Abstract

Purpose of the review: Vesicoureteral reflux (VUR) is a common pathology encountered in pediatric urology. If left untreated, this condition can lead to infectious complications, hypertension and loss of renal function by scars. There is a trend for minimally invasive procedures to minimise treatment-related complications. Endoscopic subureteral injection of bulking agent in the treatment of VUR is an example of minimally invasive options. Several bulking agents have been studied and the perfect agent has not yet been discovered. Polyacrylamide hydrogel is a relatively new agent used to treat VUR and its use will be reviewed.

Recent findings: Three modern studies from a Canadian group have evaluated the use of polyacrylamide hydrogel for endoscopic injection to treat VUR. The first study reported a cure rate of 81.2% without major complication. In the second study, injection of polyacrylamide hydrogel was compared to dextranomer hyaluronic acid and no significant difference was observed, with overall success rate of 73.1% and 77.5% respectively. The third trial evaluated the long-term efficacy and safety of polyacrylamide hydrogel with a 36-month follow-up. Overall success at 3 months was 70.7% and no patient had de novo hydronephrosis or calcification of the agent at 36 months.

Conclusion: Polyacrylamide hydrogel seems to be a safe and effective alternative bulking agent in the treatment of VUR. The contribution from other centers to validate those data would be valuable.

Introduction

Vesicoureteral reflux (VUR) is frequently encountered in pediatric urology practice and overall estimated prevalence is between 1 and 3%¹,². The clinical correlation of retrograde flow of urine with pyelonephritis was first described in the 1950s-1960s by Hutch³. Nowadays, renal scarring and loss of renal function due to VUR with UTI is well established. Moreover, the leading cause of hypertension in children and young adult is renal scarring or dysplasia secondary to VUR⁴. The objectives to manage this pathology aim to prevent recurrent febrile UTIs, prevent renal injury and minimize the morbidity associated with different treatment options and follow-up⁵. Management options are: active surveillance, continuous antibiotic prophylaxis, endoscopic injections of bulking agents and open, laparoscopic or robotic ureteral reimplantation⁶,⁷.

Endoscopic injection of bulking agents has been the subject of several publications during the last three decades and is now a well-accepted surgical option⁷-¹⁰. In 1984, Puri and O’Donnell reported for the first time, treatment of VUR in piglet by...
intravesical injection of polytetrafluoroethylene (PTFE, Teflon®)\textsuperscript{11}. Several bulking agents have been studied since then, including dextranomer hyaluronic acid (Dx/HA, Deflux®)\textsuperscript{12}, polyacrylate-polyalcohol copolymer (PPC, Vantris®)\textsuperscript{13}, polydimethylsiloxane (Macroplastique®)\textsuperscript{14}, polytetrafluoroethylene (PTFE, Teflon®)\textsuperscript{15}, bovine collagen\textsuperscript{16}, calcium hydroxyapatite\textsuperscript{17} and autologous materials like chondrocytes\textsuperscript{18}, fat\textsuperscript{19} and blood\textsuperscript{19,20}. More recently, polyacrylamide hydrogel (PAHG, Bulkamid®) has been evaluated for the treatment of VUR by endoscopic injection\textsuperscript{21}. The perfect bulking agent has not yet been identified, but should be biocompatible, nontoxic, non-antigenic, non-migratory, causing minimal inflammation, no calcification and keeping its shape and volume\textsuperscript{22}. This article will review the use of polyacrylamide hydrogel as an alternative bulking agent in endoscopic treatment of children with VUR.

**Endoscopic Treatment of VUR**

Endoscopic injection of bulking agent is an attractive option for surgeons and patients/family. This procedure is less invasive than ureteral reimplantation, the operative time is shorter, no incision is needed and the intervention is usually made as an outpatient procedure. Endoscopic injection of biocompatible agent is believed to reduce reflux by adding a wall support to the ureter and narrowing the ureterovesical junction, without causing obstruction\textsuperscript{6}. In a randomized clinical trial, Garcia-Aparicio et al. concluded that endoscopic injection of Dx/HA and Cohen's ureteral reimplantation were of similar effectiveness at five years follow-up\textsuperscript{23}. Several studies compared the efficacy of ureteral reimplantation vs endoscopic injection in VUR, but conclusions remain controversial, especially for low-grade VUR\textsuperscript{23-25}. In general, ureteral reimplantation offers higher success rates than endoscopic injection but comes with more morbidities.

O'Donnell and Puri described the Subureteral Teflon Injection (STING) technique in 1984\textsuperscript{15}. In this technique, a bulking agent was injected 2-3 mm below the ureteral orifice with an 18-gauge needle through a 14 French cystoscope. In 2004, Kirsh et al. introduced the Hydrodistension Implantation Technique (HIT) where a submucosal injection is made within the ureteral orifice at the 6 o'clock position\textsuperscript{26}. Nowadays, the double HIT technique is the most popular among urologists\textsuperscript{27}. In this method, the first injection is made within the ureteral tunnel, reducing the lumen proximally, and a second injection is performed in the distal tunnel to narrow the ureteral orifice\textsuperscript{28}. If needed, additional injections with the STING technique can be made after a double HIT method\textsuperscript{28}. Studies have shown better results with HIT and double HIT techniques, but a greater volume of bulking agents was needed, further increasing the cost of the procedure\textsuperscript{27-31}.

### Polyacrylamide Hydrogel as an Alternative Bulking Agent for VUR

In 2001, dextranomer hyaluronic acid (Dx/HA), commonly called Deflux®, obtained FDA approval for endoscopic treatment of VUR and became the most widely used bulking agent\textsuperscript{7,8}. Success rate are ranging between 68% and 92% and better success rates correlate with lower grade of VUR\textsuperscript{7}. A systematic review conducted by Routh et al. in 2010 revealed an overall success rate of 77%, which means that about one quarter of treated patients will need additional procedures\textsuperscript{32}. PAHG has been widely injected around the urethra for the treatment of female stress urinary incontinence. A systematic review conducted by Kasi et al. concluded that it was an effective and safe treatment option\textsuperscript{22}. Treatment of VUR by endoscopic injection of PAHG obtained approval in Canada in October 2017, which is currently the only country to have given this approval\textsuperscript{33}. Three contemporary studies have evaluated the use of PAHG injections in endoscopic treatment in VUR\textsuperscript{21,34,35}.

Cloutier et al. in 2013 was the first group to publish pediatric management of VUR with PAHG in the English scientific literature\textsuperscript{21}. In this series, 40 patients (30 females, 10 males) underwent endoscopic injection of PAHG to treat VUR. Children with unilateral or bilateral VUR, primary or secondary reflux, first or second injection, previous surgical procedure and duplicated systems were included. Patients with neurogenic bladder and/or untreated voiding dysfunction were excluded. Preoperative evaluation included VCUG, renal bladder ultrasound (RBUS) and DMSA scan when deemed necessary. A single skilled surgeon performed the double HIT technique with patients under general anesthesia. Follow-up included VCUG, RBUS 3 month postoperatively and RBUS 1 year postoperatively. A total of 69 refluxing renal units were treated. When using up to 2 injections, the overall cure rate, defined as grade 0 reflux, was 81.2%. A total of 6 refluxing renal units underwent a second injection. This cure rate differed according to the grade, ranging from 60% for grade V to 100% for grade I. One patient suffered from pyelonephritis 3 weeks after surgery and no patient had evidence of obstruction after a mean follow-up of 12 months. Results were interpreted as comparable to the outcomes of Dx/HA, but limitations were relatively short follow-up and absence of comparative group.

A second trial from the same group was published by Blais et al. in 2015\textsuperscript{34}. The aim of this study was to compare the efficacy of PAHG and Dx/HA in endoscopic treatment of VUR. For this purpose, a single center and single surgeon prospective non-randomized study was designed. Patients under 18 years of age with grade I to IV VUR confirmed by VCUG were included. Exclusion criteria were grade V VUR,
previous endoscopic treatment, active infection, untreated dysfunctional elimination syndrome, neurogenic bladder and history of bladder extrophy. The choice of the agent was based on product availability and alternate use of the two bulking agents was promoted. A total of 45 patients were included in each group, 78 refluxing renal units in the PAHG group and 71 in the Dx/HA group. The overall success rate after the first injection was 73.1% with PAHG and 77.5% with Dx/HA (p = 0.54) at the 3-month VCUG. One patient in each group suffered from febrile UTI after surgery. In the Dx/HA group, 2 patients developed symptomatic ureteral obstruction and one needed temporary ureteral stenting.

The last trial from the same institution was published by Ramsay et al. in 2017 and evaluated the long-term results and safety of PAHG in endoscopic treatment of VUR. A prospective single-surgeon study was designed to evaluate PAHG in endoscopic treatment of grade I to V VUR. Patients were included in this trial after exiting previous studies. All children had a VCUG and RBUS prior to surgery. DMSA scan was performed only when it was considered necessary. The same double-HIT technique was performed. Follow-up included VCUG and RBUS at 3 months, followed by RBUS at 12 and 36 months. To avoid unnecessary radiation and invasive manipulation, VCUG was not systematically repeated at one and three years. Success was defined by the absence of both VUR and de novo or worsening hydronephrosis. Authors looked at the complications to assess the safety of the procedure, such as calcification of the injected agent and febrile UTIs. A total of 76 patients (53 females, 23 males) with a median age of 45 months were included. The median volume of PAHG injected per refluxing renal unit was 1.0 ml, with volumes ranging from 0.6 to 2.5 ml. Overall success rates at 3 months were 70.7% for grades I to V and 72.6% when excluding grade V. Success rates were higher for patients with a duplicated renal system (87.5%), history of renal reimplantation (100%) and history of previous injection with another agent (80%).

Only 2 patients experienced febrile UTI and only one had persistent VUR at the 3-month VCUG. At the 36-month RBUS follow-up, no patient had developed de novo or worsening hydronephrosis or calcification of the bulking agent and no case of ureteral obstruction were reported.

The only trial from a different group regarding the use of PAHG for endoscopic injection of VUR would be valuable. Moreover, additional studies are needed to evaluate the use of PAHG for endoscopic injection of VUR would be valuable. Moreover, additional studies are needed to evaluate the use of PAHG for endoscopic injection of VUR. The contribution of PAHG is therefore an attractive alternative bulking agent for VUR treatment. The contribution of other centers to evaluate the use of PAHG for endoscopic injection of VUR would be valuable.

Conclusion

Vesicoureteral reflux is a major concern in pediatric urology and management aim to prevent consequences without creating new comorbidities. Efforts have been made to find minimal invasive treatments and endoscopic injection of bulking agent is one of them. Among all agents studied, dextranomer hyaluronic acid remains the most popular. Polyacrylamide hydrogel has been studied as an alternative bulking agent and showed comparable results at 3 years follow-up. Furthermore, no ureteral obstruction and no calcification of injected PAHG were observed. These complications are two major concerns for pediatric urologists. PAHG is therefore an attractive alternative bulking agent for VUR treatment. The contribution of other centers to evaluate the use of PAHG for endoscopic injection of VUR would be valuable. Moreover, additional studies are needed to evaluate the longer-term efficacy and safety of PAHG in VUR.
