > 3\pi/2$ for some $y \in J$ (with $-\pi \leq y < \pi$), then...
\[ |x - y| \sim |x| \sim |y| \] for all \( y \in J \) (noting that \( |J| \leq 1/8 \)) and so, by using (4.31), one has
\[
|b_{k,J} \ast \phi_I_k(x)| \lesssim \int_{[-\pi, \pi]} |b_{k,J}(x-y)||I_k|(1 + |I_k|^2|y|^2)^{-3/4} \, dy
\]
\[
\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}|I_k|(1 + |I_k|^2x^2)^{-3/4}
\]
\[
\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}(\chi_J \ast \phi_I_k)(x).
\]

If \( x \in 2J \), observe that \( |I_k||x - y| \leq 2|I_k||J| \leq 2 \) for all \( y \in J \) and hence, by using the trivial estimate \( |b_{k,J} \ast \phi_I_k(x)| \leq \|b_{k,J}\|_{L^1(\mathbb{T})}|I_k| \) and (4.31), we get
\[
|b_{k,J} \ast \phi_I_k(x)| \leq \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}(\chi_J \ast \phi_I_k)(x),
\]
where the implied constant is independent of \( k, J \). \( \square \)

Using (4.30), (4.29) becomes
\[
I_1 \leq \frac{A'_0}{\alpha^2} \sum_{k=1}^N \left( \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}(\chi_J \ast \phi_I_k)(x) \right)^2,
\]
where \( A'_0 > 0 \) is an absolute constant. Hence, by using (4.32), Fubini’s theorem, and Young’s inequality combined with the fact that \( \|\phi_I_k\|_{L^1(\mathbb{T})} \leq C \), we get
\[
I_1 \leq \frac{A''_0}{\alpha^2} \sum_{k=1}^N \int_{\mathbb{T}} \left( \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}\chi_J(x) \right)^2 \, dx,
\]
where \( A''_0 > 0 \) is an absolute constant. Since the arcs \( (J)_{J \in \mathcal{J}} \) have mutually disjoint interiors, we have
\[
I_1 \leq \frac{B_0}{\alpha^2} \sum_{J \in \mathcal{J}} |J|^{-1} \sum_{k=1}^N \|b_{k,J}\|_{L^1(\mathbb{T})}^2,
\]
where \( B_0 > 0 \) is an absolute constant. Observe that by using Minkowski’s integral inequality and (4.23) one has
\[
\sum_{k=1}^N \|b_{k,J}\|_{L^1(\mathbb{T})}^2 \leq B'_0\alpha^2|J|^2
\]
where \( B'_0 > 0 \) is an absolute constant. Therefore, by using (4.33) together with (4.34) and (4.19), (4.27) follows.
4.1.2 Proof of (4.28)

We shall now estimate the remaining term $I_2$. As in [43], for $k \in \{1, \ldots, N\}$ and $J \in \mathcal{J}$ with $|I_k||J| > 1$, we write

$$b_k, J \ast \phi_{I_k} \ast \phi_{J_k} = \chi_{T \setminus (2J)}(x) (b_k, J \ast \phi_{I_k} \ast \phi_{J_k}) (x) + \chi_{2J}(x) (b_k, J \ast \phi_{I_k} \ast \phi_{J_k}) (x)$$

for $x \in \mathbb{T}$ and hence, we have the inequality

$$I_2 \leq I_2^{(i)} + I_2^{(ii)},$$

(4.35)

where

$$I_2^{(i)} := \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r(k)(\omega) \Delta_k^{(I_k)} \left( \sum_{J \in \mathcal{J}, |I_k||J| > 1} \chi_{T \setminus (2J)}(b_k, J \ast \phi_{I_k} \ast \phi_{J_k}) (x) \right) \right| > \frac{\alpha}{16} \right\}$$

and

$$I_2^{(ii)} := \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r(k)(\omega) \Delta_k^{(I_k)} \left( \sum_{J \in \mathcal{J}, |I_k||J| > 1} \chi_{2J}(b_k, J \ast \phi_{I_k} \ast \phi_{J_k}) (x) \right) \right| > \frac{\alpha}{16} \right\}.$$

We shall first handle the term $I_2^{(i)}$. Towards this aim, we need the following lemma.

**Lemma 11** Assume that $|I_k||J| > 1$.

There exists an absolute constant $C_0 > 0$ such that

$$\left| \chi_{T \setminus (2J)}(x) (|b_k, J| \ast \phi_{I_k} \ast \phi_{J_k}) (x) \right| \leq C_0 \|b_k, J\|_{L^1(T)} |J|^{-1} \left[ M_c(\chi_J)(x) \right]^{3/2}$$

for $x \in \mathbb{T}$.

**Proof** To prove the desired estimate, note that there exists an absolute constant $C > 0$ such that

$$\phi_{I_k} \ast \phi_{J_k}(x) \leq C \left[ \phi_{I_k}(x) + \phi_{J_k}(x) \right]$$

(4.36)

for all $x \in [-\pi, \pi)$. To see this, consider first the case where $x \in [-\pi/2, \pi/2]$ and write

$$\phi_{I_k} \ast \phi_{J_k}(x) = I_1(x) + I_2(x) + I_3(x),$$

where

$$I_1(x) := (2\pi)^{-1} \int_{-\pi \leq y < \pi: |x| > 2|y|} \phi_{J_k}(y) \phi_{I_k}(x - y) dy,$$
\[ I_2(x) := (2\pi)^{-1} \int_{-\pi \leq y < \pi: \frac{2|x|}{|x|}} \phi_{jk}(y)\phi_{Ik}(x-y)dy, \]

and

\[ I_3(x) := (2\pi)^{-1} \int_{-\pi \leq y < \pi: |x/2| \leq |y| \leq 2|x|} \phi_{jk}(y)\phi_{Ik}(x-y)dy. \]

Observe that in this subcase one has \(|x-y| \leq 3\pi/2\) for all \(y \in [-\pi, \pi]\) and so, by using (4.31) twice, one gets

\[
I_1(x) \lesssim \int_{-\pi \leq y < \pi: |x| > 2|y|} |\phi_{jk}(y)||I_k|(1 + |I_k|^2|x-y|^2)^{-3/4} dy \lesssim |I_k|(1 + |I_k|^2|x|^2)^{-3/4} \int_{-\pi \leq y < \pi: |x| > 2|y|} \phi_{jk}(y) dy \lesssim \phi_{Ik}(x) \int_{\mathbb{T}} \phi_{jk}(y) dy.
\]

Since \(\int_{\mathbb{T}} \phi_{jk}(y) dy \lesssim 1\), one deduces that \(I_1(x) = O(\phi_{Ik}(x))\). Similarly, one shows that \(I_2(x) = O(\phi_{Ik}(x))\) and \(I_3(x) = O(\phi_{jk}(x))\). Therefore, by putting the above estimates together, it follows that (4.36) holds when \(x \in [-\pi/2, \pi/2]\). If we now assume that \(x \in [-\pi, \pi]\) and \(|x| > \pi/2\), we write

\[
\phi_{Ik} * \phi_{jk}(x) = (2\pi)^{-1} \int_{-\pi \leq y < \pi: |x-y| \leq 3\pi/2} \phi_{jk}(y)\phi_{Ik}(x-y)dy + (2\pi)^{-1} \int_{|x-y| > 3\pi/2} \phi_{jk}(y)\phi_{Ik}(x-y)dy.
\]

The first integral is handled as in the first case. For the second integral, we have \(|y| \sim |x|\) for all \(y \in [-\pi, \pi]\) with \(|x-y| > 3\pi/2\) and so, by using a version of (4.31) for \(\phi_{jk}\) as well as the fact that \(\int_{\mathbb{T}} \phi_{Ik}(y) dy \lesssim 1\), we get

\[
\int_{-\pi \leq y < \pi: |x-y| > 3\pi/2} \phi_{jk}(y)\phi_{Ik}(x-y)dy \lesssim \int_{-\pi \leq y < \pi: |x-y| > 3\pi/2} 2^{jk}(1 + 2^{2jk}|y|^2)^{-3/4}\phi_{Ik}(x-y)dy \lesssim 2^{jk}(1 + 2^{2jk}|x|^2)^{-3/4} \int_{|x-y| > 3\pi/2} \phi_{Ik}(x-y)dy \lesssim \phi_{jk}(x),
\]

as desired.

Therefore, by using (4.36), one has

\[
|b_{k,J} * \phi_{Ik} * \phi_{jk}(x)| \leq C \left[ |b_{k,J} * \phi_{Ik}(x)| + |b_{k,J} * \phi_{jk}(x)| \right] (x \in \mathbb{T}). \tag{4.37}
\]

\(\mathbb{C}\) Springer
We may suppose that $2J$ can be regarded as an interval in $[-\pi, \pi)$. To estimate the first term on the right-hand side of (4.37), take an $x \in [-\pi, \pi) \setminus 2J$ and consider first the case where $|x - y| \leq 3\pi/2$ for all $y \in J$. Note that, by using (4.31), one has

$$|b_{k,J} \ast \phi_k(x)| \lesssim \int_{-\pi}^{\pi} |b_{k,J}(y)||I_k|((1 + |I_k|^2|x - y|^2)^{-3/4} dy$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}\|I_k|^{-1/2}[\text{dist}(x, J)]^{-3/2}$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}\|J|^{-1}[M_c(\chi_J)(x)]^{3/2}$$

where the constants in the above chain of inequalities do not depend of $k, J$ and we used the assumption that $|I_k||J| > 1$ as well as the fact that $M_c(\chi_J)(x) \sim |J|\text{dist}(x, J)^{-1}$ when $x \notin 2J$. In the case where $|x - y| > 3\pi/2$ for some $y \in J$, one has $|x| \sim |y| \sim |x - y| \sim 1$ for all $y \in J$ and hence,

$$|b_{k,J} \ast \phi_k(x)| \lesssim \int_{-\pi}^{\pi} |b_{k,J}(x - y)||I_k|((1 + |I_k|^2|x|^2)^{-3/4} dy$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}\|I_k|^{-1/2}[\text{dist}(x, J)]^{-3/2}$$

$$\lesssim \|b_{k,J}\|_{L^1(\mathbb{T})}\|J|^{-1}[M_c(\chi_J)(x)]^{3/2}.$$ 

Since we have $2^k|J| \geq |I_k||J| > 1$, a similar argument shows that $|b_{k,J} \ast \phi_j(x)$ is $O(\|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)(x)]^{3/2})$ for $x \notin 2J$ and hence, the proof of the lemma is complete.

Having established Lemma 11, observe that it follows from Chebyshev’s inequality and Parseval’s identity that

$$I_2^{(i)} \leq \frac{C}{\alpha^2} \sum_{k=1}^{\mathcal{N}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)]^{3/2} \left\| \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)]^{3/2} \right\|_{L^2(\mathbb{T})}^2,$$

where $C > 0$ is an absolute constant. Since we may write

$$\left\| \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)]^{3/2} \right\|_{L^2(\mathbb{T})}^2 = (2\pi)^{-1} \int_{\mathbb{T}} \left( \sum_{J \in \mathcal{J}} [M_c(\|b_{k,J}\|_{L^1(\mathbb{T})}^{2/3}|J|^{-2/3}\chi_J)(x)]^{3/2} \right)^2 dx,$$

an application of a periodic version of the Fefferman–Stein maximal theorem [20, Theorem 1 (1)] (for $r = 3/2$ and $p = 3$) gives us that

$$\left\| \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)]^{3/2} \right\|_{L^2(\mathbb{T})}^2 \lesssim \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)]^{3/2} \left\| \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}|J|^{-1}[M_c(\chi_J)]^{3/2} \right\|_{L^2(\mathbb{T})}^2,$$
\[
\lesssim \int_{\mathbb{T}} \left( \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})} |J|^{-1} \chi_J(x) \right)^2 \, dx \\
= \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})}^2 |J|^{-1},
\]

where in the last step we used the fact that the arcs \((J)_{J \in \mathcal{J}}\) have mutually disjoint interiors. We thus deduce that there exists an absolute constant \(A_0 > 0\) such that

\[
\sum_{k=1}^N \left\| \sum_{J \in \mathcal{J}} \|b_{k,J}\|_{L^1(\mathbb{T})} |J|^{-1} \left[ M_c(\chi_J) \right]^{3/2} \right\|_{L^2(\mathbb{T})}^2 \leq A_0 \left( \sum_{J \in \mathcal{J}} |J|^{-1} \sum_{k=1}^N \|b_{k,J}\|_{L^1(\mathbb{T})}^2 \right)^{1/2}.
\]

(4.38)

Hence, by using (4.34), (4.38), and (4.19), it follows that

\[
I_2^{(i)} \lesssim \frac{1}{\alpha} \| \tilde{F} \|_{L^1(\mathbb{T}; l^2(\mathbb{N}))},
\]

where the implied constant does not depend on \(\omega, \Lambda, \alpha,\) and \(f\).

We shall now prove that

\[
I_2^{(ii)} \lesssim \frac{1}{\alpha} \| \tilde{F} \|_{L^1(\mathbb{T}; l^2(\mathbb{N}))},
\]

(4.40)

To this end, for \(|I_k||J| > 1\), we decompose the projection \(\Delta_k^{(\tilde{\Lambda},+)}\) as

\[
\Delta_k^{(\tilde{\Lambda},+)} = \Delta_k^{(\tilde{\Lambda},+)} \circ T_{P_{k,J}} + T_{Q_{k,J}} + \Delta_k^{(\tilde{\Lambda},+)} \circ T_{\tilde{P}_{k,J}},
\]

where the operators \(T_{P_{k,J}}, T_{Q_{k,J}}, T_{\tilde{P}_{k,J}}\) are defined as follows. The operators \(T_{P_{k,J}}\) and \(T_{\tilde{P}_{k,J}}\) are of convolution-type and their kernels \(p_{k,J}\) and \(\tilde{p}_{k,J}\) are trigonometric polynomials given by

\[
p_{k,J}(x) := e^{i\tilde{\lambda}_{k-1}x} K_{||J|-1} (x) \quad (x \in \mathbb{T})
\]

and

\[
\tilde{p}_{k,J}(x) := e^{i(\tilde{\lambda}_k-1)x} K_{||J|-1} (x) \quad (x \in \mathbb{T}),
\]

respectively, where \(K_l\) denotes the Fejér kernel of order \(l \in \mathbb{N}\). Observe that \(T_{P_{k,J}}\) and \(T_{\tilde{P}_{k,J}}\) are multiplier operators and their symbols \(P_{k,J}\) and \(\tilde{P}_{k,J}\) are supported in \(\left\{ \tilde{\lambda}_{k-1} - ||J|-1|, \ldots, \tilde{\lambda}_{k-1} + ||J|-1| \right\}\) and \(\left\{ \tilde{\lambda}_k - 1 - ||J|-1|, \ldots, \tilde{\lambda}_k - 1 + ||J|-1| \right\}\), respectively. The symbol of the multiplier operator \(T_{Q_{k,J}}\) is given by

\[
Q_{k,J}(n) := \chi_{I_k}(n) [1 - P_{k,J}(n) - \tilde{P}_{k,J}(n)], \quad n \in \mathbb{Z}.
\]
Hence, if we set

\[ c_{k,J}(x) := a_k(x)\chi_{2J}(x)(b_{k,J} \star \phi_{k,J})(x) \quad (x \in \mathbb{T}), \]

we have

\[ I_2^{(ii)} \leq A_2^{(ii)} + B_2^{(ii)} + \tilde{A}_2^{(ii)}, \quad (4.41) \]

where

\[ A_2^{(ii)} := \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\chi_{2J})} \left( \sum_{J \in J : |I_k||J| > 1} T_{P_{k,J}}(c_{k,J})(x) \right) \right| > \frac{\alpha}{48} \right\}, \]

\[ B_2^{(ii)} := \left\{ x \in \mathbb{T} : \sum_{k=1}^{N} r_k(\omega) \sum_{J \in J : |I_k||J| > 1} T_{Q_{k,J}}(c_{k,J})(x) > \frac{\alpha}{48} \right\}, \]

and

\[ \tilde{A}_2^{(ii)} := \left\{ x \in \mathbb{T} : \left| \sum_{k=1}^{N} r_k(\omega) \Delta_k^{(\chi_{2J})} \left( \sum_{J \in J : |I_k||J| > 1} T_{\tilde{P}_{k,J}}(c_{k,J})(x) \right) \right| > \frac{\alpha}{48} \right\}. \]

To estimate \( A_2^{(ii)} \), note that by using Chebyshev’s inequality and Parseval’s identity twice, as well as the fact that for every given \( n \in \mathbb{Z} \) there are at most 3 non-zero terms \( (T_{P_{k,J}}(c_{k,J}))^{(\chi_{2J})}(n) \) for \( |I_k||J| > 1 \), one gets

\[ A_2^{(ii)} \leq C_0 \frac{\alpha^2}{\sum_{k=1}^{N} \sum_{J \in J : |I_k||J| > 1} T_{P_{k,J}}(c_{k,J})^2_{L^2(\mathbb{T})}} \quad (4.42) \]

for some absolute constant \( C > 0 \). The right-hand side of (4.42) will essentially be estimated as in the previous case. More precisely, we have the following pointwise bound.

**Lemma 12** If \( T_{P_{k,J}} \) and \( c_{k,J} \) are as above, then one has

\[ |T_{P_{k,J}}(c_{k,J})(x)| \leq C_0 \| b_{k,J} \|_{L^1(\mathbb{T})} |J|^{-1} [M_\epsilon(\chi_J)(x)]^2 \quad \text{for} \ x \in \mathbb{T}, \quad (4.43) \]

where \( C_0 > 0 \) is an absolute constant.
Proof First of all, note that since \( c_k, J \) is supported in \( 2J \), it follows from the definition of \( T_{p_k,J} \) that we may write

\[
|T_{p_k,J}(c_k,J)(x)| \leq (2\pi)^{-1} \int_{2J} |c_k,J(y)| K_{\lfloor |J|-1 \rfloor}(x-y) dy. \tag{4.44}
\]

To prove (4.43), we shall consider two cases; \( x \in 2J \) and \( x \notin 2J \).

If \( x \in 2J \) then we use the trivial bound \( \|a_k\|_{L^\infty(\mathbb{T})} \lesssim 1 \) and so, (4.44) gives

\[
|T_{p_k,J}(c_k,J)(x)| \lesssim |J|^{-1} \|c_k,J\|_{L^1(\mathbb{T})}. \tag{4.45}
\]

Hence, by first using the bound \( \|a_k\|_{L^\infty(\mathbb{T})} \lesssim 1 \) and then Young’s inequality combined with the facts that \( \|\phi_k\|_{L^1(\mathbb{T})} \lesssim 1 \) and \( \|\phi_{j_k}\|_{L^1(\mathbb{T})} \lesssim 1 \), one gets

\[
|T_{p_k,J}(c_k,J)(x)| \lesssim |J|^{-1} \|b_k,J\|_{L^1(\mathbb{T})}. \tag{4.45}
\]

Since \( M_c(\chi_J)(x) \sim 1 \) when \( x \in 2J \), the desired inequality (4.43) follows from the last estimate.

In the case where \( x \notin 2J \), by using (4.44), the definition of the Fejér kernel, one deduces, by arguing as in the proof of Lemma 11, that

\[
|T_{p_k,J}(c_k,J)(x)| \lesssim \|c_k,J\|_{L^1(\mathbb{T})} \lfloor |J|-1 \rfloor^{-1} \left[ \text{dist}(x, J) \right]^{-2}. \tag{4.45}
\]

Since \( \|c_k,J\|_{L^1(\mathbb{T})} \lesssim \|b_k,J\|_{L^1(\mathbb{T})} \) and \( M_c(\chi_J)(x) \sim |J| \left[ \text{dist}(x, J) \right]^{-1} \) when \( x \notin 2J \), the desired estimate (4.43) follows from (4.45).

By using (4.43), (4.42) gives

\[
A_2^{(ii)} \lesssim \frac{1}{\alpha^2} \sum_{k=1}^{N} \int_{\mathbb{T}} \left( \sum_{J \in \mathcal{J}} \|b_k,J\|_{L^1(\mathbb{T})} \lfloor |J|-1 \rfloor^{-1} \left[ M_c(\chi_J)(x) \right]^2 \right)^2 dx
\]

and so, by arguing as in the previous case, namely by using a periodic version of [20, Theorem 1 (i)] (this time for \( r = 2 \) and \( p = 4 \)) as well as (4.34), we deduce that

\[
A_2^{(ii)} \lesssim \sum_{J \in \mathcal{J}} |J|.
\]

It thus follows from the last estimate combined with (4.19) that

\[
A_2^{(ii)} \lesssim \frac{1}{\alpha} \|\tilde{F}\|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}, \tag{4.46}
\]
where the implied constant does not depend on $\omega$, $\Lambda$, $\alpha$, and $f$. Similarly, one proves that

$$\tilde{A}_2^{(ii)} \lesssim \frac{1}{\alpha} \| \tilde{F} \|_{L^1(\mathbb{T}; l^2(\mathbb{N}))},$$

(4.47)

where the implied constant does not depend on $\omega$, $\Lambda$, $\alpha$, and $f$.

To obtain an appropriate estimate for $B_2^{(ii)}$, observe that by using Chebyshev’s inequality, the triangle inequality as well as by exploiting the translation-invariance of the operator

$$\sum_{k \in \{1, \ldots, N\}; \ |I_k||J| > 1} r_k(\omega)T_{Q_k,J},$$

one gets

$$B_2^{(ii)} \leq 4 \sum_{J \in \mathcal{J}} |J| + \frac{48}{\alpha} \sum_{J \in \mathcal{J}} \left\| \sum_{k \in \{1, \ldots, N\}; \ |I_k||J| > 1} r_k(\omega)T_{Q_k,J}(c_k,J) \right\|_{L^1(\mathbb{T}\setminus2\mathcal{J})},$$

(4.48)

where $\tilde{J}$ denotes the arc $[-|J|, |J|]$ in $\mathbb{T}$ (noting that by our construction $|J| \leq 1/8$) and $\tilde{c}_{k,J}$ is a translated copy of $c_{k,J}$ such that supp$(\tilde{c}_{k,J}) \subseteq \tilde{J}$. We thus see that, in view of (4.19), it suffices to handle the second term on the right-hand side of (4.48).

To this end, fix a Schwartz function $s$ supported in $[-1, 1]$ with $s(0) = 1$ and set $s_J(x) := s(|J|^{-1}x)$. Hence, supp$(s_J) \subseteq \tilde{J} = [-|J|, |J|]$ and $s_J(0) = 1$. So, if $\sigma_J$ denotes the periodisation of $s_J$, then supp$(\sigma_J) \subseteq \tilde{J}$ and moreover, the Fourier coefficients of $\sigma_J$ satisfy the properties

$$\hat{\sigma}_J(n) = |J| \hat{s}(|J|n) \quad \text{for all } n \in \mathbb{Z}$$

(4.49)

and

$$\sum_{n \in \mathbb{Z}} \hat{\sigma}_J(n) = 1.$$  

(4.50)

Consider now the multiplier operator $T_{R_k,J}$ whose symbol $R_{k,J}$ is given by

$$R_{k,J}(n) := Q_{k,J}(n) - (Q_{k,J} * \sigma_J)(n), \quad n \in \mathbb{Z}.$$ 

Notice that if $q_{k,J}$ denotes the kernel of $T_{Q_{k,J}}$, then one has

$$T_{R_{k,J}}(\tilde{c}_{k,J})(x) = (2\pi)^{-1} \int_{\tilde{J}} \tilde{c}_{k,J}(y)q_{k,J}(x - y)[1 - \sigma_J(x - y)]dy$$

$$= (2\pi)^{-1} \int_{\tilde{J}} \tilde{c}_{k,J}(y)q_{k,J}(x - y)dy$$
for all \( x \in \mathbb{T} \setminus (2\tilde{J}) \) and so, it is enough to show that for every \( J \in \mathcal{J} \) one has

\[
\left\| \sum_{k \in \{1, \ldots, N\}: |I_k||J| > 1} r_k(\omega)T_{R_k,J}(\tilde{c}_k,J) \right\|_{L^1(\mathbb{T}\setminus(2\tilde{J}))} \leq D_0|J|\alpha, \tag{4.51}
\]

where \( D_0 > 0 \) is an absolute constant. Towards this aim, consider the trigonometric polynomial

\[
\gamma(x) := e^{ix} - 1 \quad (x \in \mathbb{T})
\]

and observe that, by using the Cauchy–Schwarz inequality, the left-hand side of (4.51) is majorised by

\[
\left\| (\gamma)^{-1} \right\|_{L^2(\mathbb{T}\setminus(2\tilde{J}))} \left\| \gamma \cdot \left( \sum_{k \in \{1, \ldots, N\}: |I_k||J| > 1} r_k(\omega)T_{R_k,J}(\tilde{c}_k,J) \right) \right\|_{L^2(\mathbb{T})} \lesssim |J|^{-1/2}BJ,
\]

where

\[
BJ := \left[ \sum_{n \in \mathbb{Z}} \left( \sum_{k \in \{1, \ldots, N\}: |I_k||J| > 1} \left| R_{k,J}(n+1)(\tilde{c}_k,J)(n+1) - R_{k,J}(n)(\tilde{c}_k,J)(n) \right| \right)^2 \right]^{1/2}.
\]

Hence, by using Parseval’s theorem, one has

\[
\left\| \sum_{k \in \{1, \ldots, N\}: |I_k||J| > 1} r_k(\omega)T_{R_k,J}(\tilde{c}_k,J) \right\|_{L^1(\mathbb{T}\setminus(2\tilde{J}))} \lesssim |J|^{-1/2}BJ, \tag{4.52}
\]

We shall prove that there exists an absolute constant \( C_0 > 0 \) such that

\[
BJ \leq C_0|J|^{3/2}\alpha \tag{4.53}
\]

for every \( J \in \mathcal{J} \). To show (4.53), given a \( k \in \{1, \ldots, N\} \) such that \( |I_k||J| > 1 \), consider the following subsets of \( I_k \),

\[
L_{k,J} := \{\tilde{\lambda}_{k-1}, \ldots, \tilde{\lambda}_{k-1} + \lfloor |J|^{-1} \rfloor \}
\]

and

\[
L'_{k,J} := \{\tilde{\lambda}_{k} - 1 - \lfloor |J|^{-1} \rfloor, \ldots, \tilde{\lambda}_{k} - 1 \}.
\]
The desired estimate (4.53) will easily be obtained by using the following lemma.

**Lemma 13** Let \( k \in \mathbb{N} \) be such that \( k \leq N \) and let \( J \in \mathcal{J} \) be such that \(|I_k| |J| > 1\). If \( L_k, J, L'_k, J \) are as above, then for every \( n \in \mathbb{Z} \) one has

\[
|R_{k,J}(n)| \lesssim \left[ M_d(\chi_{L_k,J})(n) \right]^2 + \left[ M_d(\chi'_{L_k,J})(n) \right]^2
\]

and

\[
|R_{k,J}(n+1) - R_{k,J}(n)| \lesssim |J| \left[ \left[ M_d(\chi_{L_k,J})(n) \right]^2 + \left[ M_d(\chi'_{L_k,J})(n) \right]^2 \right],
\]

where the implied constants do not depend on \( I_k, J \). Here, \( M_d \) denotes the centred discrete maximal operator.

**Proof** We shall establish (4.54) first. To this end, fix an arbitrary \( n \in \mathbb{Z} \) and consider the following cases; \( n \notin I_k \) and \( n \in I_k \).

**Case 1** If \( n \notin I_k \), then either \( n < \tilde{\lambda}_{k-1} \) or \( n \geq \tilde{\lambda}_k \). Assume first that \( n < \tilde{\lambda}_{k-1} \). Since \( Q_{k,J} \) is supported in \( I_k \), one has

\[
R_{k,J}(n) = - \sum_{l \in I_k} Q_{k,J}(l) \tilde{\sigma}_J(n-l).
\]

Moreover, note that since \( s \in S(\mathbb{R}) \), we deduce from (4.49) that there exists an absolute constant \( A_0 > 0 \) such that

\[
|\tilde{\sigma}_J(l)| \leq A_0 \frac{|J|}{(1 + |J|^2 l^2)^2} \quad \text{for every } l \in \mathbb{Z}.
\]

Hence, by using the fact \( \|Q_{k,J}\|_{L^\infty(\mathbb{Z})} = 1 \), it follows from (4.56) that

\[
|R_{k,J}(n)| \leq A_0 \frac{|J|^{-2}}{\left[ \text{dist}(n, L_k, J) \right]^2} \sum_{l \in I_k} \frac{|J|}{1 + |J|^2 (l-n)^2} \leq A'_0 \left[ M_d(\chi_{L_k,J})(n) \right]^2 \sum_{l \geq n} \frac{|J|}{1 + |J|^2 (l-n)^2},
\]

where \( A'_0 > 0 \) is an absolute constant and in the last step we used the fact if \( A \) is an ‘interval’ in \( \mathbb{Z} \) and \( n \notin A \) then one has \( M_d(A)(n) \sim \#(A)(\text{dist}(n, A))^{-1} \). Hence, by using the last estimate, together with the elementary bound

\[
\sum_{l \geq n} \frac{|J|}{1 + |J|^2 (l-n)^2} \leq 1 + \int_n^\infty \frac{|J|}{1 + |J|^2 (x-n)^2} \, dx = 1 + \int_0^\infty \frac{1}{u^2 + 1} \, du = 1 + \frac{\pi}{2},
\]

it follows that \( |R_{k,J}(n)| \) is \( O([M_d(\chi_{L_k,J})(n)]^2) \) and so, (4.54) holds when \( n < \tilde{\lambda}_{k-1} \). If \( n \geq \lambda_k \), then a similar argument shows that \( |R_{k,J}(n)| \) is \( O([M_d(\chi'_{L_k,J})(n)]^2) \) and hence, (4.54) holds when \( n \notin I_k \).
**Case 2** We shall now prove (4.54) in the case where $n \in I_k$. Towards this aim, observe that if $n \in L_k, J \cup L'_k, J$, then

$$|R_{k,J}(n)| \leq 1 + \sum_{m \in \mathbb{N}} |\sigma_{J}(m)| \lesssim 1 \lesssim [M_d(\chi_{L_k,J})(n)]^2 + [M_d(\chi_{L'_k,J})(n)]^2,$$

where we used (4.56) and the fact that if $A$ is an ‘interval’ in $\mathbb{Z}$ and $n \in A$ then one has $M_d(\chi_A)(n) \sim 1$.

If we now assume that $I_k \setminus (L_k, J \cup L'_k, J) \neq \emptyset$ and $n \in I_k \setminus (L_k, J \cup L'_k, J)$, then $Q_{k,J}(n) = 1$ and so, (4.50) gives

$$|R_{k,J}(n)| \leq \sum_{l < \lambda_k - 1} |\hat{\sigma}_{J}(n-l)| + \sum_{l \in L_k, J} |1 - Q_{k,J}(l)||\hat{\sigma}_{J}(n-l)|$$

$$+ \sum_{l \in L'_k, J} |1 - Q_{k,J}(l)||\hat{\sigma}_{J}(n-l)| + \sum_{l \geq \lambda_k} |\hat{\sigma}_{J}(n-l)|.$$

To bound the second term, note that by using (4.56) and the fact that $\|Q_{k,J}\|_{\ell^\infty(\mathbb{Z})} = 1$, one has

$$\sum_{l \in L_k, J} |1 - Q_{k,J}(l)||\hat{\sigma}_{J}(n-l)| \lesssim \sum_{l \in L_k, J} \frac{|J|}{1 + |J|^2(n-l)^2}$$

$$\lesssim \frac{|J|^{-1}}{[\text{dist}(n, L_k, J)]^2} \#(L_k, J)$$

$$\sim \frac{|J|^{-2}}{[\text{dist}(n, L_k, J)]^2}$$

$$\sim [M_d(\chi_{L_k,J})(n)]^2,$$

where the implied constants are independent of $k$ and $J$. The third term is handled similarly and is $O([M_d(\chi_{L'_k,J})(n)]^2)$. For the first term, notice that by using (4.56) one has

$$\sum_{l < \lambda_k - 1} |\hat{\sigma}_{J}(n-l)| \lesssim \sum_{l < \lambda_k - 1} \frac{|J|}{1 + |J|^2(n-l)^2}$$

$$\lesssim \frac{|J|^{-2}}{[\text{dist}(n, L_k, J)]^2} \sum_{m \in \mathbb{Z}} \frac{|J|}{1 + |J|^2m^2}$$

$$\lesssim [M_d(\chi_{L_k,J})(n)]^2.$$

One shows that the fourth term is $O([M_d(\chi_{L'_k,J})(n)]^2)$ in a completely analogous way. Hence, by putting all the estimates together, we deduce that (4.54) also holds in this subcase.
We shall now prove (4.55). Towards this aim, we argue as in the proof of (4.54) and, for a given \( n \in \mathbb{Z} \), consider the cases where \( n \notin I_k \) and \( n \in I_k \).

**Case 1'** If \( n \notin I_k \), then \( Q_{k,j}(n+1) = Q_{k,j}(n) = 0 \) and so, one has

\[
|R_{k,j}(n+1) - R_{k,j}(n)| = \left| \sum_{l \in \tilde{I}_k} Q_{k,j}(l) \left[ \tilde{\sigma}_j(n+1-l) - \tilde{\sigma}_j(n-l) \right] \right| \\
\leq \sum_{l \in \tilde{I}_k} |\tilde{\sigma}_j(n+1-l) - \tilde{\sigma}_j(n-l)|.
\]

Notice that, since for all \( m \in \mathbb{Z} \) one has \( \tilde{\sigma}_j(m) = |J| \tilde{s}(|J|m) \) and \( s \) is a Schwartz function, it follows from the last estimate and the mean value theorem that

\[
|R_{k,j}(n+1) - R_{k,j}(n)| \leq A |J| \sum_{l \in \tilde{I}_k} \frac{|J|}{(1 + |J|^2 (n-l)^2)^2}, \tag{4.57}
\]

where \( A > 0 \) is an absolute constant. Therefore, by arguing as in case 1, if \( n < \tilde{k}_{k-1} \), the quantity on the right-hand side of (4.57) is \( O(|J| [M_d(\chi_{L_{k,j}}(n))]^2) \), whereas if \( n \geq \tilde{k}_k \), the quantity on the right-hand side of (4.57) is \( O(|J| [M_d(\chi_{L'_{k,j}}(n))]^2) \). We thus deduce that (4.55) holds when \( n \notin I_k \).

**Case 2'** If \( n \notin I_k \), then either \( n \in L_{k,j} \cup L'_{k,j} \) or \( n \in \tilde{I}_k \setminus (L_{k,j} \cup L'_{k,j}) \) (assuming that \( I_k \setminus (L_{k,j} \cup L'_{k,j}) \neq \emptyset \)).

If \( n \in L_{k,j} \cup L'_{k,j} \), we have \( [M_d(\chi_{L_{k,j}}(n))]^2 + [M_d(\chi_{L'_{k,j}}(n))]^2 \sim 1 \) and hence,

\[
|Q_{k,j}(n+1) - Q_{k,j}(n)| \lesssim |J| \sim |J| \left( [M_d(\chi_{L_{k,j}}(n))]^2 + [M_d(\chi_{L'_{k,j}}(n))]^2 \right), \tag{4.58}
\]

where the implied constants do not depend on \( k, J \). As in case 1’, by using the definition of \( \sigma_j \) and the mean value theorem, one has

\[
\sum_{l \in \tilde{I}_k} |Q_{k,j}(l)| |\tilde{\sigma}_j(n+1-l) - \tilde{\sigma}_j(n-l)| \leq A |J| \sum_{m \in \mathbb{Z}} \frac{|J|}{(1 + |J|^2 m^2)^2}.
\]

We thus deduce that the right-hand side of the last inequality is \( O(|J|) \), which combined with (4.58), gives (4.55) in the subcase where \( n \in L_{k,j} \cup L'_{k,j} \).

It remains to treat the subcase where \( n \in \tilde{I}_k \setminus (L_{k,j} \cup L'_{k,j}) \). To this end, note that, in view of (4.50), we may write

\[
R_{k,j}(n+1) - R_{k,j}(n) = S_{k,j}(n) + T_{k,j}(n) + U_{k,j}(n),
\]

\( \square \) Springer
where
\[ S_{k,J}(n) := Q_{k,J}(n + 1) \sum_{l < \tilde{\lambda}_{k-1}} \tilde{\sigma}_J(n + 1 - l) - Q_{k,J}(n) \sum_{l < \tilde{\lambda}_{k-1}} \tilde{\sigma}_J(n - l), \]
and
\[ T_{k,J}(n) := Q_{k,J}(n + 1) \sum_{l \geq \tilde{\lambda}_k} \tilde{\sigma}_J(n + 1 - l) - Q_{k,J}(n) \sum_{l \geq \tilde{\lambda}_k} \tilde{\sigma}_J(n - l), \]
and
\[ U_{k,J}(n) := \sum_{l \in I_k} \left\{ [Q_{k,J}(n + 1) - Q_{k,J}(l)]\tilde{\sigma}_J(n + 1 - l) - [Q_{k,J}(n) - Q_{k,J}(l)]\tilde{\sigma}_J(n - l) \right\}. \]
For the first term, we have
\[
|S_{k,J}(n)| \leq |Q_{k,J}(n + 1) - Q_{k,J}(n)| \sum_{l < \tilde{\lambda}_{k-1}} |	ilde{\sigma}_J(n + 1 - l)| + |Q_{k,J}(n)| \sum_{l < \tilde{\lambda}_{k-1}} |	ilde{\sigma}_J(n + 1 - l) - \tilde{\sigma}_J(n - l)|
\]
and, by arguing as above, we see that both terms on the right-hand side of the last estimate are \(O(|J|[M_d(\chi_{L,J})(n)]^2))\). Similarly, one shows that \(|T_{k,J}(n)|\) is \(O(|J|[M_d(\chi_{L'_{k,J}})(n)]^2))\). For the last term, observe that if \(n \in I_k \setminus (L_{k,J} \cup L'_{k,J})\), then \(Q_{k,J}(n + 1) = Q_{k,J}(n) = 1\) and so,
\[
|U_{k,J}(n)| \leq \sum_{l \in L_{k,J} \cup L'_{k,J}} |1 - Q_{k,J}(l)||\tilde{\sigma}_J(n + 1 - l) - \tilde{\sigma}_J(n - l)|.
\]
Hence, by arguing as above, one deduces that
\[
|U_{k,J}(n)| \lesssim |J|([M_d(\chi_{L,J})(n)]^2 + [M_d(\chi_{L'_{k,J}})(n)]^2),
\]
where the implied constants do not depend on \(k, \ J\). Therefore, (4.55) also holds in this subcase and hence, the proof of the lemma is complete. \(\square\)

Going now back to the proof of (4.53), observe that for every \(n \in \mathbb{Z}\) one has
\[
|\hat{\tilde{c}}_{k,J}(n + 1) - \hat{\tilde{c}}_{k,J}(n)| \leq \int_J |e^{ix} - 1||\hat{\tilde{c}}_{k,J}(x)|dx \leq |J||\|c_{k,J}\|_{L^1(\mathbb{T})} \lesssim |J||b_{k,J}\|_{L^1(\mathbb{T})}
\]
and \(|\hat{\tilde{c}}_{k,J}(n)| \lesssim ||b_{k,J}\|_{L^1(\mathbb{T})}\). It thus follows from Lemma 13 that there exists an absolute constant \(C_0 > 0\) such that
\[
B_J \leq C_0(B_J^{(1)} + B_J^{(2)}),
\]
\(\square\) Springer
where

\[
B_J^{(1)} := |J| \left( \sum_{n \in \mathbb{Z}} \left[ \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \left[ M_d \left( \| b_{k,J} \|_{L^1(\mathbb{T})}^{1/2} \chi_{L_k, J} \right)(n) \right]^2 \right] \right)^{1/2}
\]

and

\[
B_J^{(2)} := |J| \left( \sum_{n \in \mathbb{Z}} \left[ \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \left[ M_d \left( \| b_{k,J} \|_{L^1(\mathbb{T})}^{1/2} \chi_{L'_k, J} \right)(n) \right]^2 \right] \right)^{1/2}.
\]

By using a version of the Fefferman–Stein theorem \cite{20} for the discrete maximal operator \( M_d \); see e.g. \cite[Theorem 1.2]{24} as well as the fact that the ‘intervals’ \( L_{k,J} \) are mutually disjoint and have cardinality \( O(|J|^{-1}) \), we deduce that

\[
B_J^{(1)} \lesssim |J| \left( \sum_{n \in \mathbb{Z}} \left[ \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \| b_{k,J} \|_{L^1(\mathbb{T})}^{2} \chi_{L_k, J}(n) \right]^2 \right)^{1/2}
\]

\[
= |J| \left( \sum_{n \in \mathbb{Z}} \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \| b_{k,J} \|_{L^1(\mathbb{T})}^{2} \chi_{L_k, J}(n) \right)^{1/2}
\]

\[
\sim |J|^{1/2} \left( \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \| b_{k,J} \|_{L^1(\mathbb{T})}^{2} \right)^{1/2},
\]

where in the above chain of inequalities the implied constants are independent of \( k \) and \( J \). Similarly, one shows that

\[
B_J^{(2)} \lesssim |J|^{1/2} \left( \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \| b_{k,J} \|_{L^1(\mathbb{T})}^{2} \right)^{1/2}
\]

and we thus have

\[
B_J \leq D_0 |J|^{1/2} \left( \sum_{k \in \{1, \ldots, N\}: |I_k| |J| > 1} \| \tilde{b}_{k,J} \|_{L^1(\mathbb{T})}^{2} \right)^{1/2}
\]

where \( D_0 > 0 \) is an absolute constant. Hence, by using the last estimate combined with (4.34), one obtains (4.53).
Therefore, by using (4.52) and (4.53), we deduce that (4.51) holds. It thus follows from (4.19), (4.48), and (4.51) that

$$B_2^{(ii)} \lesssim \frac{1}{\alpha} \| \tilde{F} \|_{L^1(\mathbb{T}; \ell^2(\mathbb{N}))}$$

and so, by combining the last estimate with (4.46), (4.47), and (4.41), we obtain (4.40). Hence, the proof of (4.28) is complete.

We have thus shown (4.24). One establishes (4.25) in a completely analogous way and hence, (4.15) holds for every \( \alpha > 0 \). Therefore, the proof of (4.5) is complete.

### 5 Variants and Remarks in the One-Dimensional Case

The argument of Tao and Wright [43] adapted to the torus, as presented in the previous section, can actually be used to handle Littlewood–Paley square functions formed with respect to finite unions of lacunary sequences in \( \mathbb{N} \). To be more specific, observe that an increasing sequence \( \Lambda \) of positive integers can be written as a finite union of lacunary sequences in \( \mathbb{N} \) if, and only if, the quantity

$$\sigma_\Lambda := \sup_{N \in \mathbb{N}} \#(\Lambda \cap \{2^{N-1}, \ldots, 2^N\})$$

(5.1)

is finite. Hence, given a finite union of lacunary sequences \( \Lambda \), if \( f \) is an arbitrary trigonometric polynomial on \( \mathbb{T} \) and \( (F_j)_{j \in \mathbb{N}} \) and \( (\tilde{F}_k)_{k \in \mathbb{N}} \) are as in the previous section, it follows that there exists an absolute constant \( A > 0 \) such that

$$\left( \sum_{k \in \mathbb{N}} |\tilde{F}_k(x)|^2 \right)^{1/2} \leq A \sigma_\Lambda^{1/2} \left( \sum_{j \in \mathbb{N}} |F_j(x)|^2 \right)^{1/2} \text{ for a.e. } x \in \mathbb{T}.$$  

(5.2)

Note that (5.2) can be regarded as the analogue of (4.6) in this case. Therefore, by arguing exactly as in Sect. 4.1, one shows that

$$\| S^{(\Lambda)}(f) \|_{L^{1,\infty}(\mathbb{T})} \lesssim \sigma_\Lambda^{1/2} \left[ 1 + \int_{\mathbb{T}} |f(x)| \log^{1/2}(e + |f(x)|) \, dx \right].$$

(5.3)

Hence, by using interpolation (where in this case, one uses an appropriate randomised version of (5.3) instead of (4.7)) and Tao’s converse extrapolation theorem [42], one deduces that \( \| S^{(\Lambda)} \|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \) is \( O((p-1)^{-3/2} \sigma_\Lambda^{1/2}) \) for \( p \in (1, 2) \). Similarly, by arguing as in Remark 9, one shows that the \( H^p_A(\mathbb{T}) \to L^p(\mathbb{T}) \) operator norm of \( S^{(\Lambda)} \) is \( O((p-1)^{-1} \sigma_\Lambda^{1/2}) \) for \( p \in (1, 2) \). We thus obtain the following theorem.
Theorem 14 There exists an absolute constant \( C_0 > 0 \) such that for every strictly increasing sequence \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) in \( \mathbb{N} \) with \( \sigma_\Lambda < \infty \) one has

\[
\sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \leq \frac{C_0}{p - 1} \sigma_\Lambda^{1/2}
\]

(5.4)

and

\[
\|S^{(\Lambda)}\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \leq \frac{C_0}{(p - 1)^{3/2}} \sigma_\Lambda^{1/2}
\]

(5.5)

for every \( 1 < p < 2 \).

If \( \Lambda \) is a lacunary sequence in \( \mathbb{N} \) with ratio \( \rho_\Lambda \in (1, 2) \) then one can easily check that

\[
\sigma_\Lambda \lesssim (\rho_\Lambda - 1)^{-1}
\]

and hence, (1.3) and (1.5) are direct corollaries of (5.4) and (5.5), respectively.

Moreover, by arguing as in Sect. 3.1, one can show that both estimates in Theorem 14 are asymptotically optimal in the sense that for every \( \sigma \in \mathbb{N} \) ‘large’, there exist strictly increasing sequences \( \Lambda_1, \Lambda_2 \) of positive integers with \( \sigma/\Lambda_i = \sigma \) \((i = 1, 2)\) such that

\[
\sigma^{1/2} \lesssim \liminf_{p \to 1^+} \left[ (p - 1) \sup_{\|f\|_{L^p(\mathbb{T})} = 1} \|S^{(\Lambda)}(f)\|_{L^p(\mathbb{T})} \right]
\]

(5.6)

and

\[
\sigma^{1/2} \lesssim \liminf_{p \to 1^+} \left[ (p - 1)^{3/2} \|S^{(\Lambda)}\|_{L^p(\mathbb{T}) \to L^p(\mathbb{T})} \right].
\]

(5.7)

5.1 Zygmund’s Classical Inequality Revisited

Let \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) be an increasing sequence that can be written as a finite union of lacunary sequences in \( \mathbb{N} \) or, equivalently, \( \sigma_\Lambda < \infty \) with \( \sigma_\Lambda \in \mathbb{N} \) being as in (5.1).

Notice that (4.1), (4.2), (5.2), and the argument on pp. 530–531 in [43] yield the following version of a classical inequality due to Zygmund (see Theorem 7.6 in Chapter XII of [45])

\[
\left( \sum_{j \in \mathbb{N}_0} |\hat{f}(\lambda_j)|^2 \right)^{1/2} \leq A \sigma_\Lambda^{1/2} \left[ 1 + \int_T |f(x)| \log^{1/2}(e + |f(x)|) \mathrm{d}x \right],
\]

(5.8)

where \( A > 0 \) is an absolute constant. Therefore, by using (5.8) and duality; see e.g. Remarque on pp. 350–351 in [8], one deduces that for every trigonometric polynomial
such that $\text{supp}(\widehat{g}) \subseteq \Lambda$ one has

$$
\|g\|_{L^p(T)} \leq C\sigma_{\Lambda}^{1/2}\sqrt{p}\|g\|_{L^2(T)} \quad \text{for all } 2 \leq p < \infty,
$$

where $C > 0$ is an absolute constant.

We remark that the exponent $r = 1/2$ in $\sigma_{\Lambda}^{1/2}$ in (5.9) cannot be improved and therefore, the exponent $r = 1/2$ in $\sigma_{\Lambda}^{1/2}$ on the right-hand side of (5.8) is sharp. Indeed, this can be shown by using the work of Bourgain [11]. To be more specific, since we assume that $\sigma_{\Lambda}/\Lambda < \infty$, we may write $\Lambda$ as a disjoint union of lacunary sequences $\Lambda_1, \ldots, \Lambda_N$ of positive integers with $\rho_{\Lambda_j} \geq 2$ for all $j = 1, \ldots, N$ and $N \sim \sigma_{\Lambda}$. Since lacunary sequences with ratio greater or equal than 2 are quasi-independent sets in $\mathbb{Z}$; see [12, Definition 4], it follows that we may decompose $\Lambda$ as a disjoint union of $N \sim \sigma_{\Lambda}$ quasi-independent sets. We thus conclude that for every finite subset $A$ of $\Lambda$ there exists a quasi-independent subset $B$ of $A$ such that

$$
\#(B) \geq N^{-1}\#(A) \sim \sigma_{\Lambda}^{-1}\#(A)
$$

and hence, (5.9) as well as its sharpness (in terms of the dependence with respect to $\sigma_{\Lambda}$) follows from [11, Lemma 1], see also pp. 101–102 in [12].

For variants of the aforementioned result of Zygmund in higher dimensions, see [3,4] and the references therein.

### 6 Higher-Dimensional Versions of Theorems 1 and 2

In this section we extend Theorem 1 to the $d$-torus. To state our result, fix a $d \in \mathbb{N}$ and consider strictly increasing sequences $\Lambda_n = (\lambda_{jn})_{jn \in \mathbb{N}_0}$ of positive integers, $n \in \{1, \ldots, d\}$. Then, the $d$-parameter Littlewood–Paley square function formed with respect to $\Lambda_n (n \in \{1, \cdots, d\})$ is given by

$$
S^{(\Lambda_1, \ldots, \Lambda_d)}(f) := \left( \sum_{j_1, \ldots, j_d \in \mathbb{N}_0} \left| \Delta_{j_1}^{(\Lambda_1)} \otimes \cdots \otimes \Delta_{j_d}^{(\Lambda_d)}(f) \right|^2 \right)^{1/2}
$$

and is initially defined over the class of all trigonometric polynomials $f$ on $T^d$.

**Theorem 15** Given a $d \in \mathbb{N}$, there exists an absolute constant $C_d > 0$ such that for every $1 < p < 2$ and for all lacunary sequences $\Lambda_n = (\lambda_{jn})_{jn \in \mathbb{N}_0}$ in $\mathbb{N}$ with ratio $\rho_{\Lambda_n} \in (1, 2)$, $n \in \{1, \ldots, d\}$, one has

$$
\sup_{\|f\|_{L^p(T^d)} = 1} \left\| S^{(\Lambda_1, \ldots, \Lambda_d)}(f) \right\|_{L^p(T^d)} \leq \frac{C_d}{(p - 1)^d} \prod_{n=1}^{d} (\rho_{\Lambda_n} - 1)^{-1/2} \quad (6.1)
$$
and
\[ \left\| S^{(\Lambda_1, \ldots, \Lambda_d)} \right\|_{L^p(T^d) \to L^p(T^d)} \leq \frac{C_d}{(p-1)^{3d/2}} \prod_{n=1}^{d} (\rho_{\Lambda_n} - 1)^{-1/2}. \] (6.2)

**Proof** We shall prove (6.1) first. To this end, the idea is to fix a probability space \((\Omega, \mathcal{A}, P)\) and show that there exists an absolute constant \(C > 0\) such that for every choice of \(\omega \in \Omega\) one has
\[ \left\| \sum_{j \in \mathbb{N}_0} r_j(\omega) \Delta_j^{(\Lambda)}(g) \right\|_{L^p(T)} \leq \frac{C}{p-1} (\rho_{\Lambda} - 1)^{-1/2} \left\| g \right\|_{L^p(T)}. \] (6.3)
for every analytic trigonometric polynomial \(g\) on \(T\). Then the proof of (6.1) is obtained by iterating (6.3).

To prove (6.3), note that by arguing as in Sect. 3.1.1 and more specifically, by using estimate (3.2) in Bourgain’s paper [13], which follows from Bourgain’s extension [10] of Rubio de Francia’s theorem [37], one deduces that there exists an absolute constant \(M > 0\) such that for every \(q \in [1, 2]\) one has
\[ \left\| h \right\|_{L^q(T)} \leq M \left\| S^{(\Lambda)}(h) \right\|_{L^q(T)} \] (6.4)
for every analytic trigonometric polynomial \(h\) on \(T\). Hence, in order to establish (6.3), fix a trigonometric polynomial \(g\) and consider the trigonometric polynomial \(h_\omega\) given by
\[ h_\omega := \sum_{j \in \mathbb{N}_0} r_j(\omega) \Delta_j^{(\Lambda)}(g). \]
Observe that (6.4) applied to \(h_\omega\) implies that
\[ \left\| \sum_{j \in \mathbb{N}_0} r_j(\omega) \Delta_j^{(\Lambda)}(g) \right\|_{L^p(T)} \leq M \left\| S^{(\Lambda)}(g) \right\|_{L^p(T)} \]
for all \(p \in (1, 2)\) and for every analytic trigonometric polynomial \(g\) on \(T\). Hence, the desired estimate (6.3) follows from the last inequality combined with (1.3). Alternatively, (6.3) can be obtained by using (4.13) and Marcinkiewicz interpolation for analytic Hardy spaces for the operator \(T_{\omega}^{(\Lambda)} := \sum_{j \in \mathbb{N}_0} r_j(\omega) \Delta_j^{(\Lambda)}\), as explained in Sect. 4.

To complete the proof of (6.1), fix a \(p \in (1, 2)\) and take an analytic trigonometric polynomial \(f\) on \(T^d\). By iterating (6.3), we get
\[ \left\| \sum_{j_1, \ldots, j_d \in \mathbb{N}_0} r_{j_1} \otimes \cdots \otimes r_{j_d}(\omega_1, \ldots, \omega_d) \Delta_j^{(\Lambda_1)}(f) \otimes \cdots \otimes \Delta_j^{(\Lambda_d)}(f) \right\|_{L^p(T^d)} \]
\[
\leq \frac{C^d}{(p - 1)^d} \left[ \prod_{n=1}^{d} (\rho_{\Lambda_n} - 1)^{-1/2} \right] \|f\|_{L^p(\mathbb{T}^d)},
\]

where \( C > 0 \) is the constant in (6.3). Hence, by using the last estimate together with multi-dimensional Khintchine’s inequality (2.5) and the density of analytic trigonometric polynomials on \( \mathbb{T}^d \) in \( (H^p_{\Lambda} (\mathbb{T}^d), \| \cdot \|_{L^p(\mathbb{T}^d)}) \), (6.1) follows.

The proof of (6.2) is similar. Indeed, by iterating (4.10), one gets

\[
\left\| \sum_{j_1, \ldots, j_d \in \mathbb{N}_0} r_{j_1} \otimes \cdots \otimes r_{j_d}(\omega_1, \ldots, \omega_d) \Delta_{j_1}(\Lambda_1) \otimes \cdots \otimes \Delta_{j_d}(\Lambda_d) (f) \right\|_{L^p(\mathbb{T}^d)}
\leq \frac{C^d}{(p - 1)^{3d/2}} \left[ \prod_{n=1}^{d} (\rho_{\Lambda_n} - 1)^{-1/2} \right] \|f\|_{L^p(\mathbb{T}^d)}
\]

for every trigonometric polynomial \( f \) on \( \mathbb{T}^d \), where \( \Lambda_n \) is a strictly increasing sequence in \( \mathbb{N} \) associated to \( \Lambda_n \) and is constructed as in Lemma 6, \( n \in \{1, \ldots, d\} \). Hence, the proof of (6.2) is obtained by using the last estimate, (2.5), the fact that for every trigonometric polynomial \( f \) on \( \mathbb{T}^d \) one has

\[
S^{(\Lambda_1, \ldots, \Lambda_d)} (f)(x) \lesssim_d S^{(\tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_d)} (f)(x) \quad (x \in \mathbb{T}^d),
\]

and the density of trigonometric polynomials on \( \mathbb{T}^d \) in \( (L^p(\mathbb{T}^d), \| \cdot \|_{L^p(\mathbb{T}^d)}) \). \( \square \)

**Remark 16** The estimates (6.1) and (6.2) in Theorem 15 can be regarded as refined versions of [7, Corollary 2] and [2, Proposition 4.1], respectively.

An adaptation of the argument presented in Sect. 3.1 to higher dimensions shows that for every choice of \( \lambda \) ‘close’ to 1+ there exists a lacunary sequence \( \Lambda = (\lambda_j)_{j \in \mathbb{N}_0} \) in \( \mathbb{N} \) with ratio \( \rho_{\Lambda} \in [\lambda, \lambda^2) \) such that

\[
(p - 1)^{-d/2} \lesssim_d \liminf_{p \to 1^+} \left[ (p - 1)^d \sup_{\|f\|_{L^p(\mathbb{T}^d)} = 1} \left\| S^{(\Lambda, \ldots, \Lambda)} (f) \right\|_{L^p(\mathbb{T}^d)} \right]
\]

\[
\leq \limsup_{p \to 1^+} \left[ (p - 1)^d \sup_{\|f\|_{H^p_{\Lambda} (\mathbb{T}^d)} = 1} \left\| S^{(\Lambda, \ldots, \Lambda)} (f) \right\|_{L^p(\mathbb{T}^d)} \right] \lesssim_d (p - 1)^{-d/2}
\]

Similarly, one deduces that (6.2) is also asymptotically optimal.

**Remark 17** By arguing as in the previous section, one shows that if \( \Lambda_n = (\lambda_j^{(n)})_{j \in \mathbb{N}_0} \) are finite unions of lacunary sequences \( (n = 1, \ldots, d) \), then

\[
\sup_{\|f\|_{L^p(\mathbb{T}^d)} = 1} \left\| S^{(\Lambda_1, \ldots, \Lambda_d)} (f) \right\|_{L^p(\mathbb{T}^d)} \lesssim_d (p - 1)^{-d} \prod_{n=1}^{d} \sigma_{\Lambda_n}^{1/2}
\]
On a Problem of Pichorides

and

\[ \left\| S^{(\Lambda_1, \ldots, \Lambda_d)} \right\|_{L^p(\mathbb{T}^d) \to L^p(\mathbb{T}^d)} \lesssim_d (p - 1)^{-3d/2} \prod_{n=1}^d \sigma_{\Lambda_n}^{1/2} \]

and that the above estimates cannot be improved in general.

7 Euclidean Variants

Let \( \Lambda = (\lambda_j)_{j \in \mathbb{Z}} \) be a countable collection of positive real numbers indexed by \( \mathbb{Z} \) such that \( \lambda_{j+1} > \lambda_j \) for all \( j \in \mathbb{Z} \) as well as

\[ \lim_{j \to -\infty} \lambda_j = 0 \quad \text{and} \quad \lim_{j \to +\infty} \lambda_j = +\infty. \]

For \( j \in \mathbb{Z} \) define the \( j \)-th ‘rough’ Littlewood–Paley projection \( P_j^{(\Lambda)} \) to be the multiplier with symbol \( \chi_{I_j \cup I_j'} \), where \( I_j := [\lambda_{j-1}, \lambda_j) \) and \( I_j' := (-\lambda_{j-1}, -\lambda_j) \).

Given a \( d \in \mathbb{N} \) and sequences \( \Lambda_1, \ldots, \Lambda_d \) as above, the corresponding \( d \)-parameter ‘rough’ Littlewood–Paley operator is given by

\[ S^{(\Lambda_1, \ldots, \Lambda_d)}_{\mathbb{R}^d}(f) := \left( \sum_{j_1, \ldots, j_d \in \mathbb{Z}} \left| P^{(\Lambda_1)}_{j_1} \otimes \cdots \otimes P^{(\Lambda_d)}_{j_d}(f) \right|^2 \right)^{1/2}. \]

The following theorem is a Euclidean version of (6.1).

Theorem 18 Given a \( d \in \mathbb{N} \), consider sequences \( \Lambda_1, \ldots, \Lambda_d \) that are as above and moreover, satisfy

\[ \sigma_{\Lambda_n} := \sup_{j \in \mathbb{Z}} \#(\Lambda_n \cap [2^{-j-1}, 2^j)) < \infty \]

for all \( n \in \{ 1, \ldots, d \} \).

Then, there exists an absolute constant \( C_d > 0 \), depending only on \( d \), such that

\[ \sup_{\|f\|_{L^p(\mathbb{R}^d)} = 1} \left\| S^{(\Lambda_1, \ldots, \Lambda_d)}_{\mathbb{R}^d}(f) \right\|_{L^p(\mathbb{R}^d)} \leq \frac{C_d}{(p - 1)^d} \prod_{n=1}^d \sigma_{\Lambda_n}^{1/2} \]

for every \( 1 < p < 2 \).

Similarly, a Euclidean version of (6.2) is the content of the following theorem.
Theorem 19  Given a $d \in \mathbb{N}$, consider sequences $\Lambda_1, \ldots, \Lambda_d$ that are as above and moreover, satisfy

$$\sigma_{\Lambda_n} := \sup_{j \in \mathbb{Z}} \#(\Lambda_n \cap [2^{j-1}, 2^j)) < \infty$$

for all $n \in \{1, \ldots, d\}$.

Then, there exists an absolute constant $C_d > 0$, depending only on $d$, such that

$$\left\| S^{(\Lambda_1, \ldots, \Lambda_d)}_{\mathbb{R}^d} \right\|_{L^p(\mathbb{R}^d) \to L^p(\mathbb{R}^d)} \leq \frac{C_d}{(p - 1)^{3d/2}} \prod_{n=1}^d \sigma_{\Lambda_n}^{1/2}$$

(7.2)

for every $1 < p < 2$.

The proofs of Theorems 18 and 19 are given in Sect. 7.1 and 7.2, respectively.

7.1 Proof of Theorem 18

Let $n \in \{1, \ldots, d\}$ be a fixed index. Note that if we consider a probability space $(\Omega, \mathcal{A}, \mathbb{P})$ and $\Lambda_n = (\lambda(n))_{j \in \mathbb{Z}}$ is as in the hypothesis of the theorem, then it follows from the work of Tao and Wright [43], see also Remark 9, that there exists an absolute constant $C_0 > 0$ such that

$$\left\| \sum_{|j_n| \leq N_n} r_{j_n}(\omega_n) P_{j_n}^{(\Lambda_n)} (f) \right\|_{L^1(\mathbb{R})} \leq C_0 \sigma_{\Lambda_n}^{1/2} \|f\|_{L^1(\mathbb{R})} \quad (f \in H_A^1(\mathbb{R}))$$

(7.3)

for every choice of $\omega_n \in \Omega$ and $N_n \in \mathbb{N}$.

We can now argue as in [7, Sect. 5]. Assume first that $p \in (1, 3/2]$ and note that by using (7.3) together with the trivial bound

$$\left\| \sum_{|j_n| \leq N_n} r_{j_n}(\omega_n) P_{j_n}^{(\Lambda_n)} \right\|_{H_A^2(\mathbb{R}) \to H_A^2(\mathbb{R})} = 1$$

and a Marcinkiewicz decomposition for functions in analytic Hardy spaces on the real line, which is due to Jones; see [25, Theorem 2], one deduces that

$$\left\| \sum_{|j_n| \leq N_n} r_{j_n}(\omega_n) P_{j_n}^{(\Lambda_n)} \right\|_{H_A^p(\mathbb{R}) \to H_A^p(\mathbb{R})} \leq \frac{A_0}{p - 1} \sigma_{\Lambda_n}^{1/2},$$

(7.4)

where $A_0 > 0$ is an absolute constant; see the proof of [7, Proposition 8]. To show that (7.4) also holds for $p \in (3/2, 2)$, one can use, e.g. (7.4) for $p = 3/2$ and duality so that one gets an appropriate $H_A^3(\mathbb{R})$ to $H_A^3(\mathbb{R})$ bound and then, as in the previous case, interpolate between this bound and (7.3).
Therefore, (7.4) holds for all $p \in (1, 2)$ and hence, by iterating (7.4) and then using multi-dimensional Khintchine’s inequality (2.5), (7.1) follows by using a standard limiting argument.

**Remark 20** By adapting the argument of Sect. 3.1 to the Euclidean setting, one can show that the exponents $r = 1/2$ in $\sigma_{A_n}^{1/2}$ in (7.1) are optimal.

### 7.2 Proof of Theorem 19

The proof of (7.2) is obtained by carefully examining and iterating Lerner’s argument that establishes [30, Theorem 1.1]. To be more precise, if for $N_1, \ldots, N_d \in \mathbb{N}$ we define $S_{N_1, \ldots, N_d}$ by

$$S_{N_1, \ldots, N_d}(f) := \left( \sum_{|j_1| \leq N_1, \ldots, |j_d| \leq N_d} \left| P_{j_1}^{(\Lambda_1)} \otimes \cdots \otimes P_{j_d}^{(\Lambda_d)}(f) \right|^2 \right)^{1/2}$$

for $f \in S(\mathbb{R}^d)$, then the proof of (7.2) will be a consequence of the following weighted estimate

$$\|S_{N_1, \ldots, N_d}\|_{L^2(\otimes_{n=1}^d w_n) \to L^2(\otimes_{n=1}^d w_n)} \leq C_d \left( \prod_{n=1}^d \sigma_{A_n}^{1/2} \right) \left[ w_1 \otimes \cdots \otimes w_d \right]^{3/2}_{A_s^{*}(\mathbb{R}^d)},$$

(7.5)

combined with an appropriate extrapolation argument, where the constant $C_d > 0$ in (7.5) depends only on $d$ and is independent of $\Lambda_1, \ldots, \Lambda_d$ and $N_1, \ldots, N_d \in \mathbb{N}$. More specifically, in [27], Kokilashvili and Meskhi extended an extrapolation result of Duoandikoetxea [17, Theorem 3.1] to the product setting; see [27, Theorem A]. In our case, to deduce (7.2) from (7.5), one needs the following $d$-parameter variant of [27, Theorem A] for tensor products of one-dimensional weights.

**Lemma 21** Let $p_0 \in [1, \infty)$ be a given exponent and let $\mathcal{F}$ be a family of pairs of non-negative functions on $\mathbb{R}^d$.

Assume that there exist an increasing function $N$ on $[0, \infty)$ and a positive constant $A_d$, depending only on $d$, such that for all $(f, g) \in \mathcal{F}$ one has

$$\|g\|_{L^{p_0}(\otimes_{n=1}^d w_n)} \leq A_d N\left( \prod_{n=1}^d [w_n]_{A_{p_0}(\mathbb{R})} \right) \|f\|_{L^{p_0}(\otimes_{n=1}^d w_n)}$$

for all $d$-tuples of $A_{p_0}$ weights $w_1, \ldots, w_d$ on $\mathbb{R}$.

Then, there exists a constant $A'_d > 0$, depending only on $d$, such that for each $p \in (1, \infty)$ one has

$$\|g\|_{L^p(\otimes_{n=1}^d u_n)} \leq A'_d K_p(u_1, \ldots, u_d) \|f\|_{L^p(\otimes_{n=1}^d u_n)}$$
for all \((f, g) \in \mathcal{F}\) and for all \(d\)-tuples of \(\Lambda_p\) weights \(u_1, \ldots, u_d\) on \(\mathbb{R}\), where for \(p < p_0\) one has

\[
K_p(u_1, \ldots, u_d) = N \left( \left[ 2 \| M_S \|_{L^p(\mathbb{R}^d)} \right]^{p_0 - p} \prod_{n=1}^{d} \left[ u_n \right]_{\Lambda_p(\mathbb{R})} \right)
\]

and for \(p > p_0\), one has

\[
K_p(u_1, \ldots, u_d) = N \left( \left[ 2 \| M_S \|_{L^p(\mathbb{R}^d)} \right]^{p - p_0} \prod_{n=1}^{d} \left[ u_n \right]_{\Lambda_p(\mathbb{R})} \right)^{p_0 - 1}.
\]

The proof of the lemma follows from an adaptation of the corresponding argument of \([17]\), as presented in \([27]\). We omit the details.

Observe now that if (7.5) holds, then (7.2) follows from Lemma 21 applied to the family \(\mathcal{F} = \{ (|f|, S_{N_1, \ldots, N_d}^{(\Lambda_1, \ldots, \Lambda_d)}(f)) : f \in S(\mathbb{R}^d) \}\) for the case of constant weights \(u_n \equiv 1\) \((n \in \{1, \ldots, d\})\), combined with (2.2). One is thus reduced to showing (7.5).

Towards this aim, for \(n \in \{1, \ldots, d\}\), define \(\tilde{\Lambda}_n := \Lambda_n \cup (2^j)_{j \in \mathbb{Z}}\) and notice that for every function \(f \in S(\mathbb{R}^d)\) one has

\[
S_{N_1, \ldots, N_d}^{(\Lambda_1, \ldots, \Lambda_d)}(f) \lesssim_d S_{N'_1, \ldots, N'_d}^{(\tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_d)}(f)
\]

for some appropriate choice of \(N'_1, \ldots, N'_d \in \mathbb{N}\). Hence, in order to establish (7.5), it suffices to prove that

\[
\left\| S_{N'_1, \ldots, N'_d}^{(\tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_d)} \right\|_{L^2(\mathbb{R}^d)} \leq C'_d \left( \prod_{n=1}^{d} \left[ u_n \right]_{\Lambda_n}^{1/2} \right) \left( \prod_{n=1}^{d} \left[ u_n \right]_{\Lambda_n}^{3/2} \right)
\]

for any \(d\)-tuple of \(A_2\) weights \(u_1, \ldots, u_d\) on \(\mathbb{R}\), where \(C'_d\) is a constant that depends only on \(d\) and not on \(\tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_d\) and \(N'_1, \ldots, N'_d \in \mathbb{N}\).

We shall argue as in \([30]\). To be more precise, to prove (7.6), one first establishes a \(d\)-parameter version of \([30, \text{Theorem 2.7}]\) for the case of tensor products of \(A_2\) weights on \(\mathbb{R}\). To state the desired estimate, we need to introduce some notation. Given dyadic lattices \(I_1, \ldots, I_d\) in \(\mathbb{R}\); see \([30, \text{Definition 2.1}]\) and a Schwartz function \(\phi\), one sets

\[
S_{\phi, I_1 \times \ldots \times I_d}(f) := \left( \sum_{k_1, \ldots, k_d \in \mathbb{Z}} \sum_{|J_1| = 2^{-k_1}} \ldots \sum_{|J_d| = 2^{-k_d}} \langle |f \ast \phi_{k_1} \ast \ldots \ast \phi_{k_d}|^2 \rangle_{J_1 \times \ldots \times J_d} \cdot \chi_{J_1 \times \ldots \times J_d} \right)^{1/2}.
\]
where for $k \in \mathbb{Z}$ we write $\phi_k(x) := 2^k \phi(2^k x)$, $x \in \mathbb{R}$. By iterating [30, Theorem 2.7], one establishes the following lemma.

**Lemma 22** There exist dyadic lattices $\mathcal{I}_1, \ldots, \mathcal{I}_d$, $l_1, \ldots, l_d \in \{1, 2, 3\}$, a function $\phi \in S(\mathbb{R})$ with supp($\hat{\phi}$) $\subseteq [-2, -1/2] \cup [1/2, 2]$, and a constant $B_d > 0$ such that for all $d$-tuples of $A_2$ weights $w_1, \ldots, w_d$ on $\mathbb{R}$ one has

$$\|f\|_{L^2(\otimes_{n=1}^d w_n)} \leq B_d \left( \prod_{n=1}^d [w_n]_{A_2(\mathbb{R})} \right)^{1/2} \sum_{l_1, \ldots, l_d \in \{1, 2, 3\}} \|S_{\phi, \mathcal{I}_1} \times \cdots \times S_{\phi, \mathcal{I}_d}(f)\|_{L^2(\otimes_{n=1}^d w_n)}$$

for all $f \in L^2(w_1 \otimes \cdots \otimes w_d)$.

As in [30, Remark 4.1], by using duality and Lemma 22, the proof of (7.5) will be complete once it is shown that there exists a constant $C'_d > 0$ such that

$$\left\| \sum_{|j_1| \leq N'_1, \ldots, |j_d| \leq N'_d} \left( \prod_{n=1}^d \sigma_{A_n} \right) \left( \prod_{n=1}^d [w_n]_{A_2(\mathbb{R})} \right)^{1/2} \right\|_{L^2(\otimes_{n=1}^d w_n)}^{2} \leq C'_d \left( \prod_{n=1}^d \sigma_{A_n} \right) A_{\mathcal{I}_1, \ldots, \mathcal{I}_d} \left[ (\psi_{j_1}, \ldots, j_d) \right]_{j_1, \ldots, j_d \in \mathbb{Z}}$$

(7.7)

for every $d$-tuple of $A_2$ weights $w_1, \ldots, w_d$ on $\mathbb{R}$ and for every collection of Schwartz functions $(\psi_{j_1}, \ldots, j_d)_{j_1, \ldots, j_d \in \mathbb{Z}}$ such that $\phi_{j_1, \ldots, j_d} \equiv 0$ whenever $|j_n| > N'_n$ for some $n \in \{1, \ldots, d\}$.

For $n \in \{1, \ldots, d\}$, write $\tilde{\mathcal{I}}_n = (\tilde{\mathcal{I}}_1)^{(n)}$, $\tilde{\mathcal{I}}_j = (\tilde{\mathcal{I}}_j)^{(n)}$ for $j \in \mathbb{Z}$. To prove (7.7), observe that by using the Cauchy–Schwarz inequality one gets

$$\left\| \sum_{|j_1| \leq N'_1, \ldots, |j_d| \leq N'_d} \left( \prod_{n=1}^d \sigma_{A_n} \right) \left( \prod_{n=1}^d [w_n]_{A_2(\mathbb{R})} \right)^{1/2} \right\|_{L^2(\otimes_{n=1}^d w_n)}^{2} \leq 4^d \left( \prod_{n=1}^d \sigma_{A_n} \right) A_{\mathcal{I}_1, \ldots, \mathcal{I}_d} \left[ (\psi_{j_1}, \ldots, j_d) \right]_{j_1, \ldots, j_d \in \mathbb{Z}},$$

where

$$A_{\mathcal{I}_1, \ldots, \mathcal{I}_d} \left[ (\psi_{j_1}, \ldots, j_d) \right]_{j_1, \ldots, j_d \in \mathbb{Z}} := \sum_{n=1}^d \sum_{k_n \in \mathbb{Z}} \sum_{\tilde{\mathcal{I}}_{j_n} \in A_{k_n}} \left\| \prod_{n=1}^d P_{j_n} (\tilde{\mathcal{I}}_{j_n}) (\psi_{j_1}, \ldots, j_d) \right\|_{L^2(\otimes_{n=1}^d \tilde{\mathcal{I}}_{j_n}, \mathcal{I}_n)}^{2}$$
and $A_{kn} := [2^{kn-1}, 2^{kn+1}) \cap [\lambda_{n} - N_{n}', \lambda_{n}')$, $n \in \{1, \ldots, d\}$. Here, as in [30], one sets

$$w_{kn, I_n} := \sum_{J_n \in I_n: |J_n| = 2 - kn} \langle w_n \rangle_{J_n} \chi_{J_n}, \quad n \in \{1, \ldots, d\}.$$ 

By using [30, Lemma 3.2] and iteration, one easily deduces that

$$\| P_{j_1}^{(\tilde{\lambda}_1)} \otimes \cdots \otimes P_{j_d}^{(\tilde{\lambda}_d)} (\psi_{j_1}, \ldots, j_d) \ast (\phi_{k_1} \otimes \cdots \otimes \phi_{k_d}) \|^2_{L^2(\otimes_{n=1}^d w_{kn, I_n})} \leq C_{d, \phi} \left( \prod_{n=1}^d (w_n)^2 \right) A^2(\mathbb{R}) \| \psi_{j_1}, \ldots, j_d \|^2_{L^2(\otimes_{n=1}^d w_n)}$$

for all $k_1, \ldots, k_d \in \mathbb{Z}$ and for every $j_{kn} \in \mathbb{Z}$ such that $\tilde{\lambda}_{j_{kn}} \subseteq A_{kn}$, $n \in \{1, \ldots, d\}$, where $C_{d, \phi} > 0$ is a constant depending only on $\phi$ and $d$. Hence, (7.7) is obtained by combining the last two estimates. Therefore, we deduce that (7.5) holds.

**Remark 23** We remark that either by adapting the modification of Lerner’s argument [30] presented above to the periodic setting or by using (7.2) (for $d = 1$) combined with transference for square functions; see [1], one obtains an alternative proof of Theorem 14 and, in particular, an alternative proof of Theorem 2.

**Remark 24** By adapting the argument of Sect. 3.1 to the Euclidean setting, one can show that the exponents $r = 1/2$ in $\sigma_{\Lambda_n}^{1/2}$ in (7.2) cannot be improved asymptotically in general.

**Remark 25** Assume that $\Lambda = (\lambda_j)_{j \in \mathbb{Z}}$ is a countable collection of non-negative real numbers satisfying the assumptions of Theorem 7.2.

Then, by arguing as in Sect. 4, where one uses a version of Tao’s converse extrapolation theorem for operators restricted to compact sets in $\mathbb{R}$; see p. 2 in [42], one can obtain a local version of (7.2) and more specifically,

$$\left\| S^{(\Lambda)}_R \right\|_{L^p(K) \to L^p(K)} \lesssim K \sigma_{\Lambda_n}^{1/2} (p - 1)^{-3/2} (1 < p < 2)$$

for every compact subset $K$ of the real line.

**Acknowledgements** The author would like to thank Prof. James Wright for several discussions on matters related to the paper [43], as well as Dr. Alan Sola and Prof. James Wright for their comments on an earlier version of this manuscript.
