Generating Ontologies from Templates: A
Rule-Based Approach for Capturing Regularity

Abstract

We present a second-order language that can be used to succinctly specify ontologies in a consistent and transparent manner. This language is based on ontology templates (OTTR), a framework for capturing recurring patterns of axioms in ontological modelling. The language, and our results are independent of any specific DL.

We define the language and its semantics, including the case of negation-as-failure, investigate reasoning over ontologies specified using our language, and show results about the decidability of useful reasoning tasks about the language itself. We also state and discuss some open problems that we believe to be of interest.

1 Introduction

The phenomenon of frequently occurring structures in ontologies engineering (OE) has received attention from a variety of angles. One of the first accounts is given in [6], where repeated versions of general conceptual models are identified. Similar observations gave rise to the notion of Ontology Design Patterns (ODP) as abstract descriptions of best practices in OE [15, 4, 22]. Another view, emphasizing common ontological distinctions, led to the emergence of Upper Ontologies which aim to categorize general ideas shareable across different domains [16]. Orthogonal to such conceptual patterns, the existence of syntactic regularities in ontologies has been noted and some aspects of their nature have been analyzed [30, 29, 31].

In this paper, we propose a new language that allows expressing patterns of repeated structures in ontologies. This language is rule-based and has both a model-theoretic and a fixpoint semantics, for which we show that they coincide. In contrast to other rule languages “on top of” DLs, in this language, firing a rule results in the addition of TBox and/or ABox axioms, with the goal to succinctly describe ontologies, thereby making them more readable and maintainable.

Given that DL ontologies are sets of axioms, an ontology provides no means to arrange its axioms in a convenient manner for ontology engineers. In particular, it is not possible to group conceptually related axioms or indicate interdependencies between axioms. While ontology editors such as Protégé¹ display an ontology through a hierarchy of its entities, conceptual interdependencies between axioms are hidden and the underlying structural design of an ontology remains obfuscated.

Example 1.1 Consider the ontology

\[
\mathcal{O}_1 = \{ \text{Jaguar} \sqsubseteq \text{Animal}, \quad \text{Jaguar} \sqsubseteq \forall \text{hasChild}.\text{Jaguar}, \quad (1) \\
\text{Tiger} \sqsubseteq \text{Animal}, \quad \text{Tiger} \sqsubseteq \forall \text{hasChild}.\text{Tiger}, \quad (2) \\
\text{Lion} \sqsubseteq \text{Animal}, \quad \text{Lion} \sqsubseteq \forall \text{hasChild}.\text{Lion} \} \quad (3)
\]

Then, an ontology editor will group the entities Jaguar, Tiger and Lion under Animal according to their class hierarchy.

However, \(\mathcal{O}_1\) contains no indication that every subclass \(X\) of Animal can have only children of the same class \(X\). Assume this regularity is no coincidence but a desired pattern that should hold for any subclass of Animal. Currently, ontology engineers have no means of expressing or enforcing such a pattern other than

¹https://protege.stanford.edu/
dealing with the ontology as a whole, inspecting all axioms separately, and making
necessary changes manually.

Expressing patterns such as in Example 1.1 explicitly has a potential to reveal
some aspects of the intentions for the design of an ontology.

**Example 1.2** Consider the ontology
\[ \mathcal{O}_2 = \{ \text{Jaguar} \sqsubseteq \text{Animal}, \text{Tiger} \sqsubseteq \text{Animal}, \text{Lion} \sqsubseteq \text{Animal} \} \]

In addition, consider the rule
\[ g : \{ ?X \sqsubseteq \text{Animal} \} \rightarrow \{ ?X \sqsubseteq \forall \text{hasChild}.?X \}, \]

where ?X is a variable. We can interpret the body of this rule as a query which, when
evaluated over the ontology \( \mathcal{O}_2 \), returns substitutions for ?X. These substitutions
can then be used to instantiate the axioms in the head of the rule. Firing the above
rule over \( \mathcal{O}_2 \) would add all those resulting axioms to \( \mathcal{O}_2 \), thereby reconstructing \( \mathcal{O}_1 \)
from Example 1.1.

In the following, we will call such rules *generators*. The possible benefits of
generators are threefold. Firstly, \( \mathcal{O}_2 \) in combination with \( g \) makes a statement about all subconcepts of Animal that *the type of an animal determines the type of its children*. This is a kind of meta-statement about
concepts which a user of an ontology can usually only learn by inspecting (many)
axioms in an ontology. Secondly, \( \mathcal{O}_2 \) in combination with \( g \) is easier to maintain
and extend compared to \( \mathcal{O}_1 \), where a user would have to manually ensure that
the meta-statement continues to be satisfied after new concepts have been added.
Thirdly, conceptual relationships captured in a generator such as \( g \) are easy to reuse
and can foster interoperability between ontologies in the spirit of ontology design
patterns.

We close this section with more elaborate examples to demonstrate the benefits
generators such as \( g \) can provide.

### 1.1 Examples

**Example 1.3 (Composition)** Assume we want to model typical roles in groups of
social predatory animals. One such a role would be that of a hunter. A challenge for
representing such knowledge is that different collective nouns are used for different
animals, e.g. a group of lions is called a “pride”, a group of wild dogs is called a
“pack”, a group of killer whales is called a “pod”, etc. Therefore, a mechanism that
can conveniently iterate over all these group formations would be beneficial.

Consider the following query \( Q_1 : \)
\[ Q_1 = \{ ?X \sqsubseteq \text{Animal}, \] (4)\[ \]\[ ?X \sqsubseteq \exists \text{eats.Animal}, \] (5)\[ \]\[ ?X \sqsubseteq \exists \text{hunts.Animal}, \] (6)\[ \]\[ ?Y \sqsubseteq \text{SocialGroup}, \] (7)\[ \]\[ ?X \sqsubseteq \exists \text{socialisesIn.?Y}, \] (8)\[ \]\[ ?Y \sqsubseteq \exists \text{hasMember.?X}, \] (9)\[ \]\[ \text{socialisesIn} \equiv \text{hasMember}^{-} \} \] (10)\[

Lines 4–6 bind the variable \(?X\) to a predatory animal. Line 7 binds the variable \(?Y\) to a type of social group and lines 8–10 associate a particular type of animal with its respective social group. Given the bindings for \(?X\) and \(?Y\) it is straightforward to express that a particular type of predator \(?X\) is a hunter in its respective social group, namely: \(?Y \sqsubseteq \exists \text{hasHunter.?X}\). A generator such as in Example 1.2 could capture this relationship:

\[ g_1 : Q_1 \rightarrow \{ ?Y \sqsubseteq \exists \text{hasHunter.?X} \} \]

**Example 1.4 (Extension)** Extending generator \(g_1\) from Example 1.3 to capture more specialised knowledge is straightforward. Consider predatory ants of the family Formicidae. These ants generally live in colonies with an elaborate social organisation consisting of workers, drones, queens, etc. First, we extend query \(Q_1\) with the following axioms:

\[ \]

\[ Q_2 = Q_1 \cup \{ ?X \sqsubseteq \text{Formicidae}, \] (11)\[ \]\[ ?Z \sqsubseteq ?Y \] (12)\[ \]\[ ?X \sqsubseteq \exists \text{socialisesIn.?Z} \} \] (13)\[

Axiom 11 requires \(?X\) to bind to a type of Formicidae, e.g. \(?X = \text{SafariAnt}\). According to query \(Q_1\), the variable \(?Y\) binds to a general SocialGroup, e.g. \(?Y = \text{AntColony}\). Then, axiom 12 binds \(?Z\) to a more specialised subgroup of a \(?Y\). Finally, axiom 13 ensures that this subgroup \(?Z\) is associated with \(?X\). So for \(?X = \text{SafariAnt}\) we get \(?Z = \text{SafariAntColony}\).

Next, we can specify the generator to add all desired axioms based on matches of query \(Q_2\) specialised for ants:

\[ g_2 : Q_2 \rightarrow \]
\{ ?Z \sqsubseteq \exists \text{hasHunter.?X}, \] (14)\[ \]\[ ?Z \sqsubseteq \exists \text{hasWorker.?X}, \] (15)\[ \]\[ ?Z \sqsubseteq \exists \text{hasDrone.?X}, \] (16)\[ \]\[ ?Z \sqsubseteq \exists \text{hasQueen.?X} \} \]

Note how the body and head of generator \(g_1\) from Example 1.3 have been reused and extended only by set unions.

**Example 1.5 (Negative Guards)** Often, general relationships are subject to exceptions. While most ants hunt and feed cooperatively, there are some genera of ants,
e.g. Myrmecia, that do not. Therefore, \( g_2 \) in Example 1.4 would generate an undesired axiom, namely \( \text{MyrmeciaAntColony} \sqsubseteq \text{hasHunter} \cdot \text{MyrmeciaAnt} \). This motivates guards in the body of generators that may not only specify positive constraints but also negative ones:

\[
Q_3 = Q_2 \cup \{ \text{not } \exists X \sqsubseteq \text{MyrmeciaAnt}, \\
\text{not } \neg \exists Z \sqsubseteq \text{MyrmeciaAntColony} \}
\]

\[ g_3: Q_3 \rightarrow \{ \exists Z \sqsubseteq \exists \text{hasHunter} \cdot X, \\
\exists Z \sqsubseteq \exists \text{hasWorker} \cdot X, \\
\exists Z \sqsubseteq \exists \text{hasDrone} \cdot X, \\
\exists Z \sqsubseteq \exists \text{hasQueen} \cdot X \} \]

One might argue that the effect of negative guards could also be achieved by positive guards using negated concepts in DL, i.e. \( \exists X \sqsubseteq \neg \text{MyrmeciaAnt} \) instead of \( \neg \exists X \sqsubseteq \text{MyrmeciaAnt} \). However, this approach would necessitate the introduction of a potentially large number of axioms of type \( \exists X \sqsubseteq \neg \text{MyrmeciaAnt} \) in the given ontology. This can be avoided by using \( g_3 \).

Another advantage of negative guards is the possibility to explicitly express default assumptions for lack of better knowledge. An ant colony of a certain genus usually consists of only ants of this genus, e.g.

\[
\text{SafariAntColony} \sqsubseteq \forall \exists \text{hasMember} \cdot \text{SafariAnt}. \quad (14)
\]

However, some genera of ants are social parasites that enslave other ant species. In such a case, the default assumption about the homogeneity of an ant colony is wrong and the axiom 14 should not be added.

\[
Q_4 = \{ \exists X \sqsubseteq \text{Ant}, \\
\exists Y \sqsubseteq \text{AntColony}, \\
\exists Y \sqsubseteq \exists \text{hasMember} \cdot X, \\
\exists Z \sqsubseteq \text{Ant}, \\
\exists X \sqsubseteq \neg \exists \neg Z, \\
\text{not } \exists X \sqsubseteq \exists \text{enslaves} \cdot Z, \\
\text{not } \exists Y \sqsubseteq \exists \text{hasMember} \cdot Z \}
\]

\[ g_4: Q_4 \rightarrow \{ \exists Y \sqsubseteq \forall \exists \text{hasMember} \cdot X \} \]

**Example 1.6 (Recursion)**  
Contagious diseases may be transmitted between animals sharing a habitat. Overlapping habitats of infected animals may result in a propagation of diseases across habitats.

Assume there is an overlap between habitats \( H_1, H_2, H_3 \) such that there is no overlap between \( H_1 \) and \( H_3 \), \( H_{12} \) describes the overlap between \( H_1 \) and \( H_2 \), and \( H_{23} \) describes the overlap between \( H_2 \) and \( H_3 \) (see Figure 1). Then, a disease infected animal living in \( H_1 \) may affect an animal in \( H_2 \) which in turn may affect an animal
in $H_3$. Such an iterative process may be captured by repeatedly applying a single generator.

Consider the following query:

$$Q_5 = \{ ?X \sqsubseteq \text{Animal}, \quad (15) $$
$$ ?Y \sqsubseteq \text{Animal}, \quad (16) $$
$$ ?D \sqsubseteq \text{ContagiousDisease}, \quad (17) $$
$$ ?H \sqsubseteq \text{Habitat}, \quad (18) $$
$$ ?X \sqsubseteq \exists \text{suffersFrom}.?D, \quad (19) $$
$$ ?Y \sqsubseteq \forall \text{isSusceptibleTo}.?D, \quad (20) $$
$$ ?X \sqsubseteq \exists \text{livesIn}.?H, \quad (21) $$
$$ ?Y \sqsubseteq \exists \text{livesIn}.?H \} \quad (22) $$

Axioms 19 and 20 express the requirements for a disease to be transmitted between animals while axioms 21 and 22 capture the requirement of a shared environment. Using query $Q_5$, we can represent the propagation of a disease between animals across habitats:

$$g_5 : Q_5 \rightarrow \{ ?Y \sqsubseteq \exists \text{suffersFrom}.?D \} \quad \square$$

Clearly, the generation of an instance of $?Y \sqsubseteq \exists \text{suffersFrom}.?D$ could yield a new match for $Q_5$ in the body of $g_5$. Therefore, generator $g_5$ has to be applied repeatedly until a fixpoint is reached.

**Example 1.7 (Encapsulation)** Inspecting the queries $Q_1, Q_2$, and $Q_3$ in Examples 1.3–1.5, it is apparent that different parts in the queries correspond to different conceptual ideas. For example, in query $Q_1$ the axioms can be grouped into ones about predators and others about social groups. Such a grouping would provide valuable information for an ontology engineer to indicate conceptual relationships between
certain sets of axioms:

\[
\begin{align*}
\{?X \sqsubseteq \text{Animal}, \\
?X \sqsubseteq \exists \text{eats.Animal}, \\
?X \sqsubseteq \exists \text{hunts.Animal}\} & \quad \text{Predator} \\
\{?Y \sqsubseteq \text{SocialGroup}, \\
?X \sqsubseteq \exists \text{socialisesIn.?Y}, \\
?Y \sqsubseteq \exists \text{hasMember.?X}, \\
\text{socialisesIn} \equiv \exists \text{hasMember}\} & \quad \text{Social Group}
\end{align*}
\]

Reasonable ontology templates [38, 14], OTTR for short, introduced a framework for indicating such conceptual relationships. A template is defined as a named ontology with a set of variables. The variables can be instantiated with concept and role expressions to yield a set of valid axioms. Moreover, templates may be composed to give rise to more complex templates. Choosing intention-revealing names for templates and composing appropriately named templates may improve ontology comprehension by making the structural design of an ontology visible.

A template, i.e., a set of axioms with variables, can also be interpreted as a query, asking for concept and role expressions in an existing ontology that match the pattern represented by the template. These expressions can then, in principle, be fed into a different template to produce new axioms. This idea captures conceptual interdependencies between templates or, more generally, axiomatic patterns.

Clearly, it is straightforward to integrate OTTR as part of a preprocessing step into our rule language. This has not only the potential to foster the reuse of conceptually related sets of axioms in an intention-revealing manner, but can also to further improve the maintainability of generators by the principle of information hiding. A change in a template will be propagated automatically to all instances of the use of the template.

\[2\] Preliminaries

Let \(N_I, N_C,\) and \(N_R\) be sets of individual, concept, and role names, each containing a distinguished subset of individual, concept, and role variables \(V_I, V_C,\) and \(V_R.\) A concept (resp. role) is either a concept name (resp. role name) or a concept expression (resp. role expression) built using the usual DL constructors [2]. Since we do not distinguish between TBoxes and ABoxes, an axiom is either an assertion of the form \(C(a)\) or \(R(a, b)\) for a concept \(C,\) role \(R,\) and individual names \(a, b\) or an inclusion statement \(C \subseteq D\) for concepts or roles \(C\) and \(D.\) A theory is a (possibly infinite) set of axioms, whereas an ontology is a finite set of axioms. A set \(\mathcal{L}\) of individuals, concepts, and roles is called a language.

A template \(T\) is an ontology, and we write \(T(V)\) for \(V \subseteq V_I \cup V_C \cup V_R\) the set of variables occurring in \(T.\) For the sake of brevity, we occasionally omit the variable set \(V\) when it is either clear from context or nonvital to the discussion. Templates can be instantiated by applying a substitution to them. A substitution \(\sigma\) is a function that maps individual, concept, and role variables to individuals, concepts, and roles respectively. We require that substitutions respect the type of a variable, so that the result of instantiating a template is a well-formed ontology. For \(\mathcal{L}\) a language, an
\(\mathcal{L}\)-substitution is one whose range is a subset of \(\mathcal{L}\). The \(\mathcal{L}\)-evaluation of \(T\) over \(\mathcal{O}\), written \(\text{eval}(T, \mathcal{O}, \mathcal{L})\), is the set of substitutions defined as follows:

\[
\text{eval}(T, \mathcal{O}, \mathcal{L}) = \{\sigma \text{ an } \mathcal{L}\text{-substitution} | \mathcal{O} \models T\sigma\},
\]

where \(T\sigma\) is the instantiation of \(T\) with \(\sigma\). Furthermore, we define \(\text{eval}(\emptyset, \mathcal{O}, \mathcal{L})\) to be the set of all \(\mathcal{L}\)-substitutions.

Finally, we say that an ontology \(\mathcal{O}\) is weaker than \(\mathcal{O}'\) if \(\mathcal{O}' \models \mathcal{O}\), and strictly weaker if the reverse does not hold.

## 3 Generators and GBoxes

In this section we define the syntax and semantics of generators and GBoxes and discuss some examples.

**Definition 3.1** A generator \(g\) is an expression of the form \(T_B(V_B) \rightarrow T_H(V_H)\), for \(T_B(V_B), T_H(V_H)\) templates with \(V_H \subseteq V_B\). \(T_B\) and \(T_H\) are respectively called the body and head of \(g\), and we write \(B(g)\) and \(H(g)\) to denote them.

**Example 3.2** \(g\): \{\(?X \sqsubseteq \text{Animal}\) \rightarrow \{\(?X \sqsubseteq \forall \text{hasChild} . ?X\)\} is a generator, with a single variable \(?X\).

Next, we define the semantics for generators and sets of generators based on entailment to ensure that generators behave independent of the syntactic form of an ontology. In this choice we diverge from the work done on OTTR [38], as OTTR template semantics is defined syntactically.

**Definition 3.3** Let \(g\) be a generator. A theory \(\mathcal{O}\) satisfies \(g\) wrt. \(\mathcal{L}\) if, for every \(\mathcal{L}\)-substitution \(\sigma\) such that \(\mathcal{O} \models T_B\sigma\), we have \(\mathcal{O} \models T_H\sigma\).

**Example 3.4** Consider the generator \(g\) from Example 3.2. The theory \(\mathcal{O}_1 = \{\text{Turtle} \sqsubseteq \text{Mammal}, \text{Mammal} \sqsubseteq \text{Animal}, \text{Turtle} \sqsubseteq \forall \text{hasChild} . \text{Turtle}, \text{Mammal} \sqsubseteq \forall \text{hasChild} . \text{Mammal}\}\) satisfies \(g\), while the theory \(\mathcal{O}_2 = \{\text{Turtle} \sqsubseteq \text{Mammal}, \text{Mammal} \sqsubseteq \text{Animal}\}\) does not.

A set \(G\) of generators is called a \(\text{GBox}\). Furthermore, we define the set \(B(G)\) (resp. \(H(G)\)) as the set of all bodies (resp. heads) occurring in \(G\), i.e., they are sets of ontologies.

**Definition 3.5** Let \(G\) be a \(\text{GBox}\), \(\mathcal{O}\) an ontology, and \(\mathcal{L}\) a language. The expansion of \(\mathcal{O}\) and \(G\) in \(\mathcal{L}\), written \(\text{Exp}(G, \mathcal{O}, \mathcal{L})\), is the smallest set of theories \(\mathcal{O}'\) such that

1. \(\mathcal{O}' \models \mathcal{O}\),
2. \(\mathcal{O}'\) satisfies every \(g \in G\) wrt. \(\mathcal{L}\), and
3. \(\mathcal{O}'\) is entailment-minimal, i.e. there is no \(\mathcal{O}''\) strictly weaker than \(\mathcal{O}'\) satisfying (1) and (2).

We call the theories in \(\text{Exp}(G, \mathcal{O}, \mathcal{L})\) expansions. This definition corresponds to the model-theoretic Datalog semantics, with consequence rather than set inclusion. Since axioms can be rewritten to be subset-incomparable, entailment-minimality is used rather than subset minimality. For example, consider \(\{A \sqsubseteq B, B \sqsubseteq C\}\) and \(\{A \sqsubseteq C\}\): the second one is not a subset of the first one, but weaker than it.
Example 3.6 Recall the generator \( g \) from Example 3.2, and let \( G \) be a GBox consisting of \( g \) alone. Let \( \mathcal{O} = \{ \text{Turtle} \sqsubseteq \text{Mammal}, \text{Mammal} \sqsubseteq \text{Animal} \} \), and let \( \mathcal{L} \) be the set of all concept names. Then \( \{ \text{Turtle} \sqsubseteq \text{Mammal}, \text{Mammal} \sqsubseteq \text{Animal}, \text{Turtle} \sqsubseteq \forall \text{hasChild}. \text{Turtle}, \text{Mammal} \sqsubseteq \forall \text{hasChild}. \text{Mammal} \} \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \).

4 Results

We show that the semantics defined in the previous section coincides with a fixpoint-based one, investigate the role played by the language \( \mathcal{L} \), and investigate generators with negated templates.

Theorem 4.1 For every \( G, \mathcal{O}, \) and \( \mathcal{L} \), we have that any two \( \mathcal{O}_1, \mathcal{O}_2 \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) are logically equivalent.

Proof Assume for contradiction that this is not the case. Then there exist \( \mathcal{O}_1, \mathcal{O}_2 \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) such that \( \mathcal{O}_1 \not\models \mathcal{O}_2 \) because otherwise, one would be strictly weaker than the other, contradicting the definition of \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \). In particular, there exist \( \alpha \) and \( \beta \) such that:

\[
\begin{align*}
\mathcal{O}_1 &\models \alpha, \\
\mathcal{O}_2 &\not\models \alpha \quad (23)
\end{align*}
\]

\[
\begin{align*}
\mathcal{O}_2 &\models \beta, \\
\mathcal{O}_1 &\not\models \beta \quad (24)
\end{align*}
\]

Now consider the set of axioms \( T = \{ \tau \mid \mathcal{O}_1 \models \tau \land \mathcal{O}_2 \models \tau \} \). Since both \( \mathcal{O}_1 \) and \( \mathcal{O}_2 \) entail \( \mathcal{O} \) and satisfy every \( g \in G \), it is clear that so does \( T \). However,

\[
\begin{align*}
T &\not\models \mathcal{O}_1 \quad (25) \\
T &\not\models \mathcal{O}_2 \quad (26)
\end{align*}
\]

due to the entailments \( \alpha \) (Eq. 23) and \( \beta \) (Eq. 24). Hence \( T \) is strictly weaker than both \( \mathcal{O}_1 \) and \( \mathcal{O}_2 \). This contradicts the initial assumption of \( \mathcal{O}_1, \mathcal{O}_2 \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \).

Hence applying a GBox \( G \) to an ontology \( \mathcal{O} \) results in a theory that is unique modulo equivalence, but not necessarily finite. As a consequence, we can treat \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) as a single theory when convenient.

Our definition of \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) is strictly semantic, i.e., does not tell us how to identify any \( \mathcal{O}' \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \). In order to do that, we define a 1-step expansion.

Definition 4.2 The 1-step expansion of \( \mathcal{O} \) and \( G \) in \( \mathcal{L} \), written \( \text{1Exp}(G, \mathcal{O}, \mathcal{L}) \), is defined as follows:

\[
\text{1Exp}(G, \mathcal{O}, \mathcal{L}) = \mathcal{O} \cup \bigcup_{T_s \rightarrow T_h \in G} \{ T_h \sigma \mid \sigma \in \text{eval}(T_h, \mathcal{O}, \mathcal{L}) \}.
\]

In other words, we add to \( \mathcal{O} \) all instantiated heads of all generators applicable in \( \mathcal{O} \). Of course, this extension may result in other generators with other substitutions becoming applicable, and so on recursively.

Lemma 4.3 If \( \mathcal{O}_1 \subseteq \mathcal{O}_2 \), then \( \text{1Exp}(G, \mathcal{O}_1, \mathcal{L}) \subseteq \text{1Exp}(G, \mathcal{O}_2, \mathcal{L}) \).

Proof Simple consequence of Def. 3.3 and \( \text{eval}(B(g), \mathcal{O}_1, \mathcal{L}) \subseteq \text{eval}(B(g), \mathcal{O}_2, \mathcal{L}) \) for any generator \( g \).
**Definition 4.4** The $n$-step expansion of $\mathcal{O}$ and $G$ in $\mathcal{L}$, written $\text{1Exp}^n(G, \mathcal{O}, \mathcal{L})$, is defined as follows:

$$\text{1Exp}^n(G, \mathcal{O}, \mathcal{L}) = \underbrace{\text{1Exp}(\ldots \text{1Exp}(G, \mathcal{O}, \mathcal{L}) \ldots)}_{n\text{ times}}.$$ 

We use $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ to denote the least fixpoint of $\text{1Exp}(G, \mathcal{O}, \mathcal{L})$. 

**Theorem 4.5** For finite $\mathcal{L}$, the least fixpoint $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ exists and belongs to $\text{Exp}(G, \mathcal{O}, \mathcal{L})$. 

**Proof** Since $\mathcal{L}$ is finite, the set of all $\mathcal{L}$-substitutions for the variables occurring in $G$ is finite. Let $\Sigma_\mathcal{L}$ be this set, and consider the set $H = \mathcal{O} \cup \bigcup_{T_\sigma \rightarrow T_\nu \in G, \sigma \in \Sigma_\mathcal{L}} T_\nu \sigma$, that is, $\mathcal{O}$ as well as all axioms obtained from the heads of instances of generators in $G$. This set is also finite. 

It is easily verified that $\text{1Exp}$ is an operator on the powerset of $H$. Since $\text{1Exp}$ is monotone, the least fixpoint $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ exists, and belongs to $\text{Exp}(G, \mathcal{O}, \mathcal{L})$ by construction. 

In other words, our fully semantic definition of $\text{Exp}(G, \mathcal{O}, \mathcal{L})$ coincides with the operational semantics based on the fixpoint computation.

**Size of the fixpoint** For a generator $g$ with variables $V$, there are at most $|\mathcal{L}|^{|V|}$ different $\mathcal{L}$-substitutions. The size of the fixpoint is therefore bounded by $|G| \times |\mathcal{L}|^n$, where $n$ is the maximum number of variables in any $g \in G$. In the worst case we need to perform entailment checks for all of them, adding one instantiation at a time to $\mathcal{O}$. Hence determining $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ involves up to $(|G| \times |\mathcal{L}|^n)^2$ entailment checks. For finite $\mathcal{L}$ and provided we have a fixed upper bound for $n$, determining $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ involves a polynomial number of entailment tests and results in a $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ whose size is polynomial in the size of $G$ and $\mathcal{L}$.

**Finite vs infinite $\mathcal{L}$**

The next examples illustrate the difficulties an infinite language $\mathcal{L}$ can cause. The first example shows how an infinite $\mathcal{L}$ can lead to infinite expansions.

**Example 4.6** Consider the ontology $\mathcal{O} = \{A \sqsubseteq \exists R.B\}$, the generator $g : \{?X \sqsubseteq \exists R.?Y\} \rightarrow \{?X \sqsubseteq \exists R.?Y\}$, and $\mathcal{L}$ the set of all $\mathcal{L}$-concept expressions. Clearly, $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ is infinite, and so is each expansion in $\text{Exp}(G, \mathcal{O}, \mathcal{L})$. 

The next example shows that this does not necessarily happen.

**Example 4.7** Consider the ontology $\mathcal{O} = \{\exists R.A \sqsubseteq A\}$, the generator $g : \{\exists R.?X \sqsubseteq ?X\} \rightarrow \{\exists R.?X \sqsubseteq \exists R.?X\}$, and $\mathcal{L}$ the set of all $\mathcal{L}$-concept expressions. Clearly, $\text{1Exp}^*(G, \mathcal{O}, \mathcal{L})$ is infinite, but there is a finite (and equivalent) ontology to this fixpoint in $\text{Exp}(G, \mathcal{O}, \mathcal{L})$, namely $\mathcal{O}$ itself. 

While having to explicitly specify $\mathcal{L}$ may seem to be cumbersome, it is not very restrictive. In fact, it is easy to show that, for finite languages, generators can be rewritten to account for concepts, roles, or individuals that are missing from a given language by grounding the generators.
Definition 4.8 Let \( g : T_B \to T_H \) be a generator, and \( \mathcal{L} \) a finite language. The \( \mathcal{L} \)-grounding of \( g \) is the finite set of generators \( \{ T_B \sigma \to T_H \sigma \mid \sigma \text{ an } \mathcal{L}-substitution \} \).

Using \( \mathcal{L} \)-grounding, we can compensate for a smaller language \( \mathcal{L}_1 \subsetneq \mathcal{L}_2 \) by \( \mathcal{L}_1 \)-grounding generators, thereby proving the following theorem.

Theorem 4.9 Let \( \mathcal{L}_1 \subseteq \mathcal{L}_2 \) be finite languages. For every GBox \( G \) there exists a GBox \( G' \) such that, for every \( O, O_1, O_2 \) we have that \( O_1 \in \text{Exp}(G', O, \mathcal{L}_1) \) and \( O_2 \in \text{Exp}(G, O, \mathcal{L}_2) \) implies \( O_1 \equiv O_2 \).

Proof Take \( G' \) to be the union of the \( \mathcal{L}_2 \)-groundings of every generator in \( G \).

Of course, grounding all the generators is a very wasteful way of accounting for a less expressive language. A more clever rewriting algorithm should be possible: for example, if we allow binary conjunctions of names in \( \mathcal{L}_2 \) but not in \( \mathcal{L}_1 \), we can add copies of each generator where we replace variables \(?X\) with \(?X \cap ?X_2\).

4.1 GBox containment and equivalence

Having defined GBoxes, we now investigate a suitable notion for containment and equivalence of GBoxes.

Definition 4.10 (\( \mathcal{L} \)-containment) Let \( G_1 \) and \( G_2 \) be GBoxes, and \( \mathcal{L} \) a language. \( G_1 \) is \( \mathcal{L} \)-contained in \( G_2 \) (written \( G_1 \preceq \mathcal{L} G_2 \)) if \( \text{Exp}(G_2, O, \mathcal{L}) \models \text{Exp}(G_1, O, \mathcal{L}) \) for every ontology \( O \).

The following lemma relating the entailment of theories and the entailment of expansions holds as a direct consequence of the monotonicity of description logics.

Lemma 4.11 Let \( G \) be a GBox, \( T, T' \) two theories and \( \mathcal{L} \) a language. If \( T \models T' \) then \( \text{Exp}(G, T, \mathcal{L}) \models \text{Exp}(G, T', \mathcal{L}) \).

Furthermore, the following is a rather straightforward consequence of the definition of the semantics of generators.

Lemma 4.12 Let \( T \) be a theory, \( G \) a GBox, \( O \) an ontology, and \( \mathcal{L} \) a language. If \( T \models O \) and \( T \) satisfies every generator \( g \in G \) then \( T \models \text{Exp}(G, O, \mathcal{L}) \).

Using Lemmas 4.11 and 4.12, \( \mathcal{L} \)-containment can be shown to be decidable, and in fact efficiently so, using a standard freeze technique from database theory.

Theorem 4.13 Let \( G_1 \) and \( G_2 \) be GBoxes, and \( \mathcal{L} \) a language. \( G_1 \) is \( \mathcal{L} \)-contained in \( G_2 \) if and only if \( \text{Exp}(G_2, T_B, \mathcal{L}) \models T_H \) for every \( T_B \to T_H \in G_1 \).

Proof The only-if direction follows directly. For the other direction, by Lemma 4.12 we need to show that if \( \text{Exp}(G_2, T_B, \mathcal{L}) \models T_H \) for all \( T_B \to T_H \in G_1 \) then for any ontology \( O \)

\[
\text{Exp}(G_2, O, \mathcal{L}) \models g \quad \text{for all } g \in G_1, \quad (27)
\]

\[
\text{Exp}(G_2, O, \mathcal{L}) \models O. \quad (28)
\]

By Lemma 4.12, (27) and (28) imply \( \text{Exp}(G_2, O, \mathcal{L}) \models \text{Exp}(G_1, O, \mathcal{L}) \), which is the definition of \( G_1 \) being \( \mathcal{L} \)-contained in \( G_2 \). (28) is an immediate consequence of the definition of the expansion, hence we only need to show (27).
In the following we slightly abuse notation: $\text{Exp}(G, \mathcal{O}, \mathcal{L})$ for a GBox $G$, ontology $\mathcal{O}$ and language $\mathcal{L}$ shall refer to an ontology as opposed to a set of possible expansions; by Theorem 4.1, they are all logically equivalent.

Let $T_B \rightarrow T_H \in G_1$ be fixed but arbitrary. Furthermore, let $\sigma \in \text{eval}(T_B, \text{Exp}(G_2, \mathcal{O}, \mathcal{L}))$. Then, by the definition of eval,$$
\text{Exp}(G_2, \mathcal{O}, \mathcal{L}) \models T_B \sigma. \quad (*)
$$Applying Lemma 4.11 to (*) yields $\text{Exp}(G_2, \text{Exp}(G_2, \mathcal{O}, \mathcal{L}), \mathcal{L}) = \text{Exp}(G_2, \mathcal{O}, \mathcal{L})$ (otherwise $\text{Exp}(G_2, \mathcal{O}, \mathcal{L})$ would not be an expansion) and hence

$$\text{Exp}(G_2, \mathcal{O}, \mathcal{L}) \models \text{Exp}(G_2, T_B \sigma, \mathcal{L}). \quad (29)$$
Thus what remains is to show that

$$\text{Exp}(G_2, T_B \sigma, \mathcal{L}) \models T_H \sigma, \quad (30)$$
since (29) and (30) together yield

$$\text{Exp}(G_2, \mathcal{O}, \mathcal{L}) \models T_H \sigma. \quad (**)$$
which together with (*) implies that $\text{Exp}(G_2, \mathcal{O}, \mathcal{L})$ satisfies $T_B \rightarrow T_H$.

Using compositionality of $\mathcal{L}$-substitutions and the iterative fixpoint construction of the expansion, it is straightforward to show that

$$\text{Exp}(G_2, T_B \sigma, \mathcal{L}) \models \text{Exp}(G_2, T_B, \mathcal{L}) \sigma. \quad (31)$$
By the assumption of the theorem, $\text{Exp}(G_2, T_B, \mathcal{L}) \models T_H$ which in turn implies that $\text{Exp}(G_2, T_B, \mathcal{L}) \sigma \models T_H \sigma$. This together with (31) yields

$$\text{Exp}(G_2, T_B \sigma, \mathcal{L}) \models (\text{Exp}(G_2, T_B, \mathcal{L}) \sigma \models T_H \sigma), \quad (32)$$
thus proving (30) and thereby (**), as desired. $\blacksquare$

It follows that $\mathcal{L}$-containment is decidable for arbitrary $\mathcal{L}$ (even infinite), since we can restrict ourselves to the language of all subexpressions of $B(G_1)$. Furthermore, the complexity is the same as that of computing an expansion of a GBox.

### 4.2 GBoxes with negation

In this section we introduce negation-as-failure to GBoxes. We extend the definition of the expansions defined in Section 3, define suitable notions of semi-positive GBoxes and semantics for stratified GBoxes, and prove the corresponding uniqueness results.

To do so, a generator is now a rule of the form $T_B^+(V_1), \text{not } T_B^-(V_2) \rightarrow T_H(V_3)$, for $T_B^+(V_1), T_B^-(V_2), T_H(V_3)$ templates with $V_3 \subseteq V_1 \cup V_2$. For the sake of notational simplicity, we restrict ourselves here to generators with at most one template in the negative body. It is worth noting, however, that all definitions and results in this
section are immediately transferable to generators with multiple templates in the
negative bodies (multiple templates in the positive body can of course be simply
merged into a single template).

The following definition, together with Definition 3.5 of \( \text{Exp}(\mathcal{O}, \mathcal{L}) \), provides
a minimal model semantics for GBoxes with negation:

**Definition 4.14** An ontology \( \mathcal{O} \) satisfies a generator \( g : T^+_B(V_1), \text{not } T^-_B(V_2) \rightarrow T_H(V_3) \)
with respect to \( \mathcal{L} \) if, for every \( \sigma \in \text{eval}(T^+_B, \mathcal{O}, \mathcal{L}) \cup \text{eval}(T^-_B, \mathcal{O}, \mathcal{L}) \),
we have \( \mathcal{O} \models T_H \sigma \). □

Unsurprisingly, adding negation results in the loss of uniqueness of the expansion \( \text{Exp}(\mathcal{O}, \mathcal{L}) \) (cf. Theorem 4.1), as illustrated by the following example.

**Example 4.15** Let \( \mathcal{L} = \{A, B, C, s\} \), \( \mathcal{O} = \{A(s)\} \) and \( G = \{A(?X), \text{not } B(?X) \rightarrow C(?X)\} \). Then \( \text{Exp}(\mathcal{O}, \mathcal{L}) \) contains the two non-equivalent expansions \( \{A(s), B(s)\} \) and \( \{A(s), C(s)\} \). □

Next, we extend the definition of the 1-step expansion operator from Definition 4.2 to support negation. However, as Example 4.17 will show, a fixpoint does not always correspond to an expansion in \( \text{Exp}(\mathcal{O}, \mathcal{L}) \).

**Definition 4.16** The 1-step expansion of \( \mathcal{O} \) and \( G \) in \( \mathcal{L} \) of a GBox \( G \) with negation,
written \( \text{1Exp}^{-}(\mathcal{O}, \mathcal{L}) \), is defined as follows:

\[
\text{1Exp}^{-}(\mathcal{O}, \mathcal{L}) = \mathcal{O} \cup \bigcup_{T^+_B \cup \text{not } T^-_B \rightarrow T_H \in G} \{ T_H \sigma \mid \sigma \in \text{eval}(T^+_B, \mathcal{O}, \mathcal{L}) \cup \text{eval}(T^-_B, \mathcal{O}, \mathcal{L}) \}.
\]

**Example 4.17** Consider the ontology \( \mathcal{O} = \{\text{Single} \sqsubseteq \text{Person}, \text{Spouse} \sqsubseteq \text{Person}, \text{Single} \sqsubseteq \neg \text{Spouse}, \text{Person(Maggy)}\} \) and the following GBox \( G \)

\[
G = \{ \{\text{Person(?X)}\}, \text{not } \{\text{Single(?X)}\} \rightarrow \{\text{Spouse(?X)}\}, \\
\{\text{Person(?X)}\}, \text{not } \{\text{Spouse(?X)}\} \rightarrow \{\text{Single(?X)}\} \}
\]

The expansion \( \text{Exp}(\mathcal{O}, \mathcal{L}) \) contains the two non-equivalent ontologies \( \mathcal{O} \cup \{\text{Single(Maggy)}\} \) and \( \mathcal{O} \cup \{\text{Spouse(Maggy)}\} \). Furthermore, the iterated fixpoint \( \text{1Exp}^{-}\) (\( \mathcal{O}, \mathcal{L} \) is \( \mathcal{O} \cup \{\text{Single(Maggy)}, \text{Spouse(Maggy)}\} \)) is not a minimal model as it is not entailment-minimal. □

A natural question arising is whether we can identify or even characterize GBoxes with negation that have a unique expansion. To this end, we define suitable notions of semi-positive GBoxes and stratified negation. These are based on the notion of multiple templates affecting others, as formalized next.

**Definition 4.18** Let \( \mathcal{L} \) be a language, \( S = \{S_1, \ldots, S_k\} \) a set of templates, \( \mathcal{O} \) an
ontology, and \( T \) a template. We say that \( S \) activates \( T \) with respect to \( \mathcal{O} \) in \( \mathcal{L} \) if there exist \( \mathcal{L} \)-substitutions \( \sigma_1, \ldots, \sigma_k \) such that \( \mathcal{O} \cup \bigcup S_i \sigma_i \models T \sigma \) for some \( \mathcal{L} \)-substitution \( \sigma \). For brevity we omit \( \mathcal{O} \) if they are clear from the context. □

In contrast to standard Datalog with negation, the entailment of a template in the body of a generator is not solely dependent on a single generator with a corresponding head firing. Instead, multiple generators might need to fire and interact with \( \mathcal{O} \) in order to entail a body template. Hence we use the set \( S \) of templates in the definition of activation.
Example 4.19 Consider the GBox containing \( g_1 : T_1(\sigma X) \rightarrow \{ ?X \subseteq A \} \), \( g_2 : T_2(\sigma Y) \rightarrow \{ ?Y \subseteq B \} \) and \( g_3 : \text{not} \{ ?Z \subseteq A \cap B \} \rightarrow T_3(\sigma Z) \). Then \( H(g_1) \) and \( H(g_2) \) activate \{ ?Z \subseteq A \cap B \} with respect to any \( \mathcal{O} \) and \( \mathcal{L} \), indicating that the firing of \( g_3 \) depends on the combined firing of \( g_1 \) and \( g_2 \).

Activation can then be used to define a notion of semi-positive GBoxes, which is analogous to semi-positive Datalog programs.

Definition 4.20 (Semi-positive GBoxes) Let \( G \) be a GBox with negation, \( \mathcal{L} \) a language, and \( \mathcal{O} \) an ontology. \( G \) is called semi-positive w.r.t. \( \mathcal{O} \) and \( \mathcal{L} \) if no negative body template \( T_B^− \) of a generator \( g \in G \) is activated by \( H(G) \).

As seen in Example 4.15, even semi-positive GBoxes result in multiple non-equivalent expansions. In that example, neither the ontology \( \mathcal{O} \) nor any possible firing of \( G \) can yield \( B(s) \). As such, we wish to restrict the theories in \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) to containing only facts derivable from \( \mathcal{O} \) and \( G \). To that end, the following definition suitably restricts the entailment of expansions.

Definition 4.21 Let \( G \) be a GBox, \( \mathcal{O} \) an ontology, and \( \mathcal{L} \) a finite language. We say that an expansion \( \mathcal{O}' \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) is justifiable w.r.t. \( (G, \mathcal{O}, \mathcal{L}) \) if the following holds: if \( \mathcal{O}' \models T \sigma \) for some template \( T \) and substitution \( \sigma \), then \( \mathcal{O} \models T \sigma \) or \( H(G) \) activates \( T \sigma \) with respect to \( \mathcal{O} \) and \( \mathcal{L} \). We write simply \( \mathcal{O}' \) is justifiable when \( G, \mathcal{O} \), and \( \mathcal{L} \) are clear from the context.

Using this notion, we can show that, indeed, a GBox being semi-positive implies that its semantics is unambiguous when restricted to justifiable expansions.

Theorem 4.22 Let \( G \) be a semi-positive GBox, \( \mathcal{O} \) an ontology, and \( \mathcal{L} \) a finite language. Then the fixpoint \( (1\text{Exp}^{-})(G, \mathcal{O}, \mathcal{L}) \) exists, is the unique fixpoint of \( 1\text{Exp}^{-} \), and is contained in \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \).

Proof Since \( 1\text{Exp}^{-}(G, \mathcal{O}, \mathcal{L}) \) is an inflationary operator and \( \mathcal{L} \) is finite, there exists an iterative fixpoint \( \mathcal{O}' = (1\text{Exp}^{-})(G, \mathcal{O}, \mathcal{L}) \). By construction, \( \mathcal{O}' \) satisfies \( \mathcal{O} \) and all generators \( g \in G \) and is justifiable w.r.t. \( (G, \mathcal{O}, \mathcal{L}) \). We simultaneously prove uniqueness and membership in \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) by showing that \( \mathcal{O}' \models \mathcal{O}' \) for an arbitrary justifiable expansion \( \mathcal{O}' \in \text{Exp}(G, \mathcal{O}, \mathcal{L}) \). Let \( \mathcal{O}_i = \mathcal{O} \) and \( \mathcal{O}_i = 1\text{Exp}^{-}(G, \mathcal{O}, \mathcal{L}) \) for \( i \geq 1 \), then \( \mathcal{O} = \mathcal{O}_0 \subseteq \ldots \subseteq \mathcal{O}_k = \mathcal{O}^* \) for some \( k \). Assume \( \mathcal{O}_1 \models T \sigma \) for some \( \mathcal{L} \)-substitution \( \sigma \) and \( T \in H(G) \). Then either \( \mathcal{O} \models T \sigma \) (in which case \( \mathcal{O}' \models T \sigma \)) or there exists a generator

\[
T_B^+, \not T_B^- \rightarrow T
\]

such that \( \sigma \in \text{eval}(T_B^+, \mathcal{O}, \mathcal{L}) \) and \( \sigma \notin \text{eval}(T_B^-, \mathcal{O}, \mathcal{L}) \). Since \( G \) is semi-positive, \( H(G) \) cannot activate \( T_B^- \), i.e., there exists no set of generators that, together with the ontology \( \mathcal{O} \), could fire in a way that would entail \( T_B^- \sigma \). Since \( \mathcal{O}' \) is entailment-minimal and justifiable, it must be the case that \( \mathcal{O}' \models T_B^- \sigma \) and hence \( \mathcal{O}' \models T \sigma \). Thus, \( \mathcal{O}' \models \mathcal{O}_1 \).

The same argument can be applied inductively to show that \( \mathcal{O}' \models \mathcal{O}_i \) for \( i \geq 1 \), thus showing \( \mathcal{O}' \models \mathcal{O}^* \). Since \( \mathcal{O}' \) was chosen arbitrarily, this proves both the uniqueness and membership claims.

The following is a direct corollary of the proof of Theorem 4.22.

Corollary 4.23 Let \( G \) be a semi-positive GBox, \( \mathcal{O} \) and ontology and \( \mathcal{L} \) a finite language. All justifiable ontologies in \( \text{Exp}(G, \mathcal{O}, \mathcal{L}) \) are logically equivalent.
For a GBox to be semi-positive is a very strong requirement. Next, we introduce the notion of a stratified GBox: this does not ensure that all expansions are equivalent, but it ensures that we can determine one of its expansions by expanding strata in the right order. Again, we use $H(G)$ to denote the set of templates in heads of generators in $G$, and $B(G)$ for the set of templates in (positive or negative) bodies of generators in $G$.

**Definition 4.24 (Stratification)** Let $Ł$ be a language and $𝒪$ an ontology. A GBox $G$ is stratifiable w.r.t. $𝒪$ and $Ł$ if there exists a function $ν : H(G) ∪ B(G) → \mathbb{N}$ such that, for every generator $T^+_B$, $\textbf{not } T^-_B → T_H \in G$ the following holds:

1. $ν(T_H) ≥ ν(T^+_B)$,
2. $ν(T_H) > ν(T^-_B)$,
3. for every $⊆$-minimal $S_1 ⊆ H(G)$ that activates $T^+_B$, $ν(T^+_B) ≥ \max S \in S_1 ν(S')$,
4. for every $⊆$-minimal $S_2 ⊆ H(G)$ that activates $T^-_B$, $ν(T^-_B) > \max S \in S_2 ν(S')$.

The first two conditions in the previous definition are analogous to stratified Datalog, which intuitively states that a body literal must be evaluated (strictly, in the case of negative literals) before head literals. The second two conditions tailor the stratification to generators: generators allow for more interaction amongst their components. As opposed to Datalog, multiple heads combined might be needed to entail a body template. Thus, a body template must be defined in a higher stratum than any possible set of templates that could entail it.

Following this definition, a stratification $ν$ of a GBox $G$ w.r.t. an ontology $𝒪$ gives rise to a partition $G^1_v, \ldots, G^k_v$ of $G$, where each generator $g : T^+_B, \textbf{not } T^-_B → T_H$ is in the stratum $G^v(T_H)$.

For a GBox $G$, an ontology $𝒪$ and a language $Ł$, we can define the precedence graph $G_{𝒪,Ł}$ as follows: nodes are the templates occurring in $G$ and

1. if $T^+_B, \textbf{not } T^-_B → T_H$ is in $G$, then $G_{𝒪,Ł}$ contains the positive edge $(T^+_B, T_H)$ and the negative edge $(T^-_B, T_H)$;
2. for a template $T$ that occurs in the positive (resp. negative) body of a generator and any $⊆$-minimal set $\{S_1, \ldots, S_k\} \subseteq H(G)$ that activates $T$ w.r.t. $𝒪$ and $Ł$, $G_{𝒪,Ł}$ contains the positive (resp. negative) edges $(S_i, T)$ for $1 ≤ i ≤ k$.

We then get the following classification of stratified GBoxes, the proof of which is entirely analogous to the Datalog case.

**Proposition 4.25** Let $Ł$ be a language and $𝒪$ an ontology. A GBox $G$ is stratifiable w.r.t. $𝒪$ and $Ł$ iff its precedence graph $G_{𝒪,Ł}$ has no cycle with a negative edge.

Given such a stratification, we can thus define a semantics for stratified negation.

**Definition 4.26 (Stratified semantics)** Let $𝒪$ be an ontology, $Ł$ a language, and $G$ a GBox stratifiable w.r.t. $𝒪$ and $Ł$. For a stratification $ν$ of $G$ and the induced partition $G^1_v, \ldots, G^k_v$ of $G$, we define $𝒪^{v}_{strat}(G, Ł)$ as follows:

1. $𝒪^1_v = 𝒪$,
2. $𝒪^j_v = 1Exp^*(G^{j-1}, 𝒪^{j-1}, Ł)$ for $1 < j ≤ k$, 

15
Theorem 4.27 Let $\mathcal{O}$ be an ontology, $\mathcal{L}$ a finite language, and $G$ be a GBox stratifiable w.r.t. $\mathcal{O}$ and $\mathcal{L}$. Then $\mathcal{O}_{\text{strat}}(G, \mathcal{O}, \mathcal{L})$ exists, is independent of the choice of $\nu$, and contained in $\text{Exp}(G, \mathcal{O}, \mathcal{L})$.

Proof Let $G_1^\nu, \ldots, G_k^\nu$ be the partitioning of $G$ w.r.t. to a stratification $\nu$. By Definition 4.24, each $G_i^\nu$ is a semi-positive GBox. Hence Theorem 4.22 guarantees the existence of $\mathcal{O}_{\text{strat}}(G, \mathcal{O}, \mathcal{L})$. By construction $\mathcal{O}_{\text{strat}}(G, \mathcal{O}, \mathcal{L})$ satisfies $\mathcal{O}$ and all generators in $G$. Furthermore, there cannot exist an ontology $\mathcal{O}'$ such that $\mathcal{O}_{\text{strat}}(G, \mathcal{O}, \mathcal{L}) \vDash \mathcal{O}'$ satisfying $\mathcal{O}$ and all generators in $G$, as this would contradict the entailment-minimality of the $\mathcal{O}_i^\nu$.

The proof for the independence of the stratification $\nu$ is entirely analogous to the Datalog case: the strongly connected components of $\mathcal{G}_{G, \mathcal{O}, \mathcal{L}}$ provide the most granular stratification, which can then be used to prove the equivalence of all stratifications (cf. [1] for a proof for stratified Datalog).

Remark 4.28 It is worth noting that, although the stratified semantics provides a unique model, stratified GBoxes do not necessarily have a unique expansion. For example, the GBox from Example 4.15 is stratifiable yet has multiple distinct expansions. Moreover, just as in Datalog, there exist nonstratified GBoxes that have a unique expansion.

5 Related work

When combining rules with DL ontologies, the focus has thus far primarily been on (1) encoding ontology axioms in rules for efficient query answering and (2) expanding the expressivity of ontologies using rules. In contrast, GBoxes are designed as a tool for ontology specification by describing instantiation dependencies between templates.

Datalog\textsuperscript{±} [5] falls into the first category: it provides a formalism for unifying ontologies and relational structures. Datalog\textsuperscript{±} captures ontology axioms as rules, and these cannot “add” new axioms.

dl-programs [13] and DL-safe rules [34] fall into the second category: dl-programs add nonmonotonic reasoning by means of stable model semantics, whereas DL-safe rules allow for axiom-like rules not expressible in standard DL. However, none of these formalisms adds new TBox axioms to the ontology.

Tawny-OWL\textsuperscript{2} and the Ontology Pre-Processing Language\textsuperscript{3} (OPPL) are formalism for manipulating OWL ontologies [27, 12]. While OPPL was designed to capture patterns and regularities in ontologies, Tawny-OWL is a more general programmatic environment for authoring ontologies that includes powerful support for ontology design patterns. It is part of future work to see whether GBoxes can be faithfully implemented in Tawny-OWL (OPPL lacks the recursion required).

Another question is whether metamodeling in DL, in particular the encoding scheme from [18] can be faithfully captured by (an extension of) GBoxes: this would require replacing axioms in $\mathcal{O}$ with others which is currently not supported.

\textsuperscript{2}https://github.com/phillord/tawny-owl
\textsuperscript{3}http://oppl2.sourceforge.net/index.html
Ontology Design Patterns (ODPs) have been proposed to capture best practices for developing ontologies \cite{15, 4}, inspired by Software Design Patterns. While some ODPs are easily expressible in GBoxes, it is part of ongoing work to investigate extensions required to capture others.

Reasonable Ontology Templates \cite{38, 14} (OTTR) provide a framework for macros in OWL ontologies, based on the notion of templates. In contrast to GBoxes, “matching” of templates is defined syntactically and non-recursively, but they can be named and composed to give rise to more complex templates.

The Generalized Distributed Ontology, Modelling and Specification Language (GDOL) \cite{24} is a formalism facilitating the template-based construction of ontologies from a wide range of logics. In addition to concepts, roles, and individuals, parameters may be ontologies which act as preconditions for template instantiation: for a given substitution, the resulting parameter ontology must be satisfiable in order to instantiate the template. Thus these preconditions serve only as a means to restrict the set of allowed instantiations of a template, whereas in GBoxes, an ontology triggers such substitutions.

6 Future work

We have presented first results about a template-based language for capturing recurring ontology patterns and using these to specify larger ontologies. Here, we list some areas that we would like to investigate in the future.

Finite representability In general, the semantics of GBoxes is such that the expansion of a GBox and ontology can be infinite if the substitution range given by $\mathcal{L}$ is infinite. A natural question arising is whether/which other mechanisms can ensure that some expansion is finite, and how can we compute such a finite expansion? Furthermore, given $G$, $\mathcal{O}$, $\mathcal{L}$, when can we decide whether an ontology in $\text{Exp}(G, \mathcal{O}, \mathcal{L})$ is finite?

Controlling substitutions So far, we have only considered entailment for generators when determining matching substitutions. Consider the ontology $\mathcal{O} = \{A \sqsubseteq B, B \sqsubseteq C\}$ and the template $?X \sqsubseteq C$. The resulting substitutions include concepts $A$ and $B$, but also a multitude of possibly unwanted, redundant concepts, e.g., $\{A \cap A, A \cap B, \ldots\}$. Hence restricting substitutions to “reasonable” or possible “parametrizable” (e.g., maximally general) ones is part of future work.

Entailment problems for ontologies with GBoxes The expansion of a Gbox over an ontology is itself an ontology and can be used as such for standard reasoning tasks. A question of interest is whether/how reasoning on the input ontology and GBox directly, without computing an expansion, can improve reasoning efficiency.

Furthermore, there are plenty of reasoning tasks about GBoxes which naturally reduce to reasoning tasks over ontologies. For example, checking whether a single generator $g : T_B \rightarrow T_H$ always leads to inconsistency is equivalent to checking whether $T_B \cup T_H$ is inconsistent. This generalizes to similar questions over entire GBoxes: To check whether there exists an ontology $\mathcal{O}$ such that every generator

\footnote{http://ottr.xyz}
g in a GBox $G$ fires, it suffices to check that the union of the generators’ bodies is consistent.

However, there are also global properties of Gboxes that do not reduce to individual templates. For example, do two GBoxes $G_1$ and $G_2$ specify equivalent ontologies? While Section 4.1 contains some results about such problems, we believe there is more to do here.

**Extensions to generators** Another area of future work is motivated by our preliminary analysis of logical ontology design patterns [17]. We found that a number of rather straightforward, seemingly useful such pattern require some form of ellipses and/or maximality. Consider, for example, the role closure pattern on the role hasTopping: if $\mathcal{O}$ entails that $\text{MyPizza} \sqsubseteq \exists\text{hasTopping}.X_1 \cap \ldots \exists\text{hasTopping}.X_n$ and $n$ is maximal for pairwise incomparable $X_i$, then we would like to automatically add $\text{MyPizza} \sqsubseteq \forall\text{hasTopping}.(X_1 \sqcup \ldots \sqcup X_n)$. Extending generators to capture some form of ellipses or unknown number of variables and maximality conditions on substitutions for variables will be part of future work.

For GBoxes to be indeed intention revealing, we will also support named generators and named sets of axioms in the body or the head of generators, as in OTTR [38].
