Acute ischemic stroke following Hump-nosed viper envenoming; first authenticated case

Vijayabala jeevagan1*, Thashi Chang2 and Christeine Ariaranee Gnanathasan2

Abstract
Hump-nosed pit viper (Genus Hypnale) is a medically important venomous snake in Sri Lanka and Southwestern India which causes significant morbidity and mortality. Envenoming of this snake results in hemostastic dysfunction, thrombotic microangiopathy, acute kidney injury and death. This case describes an authenticated first case of ischemic stroke in a 65 year old male following envenoming by Hhypnale in Sri Lanka.

Introduction
Hump-nosed vipers (Hypnale hypnale) (Figure 1) are traditionally considered as moderately venomous snakes. It is the commonest cause of venomous snakebites in Sri Lanka accounting for 22 to 77% of all snakebites [1-3]. Varying degrees of local effects, hemostastic dysfunction, microangiopathic haemolysis, acute kidney injury and death have been reported following H.hypnale envenomation [1]. In the past decade several cases of ischaemic stroke following Russell viper and Saw scale viper envenoming have been reported [4,5]. We report the first case of ischaemic stroke following H.hypnale envenoming.

Case report
A 65-year-old farmer presented with pain and swelling of his foot following a hump-nosed viper bite. The culprit snake was killed and brought for identification. There was no evidence of systemic envenoming and the 20 minute-whole blood clotting time (20-WBCT) was normal. However, 24 hours later he developed sudden onset left-sided hemiparesis with a muscle power of 3/5, exaggerated tendon reflexes and an extensor plantar response on the left. This was followed by a declining urine output and the development of intractable hiccups. He has been on atorvastatin and aspirin for stable ischaemic heart disease. He did not have hypertension or diabetes mellitus. He has not smoked tobacco for 10 years.

A plain CT scan of the brain (Figure 2) showed an acute infarct in right deep parietal region. His hemoglobin was 13.2 g/dl, white cell count was 15.6 x 10^9/l (neutrophils 80%) and the platelet count was 154 x 10^9/l. The 20-WBCT, prothrombin time, thrombin time and partial thromboplastin time with kaolin tests were monitored periodically during hospital stay and all found to be normal. His D-dimer level was 750 ng/ml (110-250 ng/ml). His electrocardiogram (ECG), transthoracic echocardiogram, lipid profile, fasting plasma glucose, duplex scan of carotids and thrombophilic screening (including anticardiolipin antibody, lupus anticoagulation and genetic screening for inherited thrombophilias) were normal. However, his serum creatinine progressively increased to 348 μmol/l. His highest blood urea was 20.6 mmol/l (2.9-8.2 mmol/l). He had no features of dehydration and repeated fluid challenges failed to restore urine out put.

He was treated with supportive care. His urine out put gradually improved without renal replacement therapy and the serum creatinine returned to normal after 5 days. He was discharged home a week later with an out-patient plan for stroke rehabilitation.

Discussion
Cerebral infarction following snake bite envenoming is uncommon. Arterial thrombotic complications including ischemic strokes have been reported following Russel viper envenoming in Sri Lanka [6], but not following hump-nosed viper bites. Our patient developed cerebral infarction 48 hours following hump-nosed viper bite. When considering his age and history of ischemic heart disease it could be a coincidental event. However the presence of potent procoagulants in hump-nosed pit viper venom, made us to consider a possible etiological role of hump-nosed viper envenoming for the cerebral infarction. Furthermore the onset of acute ischemic stroke coincided
with the onset of acute kidney injury, which indicated that active venom was present in substantial amounts to damage his kidneys. Elevated D-dimer in our patient is compatible with increased activation of the procoagulant and fibrinolytic mechanisms. In our patient pre-existing atherosclerosis might act as a predisposing factor in the mechanism of H.hypnale venom induced thrombotic occlusion.

Clinical and preclinical studies have shown that *H.hypnale* venom possess strong procoagulant, haemorrhagic and necrotic activities through the presence of phospholipase A2, hyaluronidase, L-amino acid oxidase, thrombin-like enzymes, arginine esterase and various proteases [7-10]. Arginine esterase hydrolase, a thrombin-like enzyme activates clotting factors V and X of the intrinsic and common coagulation pathways leading to thrombin formation and intravascular deposition of fibrin causing vascular occlusion. Furthermore, direct action of the venom on vascular endothelial cells causes vasospasm that may play a role in arterial occlusion [11,12]. Phospholipase A2 is a potent vasodilator that can cause acute hypotension and watershed brain infarctions, but this was not the case in our patient.

It is therefore plausible that the hump-nosed viper envenoming was the primary mechanism of vascular occlusion and stroke in our patient, but systematic studies are required to establish a cause-effect relationship. It is curious that although hump-nosed viper venom possesses the potential for vascular occlusion, there were no previous reports of stroke following envenoming. It is possible that stroke following hump-nosed viper bite is a result of a multifactorial process that depends on several factors such as the dose and composition of the venom and an underlying predisposition such as critical cerebral atherosclerosis, or that minor strokes in clinically silent areas of the brain were unrecognized.

To date, there is no effective antivenom for the treatment of hump-nosed viper envenoming. However, if strokes are increasingly recognized following hump-nosed viper bites, an antivenom will be required to prevent thrombotic complications as was shown with a substantial reduction of thrombotic complications in patients treated with antivenom following *Bothrops lanceolatus* envenoming [13]. This case report is intended to increase the vigilance for arterial thrombosis following hump-nosed viper envenomation.

**Consent**

Written informed consent was obtained from the patient for publication of this Case report and accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal.

**Competing interests**

The authors declare that they have no competing interests.

**Authors’ contributions**

All authors were involved in the management of the patient. VJ prepared the initial manuscript. AG and TC were involved in clinical decision making and they reviewed the manuscript with regard to scientific data. All authors read and approved the final manuscript.
