Previous studies have shown that the impurity Li$_3$V$_2$(PO$_4$)$_3$ in LiVPO$_4$F will adversely affect its electrochemical performance. In this work, we show that the crystalline composition of LiVPO$_4$/F/C is mainly influenced by the environmental temperature. The content of Li$_3$V$_2$(PO$_4$)$_3$ formed in LiVPO$_4$/F/C is 0, 11.84 and 18.75% at environmental temperatures of 10, 20, and 30°C, respectively. For the sample LVPF-30C, the SEM pattern shows a kind of alveolate microstructure and the result of selected area electron diffraction shows two sets of patterns. The LiVPO$_4$/F/C cathode without impurity phase Li$_3$V$_2$(PO$_4$)$_3$ was prepared at 10°C. The selected area electron diffraction result proves that the lattice pattern of LiVPO$_4$F is a regular parallelogram. Electrochemical tests show that only one flat plateau around 4.2 V appears in the charge/discharge curve, and the reversible capacity is 140.4 mAh·g$^{-1}$ at 0.1 C, and 116.3 mAh·g$^{-1}$ at 5 C. From these analyses, it is reasonable to speculate that synthesizing LiVPO$_4$/F/C at a low environmental temperature is a practical strategy to obtain pure crystalline phase and good electrochemical performance.

Keywords: lithium-ion batteries, lithium vanadium fluorophosphates, environmental temperature, alveolate structure, electrochemical performance

INTRODUCTION

The rechargeable lithium-ion battery has been widely studied because of its applications in electric vehicles, mobile phones, and energy storage devices (Huang et al., 2009; Konarov et al., 2017). LiFePO$_4$ delivers superior thermal stability and excellent cyclic performance, but a low working potential decreases its energy density (Yamada et al., 2003; Kim et al., 2015; Eftekhari, 2017; Wu et al., 2017). A novel cathode lithium vanadium fluorophosphate (LiVPO$_4$F) material has been reported (Gover et al., 2006). The working potential (4.2 V) of LiVPO$_4$F is much higher than that of LiFePO$_4$ and LiCoO$_2$ (Ma et al., 2013a; Hu et al., 2014; Wu et al., 2016). Moreover, the thermal stability of LiVPO$_4$F is better than that of LiFePO$_4$ and LiCoO$_2$ (Wang et al., 2014; Xu et al., 2015). If the shortcoming of electronic conductivity is solved, LiVPO$_4$F will be an outstanding cathode material (Reddy et al., 2010; Ma et al., 2013b; Satish et al., 2016). Some improvements have been adjusted to LiVPO$_4$F cathode, such as cation doped, carbon coated and various synthesized routes (Wang et al., 2013a; Liu et al., 2016; Wu et al., 2017). Recently, adopting
facile and controllable methods to prepare LiVPO$_4$F is the key area of research. LiVPO$_4$F was reported by two-step carbothermal reduction in some references. However, this method suffers from high energy consumption and a large content of carbon, because the intermediate VPO$_4$ is prepared separately at 700–800°C (Ma et al., 2014; Liu et al., 2015; Wang et al., 2016). Therefore, the formation of impurity Li$_3$V$_2$(PO$_4$)$_3$ is directly related to the environmental temperature. The formation mechanism was investigated through further analysis of the structure and synthesis procedures.

**EXPERIMENTAL**

**Materials Synthesis**

LiVPO$_4$/C was synthesized by using a novel chemical reduction method. The chemical reactant used was of analytical reagent grade. 0.03 mol H$_2$C$_2$O$_4$ dissolved in deionized water was used as a chelating agent and reducing agent. 0.01 mol V$_2$O$_5$ was added slowly under vigorous magnetic stirring at 60°C. LiF and NH$_4$H$_2$PO$_4$ at the molar ratio of 1:1 to vanadium were introduced in after 10 min. A PVDF carbon source of 1.4943 g was dispersed in 30 ml water in a solution of hexadecyl trimethyl ammonium bromide under ultrasonic assistance at 50°C. Subsequently, the PVDF suspension was added to the reaction system. Finally, the suspension was dried overnight in vacuum at 85°C. The precursor was presintered at 400°C for 5 h and sintered at 800°C for 4 h in a tubular furnace with flowing high-purity argon.

**Characterization**

The crystal structure of the material was examined by X-ray diffraction (XRD, Rigaku D/MAX 2500). The morphology and elemental content were investigated with scanning electron microscopy (SEM, Navo NanoSEM230) and energy dispersive spectroscopy (EDS). Nanoscale morphology and selected area electron diffraction (SAED) were performed by using high-resolution transmission electron microscopy (HRTEM, JEOL-3010).

**Electrochemical Test**

The electrochemical performance of LiVPO$_4$/F/C electrodes was evaluated using an Arbin BT2000 battery test system. The cathode film was fabricated by mixing LiVPO$_4$/F/C (80 wt.%), acetylene black (15 wt.%), and PVDF (5 wt.%) in the solvent N-methyl pyrrolidone, and the slurry was coated on an aluminum collector. The electrodes were dried in a vacuum oven at 120°C for 12 h and 2016 coin-type cells were assembled in a glove box (S1220/750). The electrolyte was 1.3 mol·L$^{-1}$ LiPF$_6$ in a mixing solvent of ethylene carbonate, dimethyl carbonate, and ethyl methyl carbonate (1:1:1). A lithium foil and a polypropylene separator (Celgard 2400) were used as counter electrode and separator, respectively.

**RESULTS AND DISCUSSION**

The electrochemical performance of triclinic LiVPO$_4$/F/C is partially determined by the content of impurity Li$_3$V$_2$(PO$_4$)$_3$/C in it. Our study revealed that LiVPO$_4$/F prepared at a high environmental temperature delivers poor performance. To investigate the reason for this, we synthesized LiVPO$_4$/F/C at different environmental temperatures (30, 20, and 10°C), and named the respective samples as LVPF-30C, LVPF-20C, and LVPF-10C.

The XRD patterns of the samples are shown in Figure 1A. The main diffraction peaks correspond to a triclinic system with the space group of P-1, and can be indexed as the standard pattern of LiVPO$_4$/F (Barker et al., 2003; Huang et al., 2009). The absence of peaks corresponding to crystalline carbon proves that carbon is amorphous. No impurity peaks in LVPF-10C, which delivers the strongest peaks among the samples, was found. The refined cell parameters a, b, and c were 5.174, 5.308, and 7.509 Å, and the cell volume was 174.18 Å$^3$. These results compare well with the classic results reported by Barker (Barker et al., 2005). However, the peaks at 20.69°, 23.53°, and 24.48° belonging to the impurity Li$_3$V$_2$(PO$_4$)$_3$ (symbol # in Figure 1A) occur in the curves of LVPF-30C and LVPF-20C (Zhu et al., 2008). The percentages of Li$_3$V$_2$(PO$_4$)$_3$ in LiVPO$_4$/F were estimated by refining the XRD patterns in Figure 1B. The content of Li$_3$V$_2$(PO$_4$)$_3$ increased gradually from 0% (10°C) to 11.84% (20°C) and 18.75% (30°C). Hence, our preliminary presumption is that low environmental temperature plays an important role in the preparation of pure LiVPO$_4$/F.

In Figure 1C, four flat plateaus (A, B, C, and D) appear in the discharge curves of LVPF-30C. The predominant plateau A around 4.2 V is attributed to LiVPO$_4$/F/C, and is in accordance with Barker’s work (Barker et al., 2003), and B, C, and D are assigned to Li$_3$V$_2$(PO$_4$)$_3$/C. The specific capacities at 0.1 C and 5 C are 138.6 and 101.6 mAh·g$^{-1}$. However, when temperature drops to 20°C (corresponding to LVPF-20C, Figure 1D), the plateaus of Li$_3$V$_2$(PO$_4$)$_3$/C are shorter than before, establishing the decreasing content of impurity. The specific capacity increases obviously, especially at 5 C (118.3 mAh·g$^{-1}$). Further, only a plateau A at 4.2 V without other plateaus of impurity Li$_3$V$_2$(PO$_4$)$_3$/C is observed even though we use a synthesis method that employs a novel chemical reduction route. The content of Li$_3$V$_2$(PO$_4$)$_3$ should be carefully controlled because it may adversely affect the performance of the LiVPO$_4$/F cathode.

Hence, our preliminary presumption is that low environmental temperature plays an important role in the preparation of pure LiVPO$_4$/F.
impurity Li$_3$V$_2$(PO$_4$)$_3$/C possesses the optimum capacity at a high current density. The reason is that Li$_3$V$_2$(PO$_4$)$_3$/C is a fast ion conductor and allows a fast transfer of lithium ions in the cathode. Nevertheless, an excess of the impurity Li$_3$V$_2$(PO$_4$)$_3$/C in LiVPO$_4$/F/C adversely affects the rate and the cycling capability.

In Figure 2A, the alveolate structure can be easily observed in LVPF-30C. The surface of most particles is broken. This structure is observed in the HRTEM image. The SAED pattern is made up of two sets of lattices with different characteristics (inset of Figure 2B). These parallelogram lattices are attributed to triclinic LiVPO$_4$F (bottom) and monoclinic Li$_3$V$_2$(PO$_4$)$_3$ (top). In Figure 2C, the EDS image in the alveolate field proves the existence of Li$_3$V$_2$(PO$_4$)$_3$ distinctly because the content of fluorine is much lower than that of vanadium. Figures 2D,E show that vanadium is uniformly distributed on the surface of particles and a small quantity of fluorine is detected. This proves that impurity Li$_3$V$_2$(PO$_4$)$_3$ without fluorine is formed in the alveolate zone.

There is no alveolate structure on the flawless surface of LVPF-10C (Figure 2F) and the lattice fringes can be clearly observed (Figure 2G). The pattern of SAED in the square frame is a typical parallelogram, and is similar to the bottom lattice in Figure 2B. This pattern is attributed to the typical crystalline form of LiVPO$_4$F with the triclinic system. Thus, LVPF-10C possesses a good crystalline morphology with a thin layer covering on the surface of the crystalline LiVPO$_4$F. Its lattice pattern is a series
of concentric circles, which is the characteristic of amorphous carbon (Song et al., 2008). The atomic contents of vanadium and fluorine are 8.61 and 8.30%, respectively, and match well with the atomic ratio of LiVPO$_4$F in Figure 2H. Thus, we conclude that low temperature ($10^\circ$C) helps to prepare pure phase LiVPO$_4$F.

The formation mechanism of the alveolate structure is investigated in Figure 3. On one hand, the excessive oxalic acid hydrolyzes in deionized water and produces hydrogen ions in aqueous solution. Ammonium dihydrogen phosphate generates ammonium ions in the hydrolysis reaction. A fluoride compound is formed when a hydrogen ion and an ammonium ion are combined with a fluoride ion released by LiF. Therefore, HF and NH$_4$F are formed in the reaction (Zhou et al., 2009). It is well known that fluoride compounds are unstable and easily evaporate. From the viewpoint of reaction kinetics, the volatilization rate of fluoride will increase at least 6 to 8 times.
at 30°C compared to 10°C in reaction and drying. Therefore, the content of fluorine in the precursor at 30°C is evidently lower than that at 10°C. It can be inferred that the impurity Li$_2$V$_2$(PO$_4$)$_3$ is formed in this condition. On the other hand, the temperature of the tubular furnace drops slowly at 30°C. The cooling rate of LVPF-30C is lower than that of LVPF-10C. The longer cooling time of LVPF-30C accelerates the evaporation of fluoride, especially at 600–800°C. Therefore, this ensures that the fluorine content in LVPF-30C is much less than the value determined. The impurity Li$_2$V$_2$(PO$_4$)$_3$ is formed, which is in accordance with the above analysis of its structure and morphology.

Hence, the volatilization of fluoride should be inhibited in the preparation processes of LiVPO$_4$F. Based on all of the evidence we have presented above, we legitimately conclude that a lower environmental temperature is more helpful to synthesize a LiVPO$_4$F/C cathode with a low content of impurity and excellent electrochemical performance.

**CONCLUSIONS**

A sample of LVPF-10C, which was prepared at an environmental temperature of 10°C, exhibited a regular parallelogram space pattern that is attributed to the pure triclinic form of LiVPO$_4$F. High environmental temperature accelerates the volatilization of fluoride in the drying and sintering process and decreases the fluorine content. Then, a large quantity of Li$_2$V$_2$(PO$_4$)$_3$ reduces the plateaus in the discharge curves and deteriorates the rate of performance in LVPF-30C. Therefore, our work is devoted to give a direction to improve the synthetic process and advise what we need to do in the future.
