Abstract
We present a method to compute dispersive shock wave solutions of the Korteweg–de Vries equation that emerge from initial data with step-like boundary conditions at infinity. We derive two different Riemann–Hilbert problems associated with the inverse scattering transform for the classical Schrödinger operator with possibly discontinuous, step-like potentials and develop relevant theory to ensure unique solvability of these problems. We then numerically implement the Deift–Zhou method of nonlinear steepest descent to compute the solution of the Cauchy problem for small times and in two asymptotic regions. Our method applies to continuous and discontinuous initial data.

Keywords: inverse scattering, step-like data, Riemann–Hilbert problems, dispersive shock waves

1. Introduction
Consider the Korteweg–de Vries (KdV) equation in the form

\[ u_t + 6uu_x + u_{xxx} = 0, \quad x \in \mathbb{R}, \]  

which is completely integrable [12] and admits soliton solutions that decay exponentially fast as \( x \to \pm \infty \). For initial initial data with sufficient smoothness and decay on a zero background, the solution of the Cauchy initial-value problem is given asymptotically by a sum of
1-solitons in the (soliton) region $x/t > C$ for some constant $C > 0$ as $t \to +\infty$ [15]. Presence of non-zero boundary conditions at infinity, however, gives rise to a fundamentally different long-time solution profile. Monotone initial data $u(x, 0) = q(x)$ with boundary conditions

$$\lim_{x \to -\infty} q(x) = q_1 \quad \text{and} \quad \lim_{x \to +\infty} q(x) = q_r,$$

(2)
gives rise to generation of a number of dispersive shock waves (DSWs) if $q_1 > q_r$ [16]. If $q_1 < q_r$, however, the dynamics generate a rarefaction fan and the solution is asymptotically given by $(x - x_0)/(6t)$ for $q_1t < x - x_0 < q_r t$ as $t \to +\infty$ [2]. An asymptotic description for the solution is much more complicated in the former case, where DSWs emerge [9].

The generation of DSWs is also closely related to the regularization of shock waves in Burgers’ equation $u_t + uu_x = 0$ using the small-dispersion KdV (sKdV) equation $u_t + 6uu_x + \varepsilon^2 u_{xxx} = 0$, $x \in \mathbb{R}$, $0 < \varepsilon \ll 1$. The initial-value problem for the sKdV equation with so-called ‘single hump’ initial data was considered in the seminal work of Lax and Levermore [22] and the subsequent series of papers [23–25] where inverse scattering transform methods were used to obtain the limiting solution as $\varepsilon \downarrow 0$ for fixed $t > 0$. The methodology of Lax–Levermore was then extended by Venakides [41] to ‘single potential-well’ initial data where the reflection coefficient plays a significant role as $\varepsilon \downarrow 0$. Formation of DSWs, relevant asymptotics and the relation to the boundary conditions (2) in this small dispersion limit $\varepsilon \downarrow 0$ of the sKdV equation were studied numerically in the works of Grava and Klein [13, 14]. Recently, the generation of DSWs have been studied in various physical contexts, such as viscous fluid conduits [26]. A pseudospectral numerical method was developed by Fornberg and Whitham to study the solutions of (1) with initial step and well profiles in [11]. Long-time asymptotic behavior of solutions for (1) with step-like initial data satisfying $q_1 > q_r$ (the case where a DSW is generated) in a region near the wave front was investigated by Hruslov in [18]. Recently, Rybkin presented an inverse scattering theory to solve the initial value problem with bounded initial data that decays rapidly to 0 as $x \to +\infty$ but unrestricted otherwise [33]. For a review on DSWs, see [3] and the articles in this special issue (in particular, see [4, 10, 27, 34, 36]).

We consider solutions of (1) from computational special functions point of view. Owing to the integrability of the KdV equation, solutions of (1) have representations in the form of Riemann–Hilbert problems (from the associated inverse scattering transform) that can be phrased as small-norm singular integral equations in various asymptotic regions for large values of $x$ or $t$ with the aid of the Deift–Zhou method of nonlinear steepest descent. When implemented numerically this framework leads to a robust numerical method for computing solutions for all values of $x$ and $t$ [32]. This is in analogy with classical special functions, e.g. the Airy function, where many software packages are available for robust computations with arbitrarily large values of parameters. Solutions of the KdV equation should therefore be computable with the same robustness that, Airy functions, for example, are computable. This framework also allows one the freedom of performing nonlinear superpositions that are otherwise beyond reach [37, 38]. Specifically, we consider the solution of the KdV equation with Heaviside initial data, as displayed in figure 1, to be a special function. Taking a more ambitious stance, we aim to compute solutions of (1) with (2) for all $x$ and $t$. This paper is the first step in that direction. We anticipate that this full development will allow the investigation and classification of new and well-known phenomena within the KdV equation such as identifying the spectral signature of a DSW.

Unlike classical time-stepping methods, the numerical inverse scattering approach requires no spatial discretization, no integration in time and no domain approximation (i.e. approximating the solution on $\mathbb{R}$ with a solution on a large interval). The only two sources of error
are (1) error in computing the scattering data and (2) error in solving the inverse problem (i.e.,
error in computing the solution of a Riemann–Hilbert problem). We point out that (1) is effec-
tively present in time-stepping routines when the initial data is approximated in some basis.
The error (2) can be seen to be the counterpart of integration error but unlike classical meth-
ods, the 'integration' error does not increase in time. This can be seen to be a consequence of
the ability to analyze the Riemann–Hilbert problem asymptotically [32].

More precisely, we consider solutions of the KdV equation (1) with step-like asymptotic profile
\[ |u(x,t) - H_c(x)| = o(1), \quad |x| \to \infty, \]  
for all \( t \in \mathbb{R}_{\geq 0} \), where
\[ H_c(x) := \begin{cases} 
-c^2 & x > 0, \\
0 & x \leq 0,
\end{cases} \]
for \( c \in \mathbb{R}_{>0} \). To specify the initial data for the KdV equation, we write
\[ u(x,0) = u_0(x) + H_c(x) \]
and \( u_0 \) is a real-valued function. Our theoretical developments require \( u_0 \), which we refer to
as a perturbation, to be in a polynomially-weighted \( L^1 \) space while our computational results
require more: \( u_0 \) should be at least piecewise smooth and in an exponentially-weighted \( L^1 \)
space. We develop the relevant Riemann–Hilbert (RH) theory for the inverse scattering trans-
form (IST) associated with the KdV equation (i.e. for the classical Schrödinger operator with
step-like potentials \( u(\cdot, t) \)) and pose two different RH problems that are amenable to numerical
computations using the framework introduced in [39]. We then make use of this RH theory
to compute the solution of the Cauchy initial-value problem for the KdV equation with the
boundary conditions (3) for small \( t \geq 0 \). Figure 1 gives the solution of the KdV equation with
\( u_0(x) = 0, \quad c = \sqrt{2} \) at \( t = 1 \).

Remark 1.1. Let \( \tilde{u} \) solve (1) with
\[ \tilde{u}(x,0) = u(x,0) - a, \]
then
$$u(x,t) = \tilde{u}(x - 6at, t) + a.$$  \hspace{1cm} (7)

This is the so-called Galilean boost symmetry of the KdV equation. Using this, any solution \( \tilde{u} \) of (1) satisfying (2) with \( q_l \geq q_r \) can be obtained from a solution \( u \) satisfying (3) by
$$\tilde{u}(x,t) = u(x - 6q_lt, t) + q_l. \hspace{1cm} c^2 = q_l - q_r.$$  \hspace{1cm} (8)

1.1. Outline of the paper

In section 2, we present the necessary scattering theory for Schrödinger operators with step-like potentials in context of the direct scattering transform for the KdV equation (1). Some of this material is based on the work of Kappeler and Cohen [6, 19], and also on the work of Deift and Trubowitz [8]. As smoothness and decay properties of various spectral functions are important in obtaining a robust numerical inverse scattering transform, we include the details on scattering theory as they become necessary. In section 3, we define the right and left reflection coefficients on \( \mathbb{R} \), derive their decay and smoothness properties as well as relations between left and right scattering data. We then pose two RH problem formulations of the inverse scattering transform for the KdV equation, one using the left scattering data and another using the right scattering data. We note that one needs to use both of these problems to have an asymptotically accurate computational method. This discussion unifies the work in [9] with that of Cohen and Kappeler.

In section 4, we give integrability conditions on the perturbation \( u_0 \) necessary for the deformations of the RH problems to be made in the subsequent sections and give details on computation of the scattering data. In section 5 we introduce contour deformations (analytic transformations) of RH problems 3 and 4 to apply the Deift–Zhou method of nonlinear steepest descent and compute the inverse scattering transform associated with the KdV equation for all \( x \in \mathbb{R} \) at \( t = 0 \). Having done that, we extend these deformations to small \( t > 0 \) in section 6 to compute the solution \( u(x,t) \) of the Cauchy problem for the KdV equation in two asymptotic regions of the \((x,t)\)-plane. In section 7 we present the computed solutions \( u(x,t) \) for various step-like initial data and present comparison with solutions obtained via time-stepping.

The inclusion of solitons (if any) by incorporating residue conditions in these RH problems and derivation of the time dependence for the scattering data is performed in appendix A. We prove theorems on the unique solvability of these RH problems in appendix B. We apply the dressing method [42] to establish a posteriori that the RH problems we pose produce solutions of the KdV equation, see theorem 3.16. Establishing unique solvability of the RH problems, without assuming existence of the solution of the KdV equation, is necessary to apply the dressing method. Additionally, in the process, we show that a singular integral operator that we encounter in the numerical solution of a RH problem is invertible. For these reasons we expend considerable effort in appendix B.

Remark 1.2. We consider the setting \( q_l > q_r \). The case \( q_l < q_r \) can be treated by mapping \((x,t) \mapsto (-x,-t)\) as this leaves (1) invariant, noting that theorem 3.16 applies.

Notation. We use the following notational conventions:

- We denote the following weighted \( L^p \) spaces on an oriented (rectifiable) contour \( \Gamma \):
$$\begin{align*}
L^p(\Gamma, \, d\mu) &= \left\{ f: \Gamma \to \mathbb{C} \mid \int_\Gamma |f(s)|^p \, d\mu(s) < \infty \right\}.
\end{align*}$$ \hspace{1cm} (9)

Also, $L^p(\Gamma) := L^p(\Gamma, |ds|)$ where $|ds|$ refers to arclength measure.

- We use $\sigma_1$ to denote the first Pauli matrix
  
  $\sigma_1 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$.  

- In the discussion of RH problems we use the following notation. For a function $f$ defined on a subset of $\mathbb{C}$ with a non-empty interior, we will use $f(z)$ to refer to the values of $f$. For a function $f$ defined on a contour $\Gamma \subset \mathbb{C}$ we will use $f(s)$ to refer to values of $f$.

- Given a point $s$ on an oriented contour $\Gamma \subset \mathbb{C}$, $f^+(s)$ (resp. $f^-(s)$) denote the non-tangential boundary values of $f(z)$ as $z \to s$ from left (resp. right) with respect to orientation of $\Gamma$.

- We use bold typeface to denote matrices and vectors with the exception of $\sigma_1$ defined in (10).

2. The scattering problem and its solution

The spatial part of the Lax pair for the KdV equation is the spectral problem

$$L \psi = E \psi, \quad L \psi := -\psi_{xx} - u(x,t) \psi, \quad E = z^2,$$

where $u$ satisfies the KdV equation (1) and $L$ is the Schrödinger operator. The temporal part of the Lax pair is the evolution equation

$$\psi_t = P \psi, \quad P \psi := -4\psi_{xxx} - 3u(x,t)\psi - 6u(x,t)\psi_x.$$

To compute scattering data associated with the given Cauchy initial data we proceed with the construction of the Jost solutions of the spectral problem (11). We first solve the scattering problem at $t = 0$. It is convenient to define the complementary functions $u^{l/r}_0(x)$ by

$$u^l_0(x) = \begin{cases} u_0(x) & x \leq 0, \\ u_0(x) - c^2 & x > 0, \end{cases} \quad \text{and} \quad u^r_0(x) = \begin{cases} u_0(x) & x \geq 0, \\ u_0(x) + c^2 & x < 0. \end{cases}$$

Recall that we assume that the Cauchy initial data is

$$u(x,0) = u^l_0(x).$$

2.1. Asymptotic spectral problem as $x \to -\infty$

On the left-end of the spatial domain, formally, (11) is asymptotically

$$\psi_{xx} = -z^2 \psi,$$

which has a fundamental set of solutions given by $\{ e^{icx}, e^{-icx} \}$. Therefore, for $z \in \mathbb{R}$, (11) has the following two independent solutions that are uniquely determined by their asymptotic behavior as $x \to -\infty$:

$$\phi^l(z,x) = e^{icx}(1 + o(1)), \quad x \to -\infty,$$

$$\phi^m(z,x) = e^{-icx}(1 + o(1)), \quad x \to -\infty.$$
These functions can be defined through Volterra integral equations
\[
\phi^p(z; x) = e^{i\lambda x} + \frac{1}{2i\xi} \int_{-\infty}^{x} \left( e^{i\xi(x-\xi)} - e^{i\xi(x-\xi)} \right) u_0(\xi) \phi^p(z; \xi) \, d\xi,
\]
\[
\phi^m(z; x) = e^{-i\lambda x} - \frac{1}{2i\xi} \int_{-\infty}^{x} \left( e^{i\xi(x-\xi)} - e^{i\xi(x-\xi)} \right) u_0(\xi) \phi^m(z; \xi) \, d\xi,
\]
which can be solved by Neumann series for \( z \in \mathbb{R} \) and \( u_0 \in L^1(\mathbb{R}, (1 + |x|) \, dx) \). See [6, chapter 1] and also [8, section 2] for a detailed construction.

### 2.2. Asymptotic spectral problem as \( x \to +\infty \)

Since \( u(x) \to -c^2 \) as \( x \to +\infty \), we consider, formally, the problem (11) asymptotically:
\[
\psi_{xx} - c^2 \psi = -c^2 \psi,
\]
and the eigenvalues associated with this differential equation are doubly-branched. More precisely, we have the fundamental set of bounded solutions to (19) given by \( \{ e^{i\lambda x}, e^{-i\lambda x} \} \), where \( \lambda \) depends on \( z \) through the algebraic relation \( \lambda^2 = z^2 - c^2 \) (characteristic equation for the eigenvalues \( \lambda \) of the constant coefficient equation (19)) which defines a Riemann surface with genus 0. To be concrete, we define \( \lambda(z) \) to be the function analytic for complex \( z \) with the exception of a horizontal branch cut
\[
\Sigma_c := [-c, c] \subset \mathbb{R},
\]
between the branch points \( z = \pm c \), whose square coincides with \( z^2 - c^2 \) and satisfies \( \lambda(z) = z + O(z^{-1}) \) as \( z \to \infty \). With these properties, \( \lambda(z) \) is a scalar single-valued complex function that is analytic in the region \( \mathbb{C} \setminus \Sigma_c \).

We now define two more independent solutions of the problem (11) that are determined, for \( \lambda(z) \in \mathbb{R} \) (i.e. \( z \in \mathbb{R} \setminus \Sigma_c \)), by their asymptotic behavior as \( x \to +\infty \):
\[
\psi^p(z; x) = e^{i\lambda x}(1 + o(1)), \quad x \to +\infty,
\]
\[
\psi^m(z; x) = e^{-i\lambda x}(1 + o(1)), \quad x \to +\infty.
\]
The existence of such solutions is again established through Volterra integral equations
\[
\hat{\phi}^p(z; x) = e^{i\lambda x} + \frac{1}{2i\xi} \int_{-\infty}^{x} \left( e^{i\xi(x-\xi)} - e^{i\xi(x-\xi)} \right) u_0(\xi) \hat{\phi}^p(z; \xi) \, d\xi,
\]
\[
\hat{\phi}^m(z; x) = e^{-i\lambda x} - \frac{1}{2i\xi} \int_{-\infty}^{x} \left( e^{i\xi(x-\xi)} - e^{i\xi(x-\xi)} \right) u_0(\xi) \hat{\phi}^m(z; \xi) \, d\xi,
\]
with \( \psi^{p/m}(z; x) = \hat{\phi}^{p/m}(\lambda(z); x) \). Again, the solutions \( \hat{\phi}^{p/m}(z; x) \) are well-defined for \( z \in \mathbb{R} \), and hence \( \psi^{p/m}(z; x) \) are well-defined for \( \lambda(z) \in \mathbb{R} \) (i.e. for \( z \in \mathbb{R} \setminus \Sigma_c \)) and \( u_0 \in L^1((1 + |x|) \, dx) \). See again [6, chapter 1] and also [8, section 2] for details.

### 2.3. Left and right reflection coefficients

The left (resp. right) reflection coefficient \( R_l \) (resp. \( R_r \)) are defined through the scattering relations for \( z \in \mathbb{R} \setminus \Sigma_c \)
\[
\psi^p(z; x) = a(z)\psi^p(z; x) + b(z)\phi^m(z; x),
\]
\[
\phi^m(z; x) = B(z)\psi^p(z; x) + A(z)\phi^m(z; x).
\]
Remark 2.1. It is important to note that while \( \psi^{p/m} \) and \( \phi^{p/m} \) are each sets of two linearly independent solutions of the same differential equation for all \( x \in \mathbb{R} \), if \( x = 0 \), we can replace \( u_0^{l/r} \) with \( u_0 \) in the associated integral equations (18) and (23). Then the scattering theory is interpreted as the traditional scattering theory for the one-dimensional Schrödinger operator, where one set of eigenfunctions is modified via the \( z \mapsto \lambda(z) \) transformation.

The system (24) can be solved for \( a(z), b(z) \) and \( A(z), B(z) \) using Wronskians \( W(f,g) = fg' - gf' \). Doing so, we define for \( z \in \mathbb{R} \) and \( \lambda(z) \in \mathbb{R} \),

\[
R_1(z) := \frac{b(z)}{a(z)} = \frac{W(\psi^p(z), \psi^m(z))}{W(\psi^p(z), \phi^m(z))}, \tag{25}
\]

\[
R_1(z) := \frac{B(z)}{A(z)} = -\frac{W(\phi^m(z), \psi^m(z))}{W(\phi^m(z), \psi^p(z))}. \tag{26}
\]

These are the so-called left \( (R_1) \) and right \( (R_3) \) reflection coefficients. We note that \( W(\phi^p, \psi^m) = -2iz \) and \( W(\phi^p, \psi^m) = -2i\lambda(z) \). Other important formulæ are

\[
a(z) = \frac{W(\psi^p(z), \psi^m(z))}{W(\phi^p(z), \phi^m(z))}, \quad b(z) = \frac{W(\phi^p(z), \psi^m(z))}{W(\phi^p(z), \psi^m(z))}, \quad A(z) = \frac{W(\psi^m(z), \psi^m(z))}{W(\phi^m(z), \phi^m(z))}, \quad B(z) = \frac{W(\phi^m(z), \phi^m(z))}{W(\phi^p(z), \psi^m(z))}. \tag{27}
\]

Remark 2.2. Presence of the step-like boundary conditions rules out the existence of reflectionless solutions (e.g. pure solitons). Indeed, setting both reflection coefficients \( R_1(z) \) and \( R_3(z) \) equal to 0 enforces \( \lambda(z) = z \), which holds if and only if \( c = 0 \), resulting in a zero-background (vanishing boundary conditions at infinity). Additionally, \( u(x,t) = H_t(x) \) is not a stationary solution of (1).

2.4. Regions of analyticity

To analyze regions of the complex plane where the functions \( \psi^{p/m}(z; x), \phi^{p/m}(z; x) \) are analytic in the variable \( z \), we consider the Jost functions

\[
N^p(z; x) := \phi^p(z; x) e^{-ix}, \quad N^m(z; x) := \phi^m(z; x) e^{ix},
\]

\[
M^p(z; x) := \tilde{\phi}^p(z; x) e^{-ix}, \quad M^m(z; x) := \phi^m(z; x) e^{ix}, \tag{28}
\]

From (18) and (23) it immediately follows that the functions \( N^{p/m}(z; x) \) and \( M^{p/m}(z; x) \) satisfy the following Volterra integral equations for \( z \in \mathbb{R} \)

\[
N^p(z; x) = 1 + \frac{1}{2iz} \int_{-\infty}^{x} \left( 1 - e^{2iz(z-x)} \right) u_0^l(\xi) N^p(z; \xi) \, d\xi, \tag{29}
\]

\[
M^p(z; x) = \frac{1}{2iz} \int_{-\infty}^{x} \left( e^{2iz(z-x)} - 1 \right) u_0^r(\xi) M^p(z; \xi) \, d\xi.
\]
\[ N^m(z; x) = 1 - \frac{1}{2iz} \int_{-\infty}^{z} \left( 1 - e^{2iz(x - \xi)} \right) u_0'(\xi) N^m(z; \xi) \, d\xi, \quad (30) \]
\[ \dot{M}^P(z; x) = 1 + \frac{1}{2iz} \int_{x}^{\infty} \left( 1 - e^{2iz(x - \xi)} \right) u_0'(\xi) \dot{M}^P(z; \xi) \, d\xi, \quad (31) \]
\[ \dot{M}^m(z; x) = 1 - \frac{1}{2iz} \int_{x}^{\infty} \left( 1 - e^{2iz(x - \xi)} \right) u_0'(\xi) \dot{M}^m(z; \xi) \, d\xi. \quad (32) \]

For (29) and (30) \( x - \xi > 0 \) and \( x - \xi < 0 \) for (31) and (32). This immediately implies that (29) and (32) can be analytically continued for \( \text{Im} \, z < 0 \) while (30) and (31) can be analytically continued for \( \text{Im} \, z > 0 \). It also follows from the asymptotics of \( \lambda(z) \) that \( (\text{Im} \, z)(\text{Im} \, \lambda(z)) > 0 \) for \( z \notin \mathbb{R} \). We note that these considerations immediately imply that \( a(z) \) and \( A(z) \) are analytic for \( \text{Im} \, z > 0 \).

We now consider the large \( z \) asymptotics of the above solutions, \( N^P/m \) and \( \dot{M}^P/m \) assuming \( z \) is in the appropriate region of analyticity.

**Lemma 2.3.** If \( u_0 \in L^1(\mathbb{R}) \) then for fixed \( x \in \mathbb{R} \), \( N^P/m(z; x) = 1 + O(z^{-1}) \) and \( \dot{M}^P/m(z; x) = 1 + O(z^{-1}) \) as \( z \to \infty \).

**Proof.** We concentrate on one function, \( N^m \), as the proof is the same for all. For \( |z| > 1 \) consider the Volterra integral equation
\[ N^m(z; x) + \frac{1}{2iz} \int_{-\infty}^{x} \left( 1 - e^{2iz(x - \xi)} \right) u_0'(\xi) N^m(z; \xi) \, d\xi = 1, \quad (33) \]
which can be rewritten as \((\mathcal{I} + \mathcal{K}_z)N^m(z; \cdot) = 1\), where \( \mathcal{K}_z \) is the Volterra integral operator given as
\[ [\mathcal{K}_z f](z; x) := \frac{1}{2iz} \int_{-\infty}^{x} \left( 1 - e^{2iz(x - \xi)} \right) u_0'(\xi) f(z; \xi) \, d\xi. \quad (34) \]

We proceed by showing that the Neumann series for the inverse operator \((\mathcal{I} + \mathcal{K}_z)^{-1}\) converges in the operator norm on \( C^0((-(\infty, X]) \) for fixed \( X \in \mathbb{R} \). Standard estimates yield
\[
\|\mathcal{K}_z^n\|_{C^0((-(\infty, X])} \leq \frac{1}{n!} \int_{-\infty}^{X} \int_{-\infty}^{X} \int_{-\infty}^{X} \cdots \int_{-\infty}^{X} \prod_{j=1}^{n} |u_0'(s_j)| \, ds_1 \cdots ds_n = - \frac{1}{n!} \int_{-\infty}^{X} \int_{-\infty}^{X} \int_{-\infty}^{X} \cdots \int_{-\infty}^{X} \prod_{j=1}^{n} |u_0'(s_j)| \, ds_1 \cdots ds_n = - \frac{1}{n!} \prod_{j=1}^{n} |u_0'|_{L^1(\mathbb{R})} + c^2 |X|^n, \quad n \in \mathbb{Z}_{>0}. \quad (35)\]

This implies that \( \|\mathcal{I} + \mathcal{K}_z\|^{-1}_{C^0((-(\infty, X])} \leq e^{\|u_0\|_{L^1(\mathbb{R})} + c^2 |X|} \) for \( |z| > 1 \). Then directly estimating (33), we have that
\[
|N^m(z; x) - 1| \leq \frac{\|u_0\|_{L^1(\mathbb{R})} + c^2 |X|}{|z|} e^{\|u_0\|_{L^1(\mathbb{R})} + c^2 |X|}, \quad |z| > 1, \quad (36)\]
proving the result for \( N^m \). Note that for \( X < 0 \), we can omit the \( c^2 |X| \) term from these estimates. \( \square \)
Remark 2.4. The reason it is enough to assume \( u_0 \in L^1(\mathbb{R}) \) to prove lemma 2.3 is because \( z \) is away from zero. The additional decay assumption \( u_0 \in L^1(\mathbb{R}, (1 + |x|) \, dx) \) in construction of the Jost solutions is required to handle the case when \( z = 0 \), i.e. in general, for \( z \in \mathbb{R} \).

We now compute the coefficients of the terms that are proportional to \( z^{-1} \) in the large-\( z \) asymptotic series expansions of these functions.

Lemma 2.5. For fixed \( x \), as \( |z| \to \infty, \Im z > 0 \),
\[
2i \zeta (N^m(z; x) - 1) \to \int_{-\infty}^{x} u_0^1(\xi) \, d\xi, \\
2i \zeta (\hat{M}^m(z; x) - 1) \to \int_{x}^{\infty} u_0^1(\xi) \, d\xi.
\] (37)

For fixed \( x \), as \( |z| \to \infty, \Im z < 0 \),
\[
2i \zeta (NP(z; x) - 1) \to -\int_{-\infty}^{x} u_0^1(\xi) \, d\xi, \\
2i \zeta (\hat{M}^m(z; x) - 1) \to -\int_{x}^{\infty} u_0^1(\xi) \, d\xi.
\] (38)

Proof. We only prove this for \( N^m \). The proofs for other functions are similar. Consider, as \( |z| \to \infty, \Im z > 0 \),
\[
2i \zeta (N^m(z; x) - 1) = \int_{-\infty}^{x} \left(1 - e^{2i \zeta (x - \xi)}\right) u_0^0(\xi)(1 + O(z^{-1})) \, d\xi \\
= \int_{-\infty}^{x} \left(1 - e^{2i \zeta (x - \xi)}\right) u_0^0(\xi) \, d\xi + O(z^{-1}) \\
= \int_{-\infty}^{x} u_0^1(\xi) \, d\xi - \int_{-\infty}^{x} e^{2i \zeta (x - \xi)} u_0^0(\xi) \, d\xi + O(z^{-1}).
\] (39)

The claim follows if we show \( \int_{-\infty}^{x} e^{2i \zeta (x - \xi)} u_0^0(\xi) \, d\xi = o(1) \) as \( |z| \to \infty, \Im z > 0 \). Indeed, this is the case since setting \( y := \xi - x \) we have
\[
\int_{-\infty}^{0} e^{-2ixy} u_0^0(y + x) \, dy \to 0, \quad |z| \to \infty
\] (40)
by the Riemann–Lebesgue lemma. \( \square \)

It is important to note that from this lemma we obtain
\[
\lim_{|z| \to \infty, \Im z > 0} 2i \zeta (MP(z; x) - 1) = \lim_{|z| \to \infty, \Im z > 0} 2i \zeta \frac{z}{\lambda(z)} (\hat{M}P(\lambda(z); x) - 1) = \int_{x}^{\infty} u_0^0(\xi) \, d\xi, \\
\lim_{|z| \to \infty, \Im z < 0} 2i \zeta (M^m(z; x) - 1) = -\int_{x}^{\infty} u_0^0(\xi) \, d\xi.
\] (41)

Lemma 2.6. If \( u_0 \in L^1(\mathbb{R}) \), for \( \Im z > 0 \), \( a(z) = 1 + O(z^{-1}) \) as \( z \to \infty \). Furthermore
\[
\lim_{z \to \infty, \Im z > 0} 2i \zeta (a(z) - 1) = \int_{-\infty}^{\infty} u_0^0(\xi) \, d\xi.
\] (42)
\[ W(\psi^m(z; -), \psi^p(z; -)) = \frac{1}{2iz}, \] with
\[
\psi^m(z; x) = e^{-iz} N^m(z; x),
\]
\[
\frac{\partial}{\partial x} \psi^m(z; x) = e^{-iz} \frac{\partial}{\partial x} N^m(z; x) - iz e^{-iz} N^m(z; x),
\]
\[
\psi^p(z; x) = e^{i(\zeta(z))x} M^p(z; x),
\]
\[
\frac{\partial}{\partial x} \psi^p(z; x) = e^{i(\zeta(z))x} M^p(z; x) + i\lambda(z) e^{i(\zeta(z))x} M^p(z; x).
\]
We find, by evaluating at \( x = 0, \)
\[
a(z) = \frac{1}{2iz} \left( \psi^m(z; x) \frac{\partial}{\partial x} \psi^p(z; x) - \psi^p(z; x) \frac{\partial}{\partial x} \psi^m(z; x) \right)
\]
\[
= \left( \frac{z + \lambda(z)}{2iz} \right) N^m(z; 0) M^p(z; 0)
\]
\[
+ \frac{1}{2iz} \left( N^m(z; x) \frac{\partial}{\partial x} M^p(z; 0) - M^p(z; x) \frac{\partial}{\partial x} N^m(z; 0) \right).
\]
It then follows that \( \frac{\partial}{\partial x} N^m(0; 0) = O(z^{-1}) \) and \( \frac{\partial}{\partial x} M^p(0; 0) = O(z^{-1}) \) so that
\[
\lim_{|z| \to \infty} 2iz(a(z) - 1) = \int_{-\infty}^{\infty} u_0(\xi) \, d\xi.
\]

\[ \square \]

2.5. Differentiability with respect to \( z \) on \( \mathbb{R} \)

We now consider the conditions on \( u_0 \) under which \( \psi^p/m \) and \( \phi^{p/m} \) and their first order \( x \)-derivatives both evaluated at \( x = 0 \), are differentiable with respect to \( z \) for \( z \in \mathbb{R} \).

**Lemma 2.7.** Let \( k \) be a non-negative integer and suppose that \( u_0 \in L^1(\mathbb{R}, (1 + |x|)^{k+1} \, dx) \).

Then for each fixed \( x \in \mathbb{R} \)
\[
\psi^p/m(\cdot; x), \psi^p/m(\cdot; x), \phi^{p/m}(\cdot; x), \phi^{p/m}(\cdot; x) \in C^k(\mathbb{R}).
\]
Furthermore, for fixed \( x \), the \( \ell \)th derivative with respect to \( z \), \( \ell \leq k \), is continuous as a function of \( u_0 \in L^1(\mathbb{R}, (1 + |x|)^{\ell+1} \, dx) \) and \( z \in \mathbb{R} \).

**Proof.** We prove this only for \( \phi^{m}(z; x) \) as the proofs for the others are similar. And to prove this for \( \phi^{m}(z; x) \), it suffices to prove this for the renormalized function \( N^m(z; x) \). We begin with rewriting the Volterra integral equation (30) as
\[
N^m(z; x) = \int_{-\infty}^{\xi} K(z; x - \xi)u_0(\xi)N^m(z; \xi) \, d\xi = 1, \quad K(z; x) := \frac{1}{2iz} \left( e^{2izx} - 1 \right),
\]
which has the form \((I + K_z)[N^m(z; \cdot)] = 1\) with \( K_z \) denoting the Volterra integral operator.
\[ K_\varepsilon[f](x) := -\int_{-\infty}^{x} K(z; x - \xi)u_0(\xi) f(\xi) \, d\xi. \]  

(49)

For \( h \neq 0 \), the difference function \( N^m_h(z; x) := N^m(z + h; x) - N^m(z; x) \) satisfies the equation

\[
N^m_h(z; x) - \int_{-\infty}^{x} K(z; x - \xi)u_0(\xi)N^m_h(z; \xi) \, d\xi = \int_{-\infty}^{x} [K(z + h; x - \xi) - K(z; x - \xi)]u_0(\xi)N^m(z + h; \xi) \, d\xi.
\]

(50)

Because the operator \((I + K_\varepsilon)\) on the left-hand side is invertible on \( C^0((-\infty, X]) \), for any fixed \( X \in \mathbb{R} \), uniform continuity of \( N^m(z; x) \) in the spectral variable \( z \) follows if we show that the right-hand side tends uniformly to zero as \( h \to 0 \). We fix \( X \in \mathbb{R} \). The modulus of the expression on the right-hand side of (50) is bounded above by

\[
I(x) := \int_{-\infty}^{x} |K(z + h; x - \xi) - K(z; x - \xi)|u_0(\xi)N^m(z + h; \xi) \, d\xi, \quad x \in (-\infty, X),
\]

(51)

since \( z \in \mathbb{R} \). Thus, we will show that \( I(x) \to 0 \) as \( h \to 0 \). We write \( K(z; x) := \kappa(z)x \), with

\[
\kappa(s) := \begin{cases} \frac{e^{su_1}}{\pi} & s \in \mathbb{R} \setminus \{0\}, \\ 1 & s = 0, \end{cases}
\]

(52)

which is bounded and differentiable for \( s \in \mathbb{R} \), with all of its derivatives being also bounded for all \( s \in \mathbb{R} \). Now, since for any fixed \( x \), \( N^m(z; x) \) is bounded uniformly in \( z \in \mathbb{R} \) (see the proof of lemma 2.3) by, say, \( M > 0 \), we have

\[
I(x) \leq M \int_{-\infty}^{x} |\kappa((z + h)(x - \xi)) - \kappa(z(x - \xi))| \frac{|x - \xi|}{1 + |\xi|} u_0(\xi) |(1 + |\xi|)| \, d\xi, \quad x \in (-\infty, X).
\]

(53)

Now, let \( \varepsilon > 0 \). Because \( \kappa \) is a bounded function and \( u_0 \in L^1((1 + |x|) \, dx) \) there exists \( \ell = \ell(\varepsilon) \leq X \) such that

\[
M \int_{-\infty}^{\ell} |\kappa((z + h)(x - \xi)) - \kappa(z(x - \xi))| \frac{|x - \xi|}{1 + |\xi|} u_0(\xi) |(1 + |\xi|)| \, d\xi < \varepsilon
\]

(54)

for all \( x \leq X \). Therefore

\[
I(x) \leq \varepsilon + M \int_{\ell}^{x} |\kappa((z + h)(x - \xi)) - \kappa(z(x - \xi))||x - \xi|u_0(\xi) \, d\xi, \quad x \in (-\infty, X]
\]

(55)

since \( z \in \mathbb{R} \). On the other hand, by the fundamental theorem of calculus we have

\[
\kappa((z + h)(x - \xi)) - \kappa(z(x - \xi)) = (x - \xi) \int_{\xi}^{z+h} \kappa'(s(x - \xi)) \, ds,
\]

(56)

which tends to zero, uniformly for \( \xi \in [\ell, x] \) for any \( x \leq X \), as \( h \to 0 \) because \( \kappa' \) is bounded \((|\kappa'(s)| \leq 1 \) for all \( s \in \mathbb{R} \)). Since \( \varepsilon > 0 \) in (55) can be made arbitrarily small, this establishes
uniform continuity of $N^m(z; x)$ with respect to $z \in \mathbb{R}$.

To generalize this to existence and continuity of the $z$-derivatives of $N^m(z; x)$ for $z \in \mathbb{R}$, we first use boundedness of $\kappa$ and all of its derivatives on $\mathbb{R}$ and immediately obtain the estimate

$$|\partial^j_z \kappa(z; x)| \leq C|x|^{j+1}, \quad j = 0, 1, 2, \ldots$$  \hspace{1cm} (57)

We then use integral equation satisfied by the difference quotient $N^m_h(z; x) := N^m(z; x)/h$:

$$N^m_h(z; x) = \int_{-\infty}^{X} K(z; x - \xi)u^0(\xi)N^m(\xi; \tilde{z}) \, d\xi = \int_{-\infty}^{X} \frac{K(z + h; x - \xi) - K(z; x - \xi)}{h} u^0(\xi)N^m(z + h; \tilde{z}) \, d\xi. \hspace{1cm} (58)$$

If we can show that the right-hand side converges to

$$\int_{-\infty}^{X} \partial_z K(z; x - \xi)u^0(\xi)N^m(z; \tilde{z}) \, d\xi \hspace{1cm} (59)$$

in $C^0([-\infty, X])$, for fixed $X \in \mathbb{R}$, as $h \to 0$ then we have shown that $\partial_z N^m(z; x)$ exists, and is given by

$$\partial_z N^m(z; x) = (I + \kappa \partial_z)^{-1} \int_{-\infty}^{X} \partial_z K(z; x - \xi)u^0(\xi)N^m(z; \tilde{z}) \, d\xi. \hspace{1cm} (60)$$

To establish this, we proceed as before. Fix $X \in \mathbb{R}$, $x \leq X$, and consider the difference

$$\int_{-\infty}^{X} \partial_z K(z; x - \xi)u^0(\xi)N^m(z; \tilde{z}) \, d\xi - \int_{-\infty}^{X} \partial_z K(z; x - \xi)u^0(\xi)N^m(z; \tilde{z}) \, d\xi \hspace{1cm} (61)$$

whose modulus is bounded above by

$$I_1(x) := \int_{-\infty}^{X} \left| \frac{K(z + h; x - \xi) - K(z; x - \xi)}{h} - \partial_z K(z; x - \xi) \right| u^0(\xi)N^m(z + h; \tilde{z}) \, d\xi. \hspace{1cm} (62)$$

Using the bound

$$\frac{|K(z + h; x - \xi) - K(z; x - \xi)|}{|h|} \leq C|x - \xi|^2, \hspace{1cm} (63)$$

for $h \neq 0$ and the fact that $u_0 \in L^1((1 + |x|)^2 \, dx)$, for any $e > 0$ there exists $\ell = \ell(e) \leq X$ such that

$$\int_{-\infty}^{\ell} \left| \frac{K(z + h; x - \xi) - K(z; x - \xi)}{h} - \partial_z K(z; x - \xi) \right| u^0(\xi)N^m(z + h; \tilde{z}) \, d\xi < e \hspace{1cm} (64)$$

and hence

$$I_1(x) \leq e + \int_{\ell}^{X} \left| \frac{K(z + h; x - \xi) - K(z; x - \xi)}{h} - \partial_z K(z; x - \xi) \right| u^0(\xi)N^m(z + h; \tilde{z}) \, d\xi. \hspace{1cm} (65)$$

Multiplying and dividing by the factor $(1 + |\xi|)^2$ inside the integral, using $u_0 \in L^1((1 + |x|)^2 \, dx)$ and boundedness of $N^m(z; x)$ for $x \in \mathbb{R}$, it now remains to show that
\[
\lim_{h \to 0} \sup_{\xi \leq \zeta \leq x} \frac{1}{(1 + |\xi|)^2} \left| \frac{K(z + h; x - \zeta) - K(z; x - \zeta)}{h} - \partial_{\zeta}K(z; x - \zeta) \right| = 0.
\]

(66)

To this end, we set \( s = x - \zeta > 0 \), and observe that
\[
\frac{K(z + h; s) - K(z; s)}{h} - \partial_{\zeta}K(z; s) = s \left( \frac{\kappa((z + h)s) - \kappa(zs)}{h} - \kappa'(zs) \right)
\]
\[
= \frac{s^2}{h} \int_{\tau = 0}^{\tau = h} (\kappa'((\tau s)x) - \kappa'(zs)) \, d\tau,
\]

(67)

and since \( z \leq \tau \leq z + h \), by the mean value theorem \( \kappa'(\tau x) = \kappa'(zs) + \kappa''(\tau_0) (\tau s - zs) \) for some \( \tau_0 \in (zs, \tau s) \). Then, since \( \kappa'' \) is bounded on \( \mathbb{R} \), say, by \( L \in \mathbb{R} \), we have
\[
\left| \frac{s^2}{h} \int_{\tau = 0}^{\tau = h} (\kappa'((\tau s)x) - \kappa'(zs)) \, d\tau \right| = \left| \frac{s^3}{h} \int_{\tau = 0}^{\tau = h} \kappa''(\xi) (\tau - z) \, d\tau \right| \leq L \frac{|s|^3}{|h|} \int_{\tau = 0}^{\tau = h} |\tau - z| \, d\tau = \frac{L}{2} |s|^3 |h|.
\]

(68)

Therefore \( I_1(x) \to 0 \) as \( h \to 0 \), and we have indeed shown that the right-hand side of (58) converges in \( C^0((-\infty, X]) \), implying that \( \partial_{\zeta}N^m(z; x) \) exists and is given by (60). We also, then note that for fixed \( x \), (60) is continuous as a function of \( u_0 \in \mathcal{L}^1((1 + |x|)^2 \, dx) \) and \( z \in \mathbb{R} \) because \( K_z \), as an operator on \( C^0((-\infty, X]) \), is continuous as a function of these same variables, and (59), as an element of \( C^0((-\infty, X]) \) is then continuous as a function of \( u_0 \in \mathcal{L}^1((1 + |x|)^2 \, dx) \) and \( z \in \mathbb{R} \).

We then proceed as before, to show that \( \partial_{\zeta}N^m(z; x) \) is (uniformly) continuous and then show that \( \partial_{\zeta}^2N^m(z; x) \) exists and is uniformly continuous if \( L^1((1 + |x|)^2 \, dx) \). Higher derivatives follow, inductively, in a similar manner because all derivatives of \( \kappa \) with respect to \( s \) are bounded. \( \square \)

3. Two Riemann–Hilbert problems

In this section we assume that \( a(z) \neq 0 \) for \( z \in \mathbb{C}^\pm \) (hence there are no solitons in the solution of the Cauchy problem), and relax this assumption in the following sections. See the notational remark at the end of section 3.6 for the notational conventions.

We continue with some basic definitions for Riemann–Hilbert problems. The following sequence of definitions can essentially be found in [39].

Definition 3.1.

1. As a point of reference, we first define the classical Hardy spaces on the upper- and lower-half planes. The Hardy spaces \( H^2(\mathbb{C}^\pm) \) consists of analytic functions \( f : \mathbb{C}^\pm \to \mathbb{C} \) which satisfy the estimate
\[
\sup_{r \geq 0} \| f(\cdot + ir) \|_{L^2(\mathbb{R})} < \infty.
\]

(69)

2. \( \Gamma \subset \mathbb{C} \) is said to be an admissible contour if it is finite union of oriented, differentiable curves \( \Gamma = \Gamma_1 \cup \cdots \cup \Gamma_k \), called component contours, which intersect only at their endpoints and tend to straight lines at infinity, the connected components of \( \mathbb{C} \setminus \Gamma \) can
be grouped into two classes $C_+$ and $C_-$ such that for $\Omega_1, \Omega_2 \in C_\pm$ the arclength of $\partial \Omega_1 \cap \partial \Omega_2$ is zero, and $-\Gamma = \{-s : s \in \Gamma\} = \Gamma$ with a reversal of orientation.

(3) For a connected component $\Omega \subset C \setminus \Gamma$, the class $E^2(\Omega)$ is defined to be the set of all analytic functions $f$ in $\Omega$ such that there exists a sequence of curves $(\gamma_n)_{n \geq 1}$ in $\Omega$ satisfying

$$\sup_n \int_{\gamma_n} \frac{|ds|}{|s-a|^2} < \infty, \text{ for some } a \in C \setminus \Omega, \tag{70}$$

that tend to $\partial \Omega$ in the sense that $\gamma_n$ eventually surrounds every compact subset of $\Omega$ such that

$$\sup_n \int \gamma_n |f(s)|^2 |ds| < \infty. \tag{71}$$

(4) For an admissible contour $\Gamma$, define the Hardy space $H^\pm(\Gamma)$ to be the class of all analytic functions $f : C \setminus \Gamma \rightarrow C$ such that $f|_{\Omega} \in E^2(\Omega)$ for every connected component $\Omega$ of $C \setminus \Gamma$. This is a generalization of (1). We also use the notation $H^\pm(\Gamma)$ if just modification of the orientations of the component contours make $\Gamma$ admissible.

For $f \in L^2(\Gamma)$, define the Cauchy integral

$$C_\Gamma f(z) = \frac{1}{2\pi i} \int_{\Gamma} \frac{f(s)}{s-z} \, ds, \quad z \notin \Gamma. \tag{72}$$

We have the following standard facts.

(1) From standard theory (see, [39], for example) it follows that $C_\Gamma : L^2(\Gamma) \rightarrow H^\pm(\Gamma)$.

(2) Furthermore, the Cauchy operator $C_\Gamma$ maps $L^2(\mathbb{R})$ onto $H^\pm(\Gamma)$, and therefore every function $f \in H^\pm(\Gamma)$ has two $L^2(\Gamma)$ boundary values on $\Gamma$, one taken from $C_+$ and the other taken from $C_-$. We use $C^\pm_\Gamma f(s)$ to denote these boundary values, and note the identity that $C^+_\Gamma f(s) - C^-_\Gamma f(s) = f(s)$ for a.e. $s \in \Gamma$.

(3) The last fact we need is that $C^\pm_\Gamma$ are bounded operators on $L^2(\Gamma)$ if $\Gamma$ is admissible$^3$.

**Definition 3.2.** An $L^2$ solution $N$ to an RH problem on an admissible contour $\Gamma$

$$N^+(s) = N^-(s)J(s), \quad s \in \Gamma, \quad N(z) = [1 \quad 1] + O(z^{-1}), \tag{73}$$

is a solution $N(\cdot) - [1 \quad 1] \in H^\pm(\Gamma)$ such that $N^+(s) = N^-(s)J(s)$ is satisfied for a.e. $s \in \Gamma$.

Note that an $L^2$ solution does not necessarily satisfy the uniform $O(z^{-1})$ condition at infinity.

### 3.1. Left Riemann–Hilbert problem

We use the scattering relation, combined with another equation, for $z \in \mathbb{R}$ and $\lambda(z) \in \mathbb{R}$,

$$\psi^B(z;x) = a(z)\psi^B(z;x) + b(z)\psi^m(z;x)$$

$$\psi^m(z;x) = \hat{b}(z)\psi^B(z;x) + \hat{a}(z)\psi^m(z;x). \tag{74}$$

These two equations are used to formulate jump conditions for a sectionally analytic function.

$^3$The necessary and sufficient condition is that $\Gamma$ is a Carleson curve [5].
Remark 3.3. To deduce properties of \( a, b, \hat{a}, \hat{b} \) we need only evaluate this relation at \( x = 0 \) and recall remark 2.1 and apply lemma 2.7 at \( x = 0 \), for example.

3.1.1. Jump relation for \( S^2 > C^2 \). First, note that \( \psi^m(-z; x) = \psi^P(z; x) \) since \( \lambda(z) \) is odd for \( z \notin (-c, c) \). Additionally, there is a conjugate symmetry because \( u_0 \) is real-valued: \( \overline{\psi^m(z; x)} = \overline{\psi^P(z; x)} \), and \( \overline{\psi^P/m(z; x)} \) enjoys the same symmetry. Thus, we find that \( \overline{b}(z) = b(-z) = \hat{b}(z) \) and \( a(z) = a(-z) = \hat{a}(z) \). We also know that \( \phi^P \) and \( \psi^m \) are analytic functions of \( z \) in the lower-half plane while the others, \( \phi^m \) and \( \psi^P \), are analytic in the upper-half plane. Define the sectionally-analytic function

\[
L_1(z) = L_1(z; x) := \begin{bmatrix} \psi^P(z; x) & \psi^m(z; x) \\ \phi^P(z; x) & \phi^m(z; x) \end{bmatrix} \quad \text{Im} \, z > 0,
\]

\[
L_1^+(z) = L_1^+(z; x) := \begin{bmatrix} \psi^P(z; x) & \psi^m(z; x) \\ \phi^P(z; x) & \phi^m(z; x) \end{bmatrix} \quad \text{Im} \, z < 0.
\]

Then assuming that \( a(z) \neq 0 \) for \( \text{Im} \, z > 0 \), we have for \( S^2 > C^2 \)

\[
L_1^+(z) = \begin{bmatrix} 1 - l \frac{b(z)}{a(z)} & \frac{1}{a(z)} \frac{\psi^m(z; x)}{\phi^P(z; x)} & 0 \\ 0 & 1 \frac{\psi^m(z; x)}{\phi^P(z; x)} & 1 \\ 1 - l \frac{b(z)}{a(z)} & \frac{1}{a(z)} \frac{\psi^m(z; x)}{\phi^P(z; x)} & 0 \\ 0 & 1 \frac{\psi^m(z; x)}{\phi^P(z; x)} & 1 \end{bmatrix} \begin{bmatrix} a(z) \\ 0 \\ 0 \\ 1 \end{bmatrix}.
\]

We now define

\[
K_1(z) = \begin{cases} L_1(z) \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} & \text{Im} \, z > 0, \\ L_1(z) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} & \text{Im} \, z < 0, \end{cases}
\]

which is analytic on \( \mathbb{C} \setminus \mathbb{R} \) and satisfies

\[
K_1^+(z) = K_1^-(z) \begin{bmatrix} 1 - |R_1(z)|^2 & -R_1(z) \\ R_1(z) & 1 \end{bmatrix}, \quad s^2 > C^2.
\]

3.1.2. Jump relation for \(-C \leq s \leq C\). We find that for \(-C \leq s \leq C\)

\[
\psi(s; x) := \lim_{\epsilon \downarrow 0} \psi^P(s + i\epsilon; x) = \lim_{\epsilon \downarrow 0} \psi^m(s - i\epsilon; x).
\]

Then, again for \(-C \leq s \leq C\) we define \( \tilde{a}(s) \) and \( \tilde{b}(s) \) by

\[
\psi(s; x) = \tilde{a}(s)\phi^P(s; x) + \tilde{b}(s)\phi^m(s; x),
\]

because \( \psi \) is a solution of (11). From this, it follows that

\[
K_1^+(s) = K_1^-(s) \begin{bmatrix} 0 & \tilde{a}(s) \\ \tilde{a}^*(s) & 0 \end{bmatrix}, \quad -C \leq s \leq C.
\]
But then we solve for $\tilde{b}$ and $\tilde{a}$ to find
\[
\begin{aligned}
\tilde{b}(s) &= \frac{W(\psi(s; \cdot), \phi^p(s; \cdot))}{2isz}, \\
\tilde{a}(s) &= \frac{W(\phi^m(s; \cdot), \psi(s; \cdot))}{2isz}.
\end{aligned}
\tag{82}
\]
Since both $\psi$ and $\phi^p$ have analytic continuations for $\text{Im} \, z < 0$, it follows that $\tilde{b}(z)$ has an analytic continuation for $\text{Im} \, z < 0$. And then for $\text{Im} \, z > 0$
\[
\tilde{b}(-z) = -\frac{W(\phi^m(-z; \cdot), \phi^p(-z; \cdot))}{2iz} = \frac{W(\phi^m(z; \cdot), \phi^p(z; \cdot))}{2iz} = a(z).
\tag{83}
\]
This implies that $a^+(s) = \tilde{b}^-(s) = \tilde{b}(-s)$. It also follows that $\tilde{a}(z) = a(z)$ for $\text{Im} \, z > 0$ so that $\tilde{a}^+(s) = a^+(s)$. So,
\[
K_1^+(s) = K_1^-(s) \begin{bmatrix} 0 & -\frac{a^+(s)}{a^+(s)} \\ \frac{a^+(s)}{a^+(s)} & 1 \end{bmatrix}, \quad -c \leq s \leq c.
\tag{84}
\]
To finish the setup of the RH problem we extend the definition of $R_1$ as
\[
R_1(s) = \begin{cases} \frac{b(s)}{a^+(s)} & s^2 > c^2, \\
\frac{a^+(s)}{a^+(s)} & -c \leq s \leq c, \end{cases}
\tag{85}
\]
and define
\[
N_1(z) = K_1(z) e^{-ik\sigma_3}, \quad z \notin \mathbb{R}.
\tag{86}
\]

**Remark 3.4.** This definition of $R_1(s)$ for $-c \leq s \leq c$ can be justified by noting that if $u_0$ decays exponentially so that $\hat{\phi}^m$ and $\phi^p/m$ have analytic extensions to a strip containing the real axis then, $b(z)$ has an extension to a set $(B \setminus [-c, c]) \cap C^+$ where $[-c, c] \subset B$, $B$ is open, and $R_1(s) = \frac{b^+(s)}{a^+(s)}$ for $-c \leq s \leq c$.

**Theorem 3.5 ([6, 8]).** For all $x \in \mathbb{R}$, componentwise, we have
\[
N_1(\cdot) - \begin{bmatrix} 1 & 1 \end{bmatrix} \in H_2^+(\mathbb{R}).
\tag{87}
\]

Using the jump conditions (78) and (81) satisfied by $K_1$ and the extension of $R_1$ given in (85) we have arrived at the following RH problem satisfied by $N_1$.

**Riemann–Hilbert Problem 1.** The function $N_1 : \mathbb{C} \setminus \mathbb{R} \to \mathbb{C}^{1 \times 2}$ is analytic on its domain and satisfies
\[
N_1^+(s) = N_1^-(s) \begin{bmatrix} 1 - |R_1(s)|^2 & -\overline{R_1(s)} e^{2ius} \\ \overline{R_1(s)} e^{-2ius} & 1 \end{bmatrix}, \quad s \in \mathbb{R}, \quad N_1(z) = \begin{bmatrix} 1 & 1 \end{bmatrix} + O(z^{-1}), \quad z \in \mathbb{C} \setminus \mathbb{R},
\tag{88}
\]
with the symmetry condition
\[
N_1(-z) = N_1(z) \sigma_3, \quad z \in \mathbb{C} \setminus \mathbb{R}.
\tag{89}
\]
Remark 3.6. While setting up this RH problem one verifies that
\[
\lim_{|z| \to \infty, \text{Im} z > 0} z \left( N_1(z) - \begin{bmatrix} 1 & 1 \end{bmatrix} \right) = \lim_{|z| \to \infty, \text{Im} z < 0} z \left( N_1(z) - \begin{bmatrix} 1 & 1 \end{bmatrix} \right),
\]
(90)
using lemmas 2.5 and 2.6. This is a necessary condition for the solution of a singular integral equation we pose below in (147) to have an integrable solution. We are purposefully vague about in what sense the limits $N_1^\pm$ exist as this is made precise below.

3.2. Right Riemann–Hilbert problem

We now use the other scattering relation, combined with yet another equation, for $z \in \mathbb{R}, A(z) \in \mathbb{R},$
\[
\phi^m(z; x) = B(z)\psi^P(z; x) + A(z)\phi^m(z; x),
\]
\[
\phi^P(z; x) = \tilde{A}(z)\psi^P(z; x) + \tilde{B}(z)\phi^m(z; x).
\]
(91)
We find that $B(z) = B(-z) = \tilde{B}(z)$ and $A(z) = A(-z) = \tilde{A}(z)$ and $A(z)$ has an analytic continuation into the upper-half plane. This is now used to determine the jump relations for another sectionally analytic function.

3.2.1. Jump relation for $s^2 \geq c^2$. Define the sectionally-analytic function
\[
L_2(z) = L_2(z; x) := \begin{bmatrix} \phi^m(z; x) & \psi^P(z; x) \end{bmatrix} \quad \text{Im} z > 0,
\]
\[
L_2^+(s) = \begin{bmatrix} \phi^m(s; x) & \psi^P(s; x) \end{bmatrix} = \begin{bmatrix} A(s) - \frac{B(s)A(s)}{A^2(s)} & \frac{B(s)A(s)}{A^2(s)} \psi^P(s; x) \phi^m(s; x) \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} \frac{A(s)}{A^2(s)} & -\frac{B(s)}{A(s)} \\ \frac{B(s)}{A(s)} & \frac{1}{A^2(s)} \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.
\]
(92)
Then assuming that $A(z) \neq 0$ for $\text{Im} z \geq 0$, we have for $s^2 \geq c^2$
\[
K_2(z) = \begin{bmatrix} L_2(z) & 0 \\ 0 & 1 \end{bmatrix} \quad \text{Im} z > 0,
\]
\[
K_2^+(s) = K_2(s) \begin{bmatrix} 1 - |R_t(s)|^2 & -R_t(-s) \\ R_t(s) & 1 \end{bmatrix}
\]
(93)
In a similar way as above define
\[
K_2(z) = \begin{bmatrix} L_2(z) & 0 \\ 0 & 1 \end{bmatrix} \quad \text{Im} z < 0
\]
(94)
so that for $s^2 \geq c^2$ we have the jump relation
\[
K_2^+(s) = K_2(s) \begin{bmatrix} 1 - |R_t(s)|^2 & -R_t(-s) \\ R_t(s) & 1 \end{bmatrix}.
\]
(95)
3.2.2. Jump relation for $-c \leq s \leq c$. For $-c \leq s \leq c$, the second entry of $L_2^+(s)$ is equal to the first entry of $L_2^-(s)$. From (80) it follows that

$$
\phi^m(s; x) = \frac{1}{a^+(s)}\psi(s; x) - \frac{a^+(s)}{a^+(s)}\phi^P(s; x).
$$

(96)

For $-c \leq s \leq c$ this gives the relations

$$
L_2^+(s) = L_2^-(s) \begin{bmatrix} \frac{1}{a^+(s)} & 1 \\ -\frac{a^+(s)}{a^+(s)} & 0 \end{bmatrix},
$$

(97)

which implies

$$
K_2^+(s) = K_2^-(s) \begin{bmatrix} \frac{1}{a^+(s)A^+(s)} & 1 \\ -\frac{a^+(s)A^+(s)}{A^+(s)A^+(s)} & 0 \end{bmatrix},
$$

(98)

and then

$$
K_2^+(s) = K_2^-(s) \begin{bmatrix} \frac{1}{a^+(s)A^+(s)} & 1 \\ -\frac{a^+(s)A^+(s)}{A^+(s)A^+(s)} & 0 \end{bmatrix}.
$$

(99)

The definition of $R_\epsilon(s)$ for $-c \leq s \leq c$ is much more complicated than for $R_1(s)$. We first establish an identity involving $R_\epsilon(s)$, $a^+(s)$, and $A^+(s)$ under the assumption that $\omega_0(x)$ decays exponentially as $x \to \pm \infty$ implying that there exists neighborhoods of $V_+$, $V_-$ of $c$ and $-c$, respectively, such that $R_\epsilon(s)$ has an analytic extension to $V_{\pm c} \setminus [-c, c]$. For $c > 0$ sufficiently small, and for $-c \leq s \leq -c + \epsilon$ we claim

$$
\lim_{\epsilon \downarrow 0} R_\epsilon(s + i\epsilon) - \lim_{\epsilon \uparrow 0} R_\epsilon(-(s - i\epsilon)) = \frac{1}{a^+(s)A^+(s)}.
$$

(100)

The left-hand side is equal to

$$
R_\epsilon^+(s) - R_\epsilon^-(s) = \frac{B^+(s)A^+(s) - B^+(s)A^+(s)}{A^+(s)A^+(s)}.
$$

(101)

We then use $a^+(s) = \frac{\lambda^+(s)}{\lambda^+(s)}A^+(s)$ to write

$$
R_\epsilon^+(s) - R_\epsilon^-(s) = -\frac{\lambda^+(s)}{\lambda^+(s)} \frac{B^+(s)A^+(s) - B^+(s)A^+(s)}{a^+(s)A^+(s)}.
$$

(102)

From the Wronskian representations we obtain $A^+(s) = -\frac{\lambda^+(s)}{\lambda^+(s)}b^+(s)$ from which it follows that

$$
R_\epsilon^+(s) - R_\epsilon^-(s) = \frac{B^+(s)b^+(s) + B^+(s)b^+(s)}{a^+(s)A^+(s)}.
$$

(103)

Then working with Wronskians for functions $f, g, h, k$ we find by brute force

$$
W(f, h)W(g, k) - W(g, h)W(f, k) = W(f, g)W(h, k).
$$

(104)

Then using that the boundary values from above of $\phi^m/s$ are even in $s$ and $\phi^P(-s; x) = \phi^m(s; x)$, we find that $B^+(s)b^+(s) + B^+(s)b^+(s) = 1$ and the claim (100) follows. Then, compute
\[
\begin{pmatrix}
1 & -R^+_{t}(s) \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
R^+_{t}(s) & 1
\end{pmatrix}
= \begin{pmatrix}
\frac{1}{a^+(s)} & 0 \\
\frac{1}{a^+(s)} & 1
\end{pmatrix}.
\]

(105)

Note that \(R^+_{t}(s)\) can be extended to an open set in the lower-half plane, \(R^+_{t}(s)\) can be extended to an open set in the upper-half plane. The same factorization holds near \(c\) on \([c - \epsilon, c]\).

Removing the assumption of exponential decay of \(u_0\), but keeping the condition \(u_0 \in L^1(\mathbb{R}, (1 + |x|)^3 \, dx)\), we extend the definition of \(R_t\) to \([-c, c]\) so that it has an approximate analytic extension. This extension is given by

\[
R_t(s) = \begin{cases}
\frac{B(s)}{A(s)} & s^2 \geq c^2, \\
\frac{\frac{1}{2} + \ell(s)}{a^+(s)A^+(s)} & -c + \epsilon \leq s \leq c - \epsilon, \\
\frac{B^+(s)}{A^+(s)} & s \in (-c, -c + \epsilon) \cup (c - \epsilon, c),
\end{cases}
\]

(106)

where \(\ell(s)\) is an even function of \(s\) on \((-c, c)\). The intent of this definition is for it to make sense even when \(\epsilon = 0\), and the third case never applies. Furthermore, we have

\[
R_t(s) - R_t(-s) = \frac{1}{a^+(s)A^+(s)}, \quad s \in (-c, c).
\]

(107)

Now choose \(\ell\) to match the behavior of \(R_t\) at \(-c\) in the following way. Set

\[
\ell(s) = \alpha s^2 + \beta \sqrt{c^2 - s^2},
\]

(108)

and assume

\[
\frac{1}{a^+(s)A^+(s)} = \kappa_1 \sqrt{s + c} + \kappa_2 (s + c) + O(|s + c|^{3/2})
\]

(109)

as \(s \to -c, s > -c\). Such an expansion is valid by lemma 2.7. We find

\[
\frac{\frac{1}{2} + \ell(s)}{a^+(s)A^+(s)} = -\kappa_1 \frac{\sqrt{c}}{\sqrt{2}} + \left(\frac{\kappa_1}{2} - \frac{\beta}{c} \frac{\sqrt{c}}{\sqrt{2}}\right) \sqrt{s + c} + O(|s + c|), \quad s \to -c, s > -c.
\]

(110)

We choose \(\alpha\) so that \(\frac{\alpha \sqrt{c}}{\sqrt{2}} = 1\) and choose \(\beta\) so that \(\frac{\kappa_1}{2} - \frac{\beta}{c} \frac{\sqrt{c}}{\sqrt{2}} = -i\gamma\) where \(\gamma\) is determined by

\[
R_t(s) = -1 + \gamma \sqrt{-s - c} + O(|s + c|), \quad s \to -c, s < -c.
\]

(111)

This process succeeds because \(\kappa_1 \neq 0\). This implies that

\[
R_t(s) = -1 + \gamma g(s) + O(|s + c|), \quad s \to -c, s < -c,
\]

(112)

where \(g(z) = \sqrt{-z - c}\) has an analytic extension to the upper-half plane, using the principal branch of the square root.

\footnote{The fact that \(\lim_{s \to -c, s < -c} R_t(s) = -1\) is established in theorem 3.13 below directly from a ratio of Wronskians.}
Then, as a consequence of \( R_\ell(-s) = \overline{R_\ell(s)} \), \( s^2 > c^2 \), and the fact that \( a^+(-s)A^+(s) \) is an odd function of \( s \), we have

\[
R_\ell(s) = -1 + i\gamma \sqrt{s - c + O(|s - c|)}, \quad s \to c, \quad s > c,
\]

\[
\frac{1}{a^+(-s)A^+(s)} = -\kappa_1 \sqrt{c-s} - \kappa_2(c-s) + O(|s-c|^3/2), \quad s \to c, \quad s < c,
\]

and therefore

\[
\frac{1}{s^2 - c^2} \left( \frac{\ell(s)}{i\sqrt{s-c}} \right) = -\kappa_1 \frac{\sqrt{c}}{\sqrt{2}} + \left( -\frac{\kappa_1}{2} - \kappa_1 \frac{\beta}{c} - \kappa_2 \frac{\sqrt{c}}{\sqrt{2}} \right) \sqrt{c-s} + O(|c-s|), \quad s \to c, \quad s < c,
\]

\[
= -1 + (-i\gamma - \kappa_1) \sqrt{c-s} + O(|c-s|), \quad s \to c, \quad s < c,
\]

\[
= -1 + i\gamma \sqrt{c-s} + O(|c-s|), \quad s \to c, \quad s < c,
\]

(113)

because the following lemma holds.

**Lemma 3.7.** If \( u_0 \in L^1(\mathbb{R}, (1 + |x|)^2 \, dx) \), \(-i\gamma - \kappa_1 = i\gamma_i \).

**Proof.** If the initial condition has compact support, we have local analytic continuations of \( R_\ell \) to the upper-half plane in the neighborhood of \( \pm c \) and therefore using that \( R_\ell(-z) = \overline{R_\ell(z)} \)

\[
R_\ell^+(s) = -1 - i\gamma \sqrt{s+c} + O(|s+c|), \quad s \to -c, \quad s > -c.
\]

\[
R_\ell^+(s) = -1 + i\gamma \sqrt{c-s} + O(|c-s|), \quad s \to c, \quad s < c.
\]

(115)

The identity

\[
R_\ell^+(s) - R_\ell^+(s) = \frac{1}{a^+(-s)A^+(s)},
\]

(116)

establishes the claim for initial data with compact support. For general data, we approximate it in \( L^1(\mathbb{R}, (1 + |x|)^2 \, dx) \) with data having compact support and then lemma 2.7 implies the claim in the limit because \( \gamma \) and \( \kappa_1 \) are continuous as functions on \( L^1(\mathbb{R}, (1 + |x|)^2 \, dx) \). \( \square \)

**Remark 3.8.** The definition of \( R_\ell \) on \([-c + c, c - c]\) can be modified, assuming \( u_0 \in L^1(\mathbb{R}, (1 + |x|)^{k+1} \, dx) \), so that more terms in its series expansion at \( \pm c \) match from the left and right.

We finally define

\[
N_2(z) = K_2(z) \, e^{i\lambda(z)u_\gamma}
\]

(117)

and arrive at the following problem satisfied by \( N_2 \).

**Riemann–Hilbert Problem 2.** The function \( N_2 : \mathbb{C} \setminus \mathbb{R} \to \mathbb{C}^{1 \times 2} \) is analytic on its domain and satisfies
with the symmetry condition
\[ N_2(\bar{z}) = N_2(z) e^{i\gamma}, \quad z \in \mathbb{C} \setminus \mathbb{R}. \] (118)

### 3.3. Decay properties of $R_{1/s}$ on $\mathbb{R}$

**Definition 3.9.** Define $\mathcal{D}_n$, $n \geq 2$ to be the class of functions $f$ on $\mathbb{R}$ such that $f \in L^1(\mathbb{R}; (1 + |x|) \, dx)$ has $n - 1$ absolutely continuous derivatives in $L^1(\mathbb{R})$, $f^{(n)}$ is piecewise absolutely continuous and in $L^1(\mathbb{R})$, and $f^{(n+1)} \in L^1(\mathbb{R})$.

If $n = 1$ define $\mathcal{D}_n$ to be the class of functions $f$ on $\mathbb{R}$ such that $f \in L^1(\mathbb{R}; (1 + |x|) \, dx)$, $f$ is absolutely continuous and $f^{(1)}$ is piecewise absolutely continuous and in $L^1(\mathbb{R})$, and $f^{(2)} \in L^1(\mathbb{R})$.

If $n = 0$ define $\mathcal{D}_n$ to be the class of functions $f$ on $\mathbb{R}$ such that $f \in L^1(\mathbb{R}; (1 + |x|) \, dx)$, $f$ is piecewise absolutely continuous and $f^{(1)} \in L^1(\mathbb{R})$.

**Lemma 3.10 ([19]).** For $n \geq 0$, suppose that $u_0 \in \mathcal{D}_n$. Then
\[ R_{1/s}(s) = O(|s|^{-2-n}), \quad \text{as } s \to \pm \infty. \] (119)

**Remark 3.11.** In [19] the author impose moment conditions on derivatives of $u_0$ in the proof of a more general version of lemma 3.10 that gives decay rates of the derivatives of the reflection coefficients. Since we only focus on the decay rate of the function itself in the present work, these conditions are unnecessary.

### 3.4. Relations between left and right scattering data

In some of the calculations that follow, it is convenient to have specific equalities that relate $A, B, a$ and $b$. First, consider the system (74) for $z \in \mathbb{R}$, $\lambda(z) \in \mathbb{R}$, combined with its derivative with respect to $x$

\[
\begin{bmatrix}
\phi^p(z; x) & \psi^m(z; x) \\
\phi^a(z; x) & \psi^m(z; x)
\end{bmatrix} =
\begin{bmatrix}
\phi^p(z; x) & \phi^m(z; x) \\
\phi^a(z; x) & \phi^m(z; x)
\end{bmatrix}
\begin{bmatrix}
a(z) & b(-z) \\
b(z) & a(-z)
\end{bmatrix}.
\] (120)
This gives
\[
a(z)a(-z) - b(z)b(-z) = \frac{W(\psi^P(z; \cdot), \psi^m(z; \cdot))}{W(\phi^P(z; \cdot), \phi^m(z; \cdot))} = \frac{\lambda(z)}{a(-z)},
\]
\[
A(z)A(-z) - B(z)B(-z) = \frac{z}{\lambda(z)}.
\]
From this, one finds,
\[
1 - R_l(z)R_l(-z) = \frac{\lambda(z)}{z} \frac{1}{a(-z)a(z)} = \frac{1}{A(z)a(-z)}.
\]
Next, we claim that for \( z \in \mathbb{R} \), \( \lambda(z) \in \mathbb{R} \)
\[
B(z) = - \frac{b(-z)A(-z)}{a(-z)} = -b(-z)\frac{z}{\lambda(z)}.
\]
This follows because \( \psi^P(-z; \cdot) = \psi^m(z; \cdot), \ phi^P(-z; \cdot) = \phi^m(z; \cdot), \) and \( A(z) = a(z)\frac{z}{\lambda(z)} \).

3.5. Smoothness properties of \( R_l \) on \( \mathbb{R} \)

**Definition 3.12.** The initial perturbation \( u_0(x) = u(x, 0) - H_c(x) \) is said to be generic if
\[
W(\psi^m(c; \cdot), \psi^P(c; \cdot)) \neq 0 \quad \text{and} \quad W(\phi^m(0; \cdot), \phi^P(0; \cdot)) \neq 0.
\]
The term genericity is used because this is expected to hold on a open, dense subset of initial data [8]. We note that this fact was not established in [19]. We do not establish this here because we can verify it numerically in all cases we consider. It will be considered in a future work.

Genericity implies, by evaluating at \( x = 0 \),
\[
W(\phi^m(c; \cdot), \phi^P(0; \cdot)) \neq 0,
\]
giving
\[
0 \neq W(\psi^m(c; \cdot), \psi^P(0; \cdot)) = W(\phi^P(c; \cdot), \psi^m(0; \cdot)) = W(\phi^m(-c; \cdot), \psi^P(0; \cdot)).
\]
Next, by again evaluating at \( x = 0 \),
\[
0 \neq W(\psi^m(0; \cdot), \phi^P(0; \cdot)) = W(\phi^P(c; \cdot), \phi^P(0; \cdot)).
\]
Here \( \psi^m \) and \( \phi^P \) are solutions of the same Schrödinger equation with decaying potential \( u_0(x) \).

We find that (127) with \( u_0(x) \) replaced with \( u_0(-x) \) is the same condition as (126).

**Theorem 3.13.** Suppose that \( k \) is a non-negative integer and \( u_0 \in L^1(\mathbb{R}, (1 + |x|)^{k+1}|dx) \) and assume \( u_0 \) is generic. Then \( R_l(s) \) satisfies
\[
R_l(s) = \sum_{j=0}^{k} c_j \left( \sqrt{s-c} \right)^j + o(|s + c|^{k/2}), \quad s \to -c, \ s < -c,
\]
\[
R_l(s) = \sum_{j=0}^{k} \tilde{c}_j \left( \sqrt{s-c} \right)^j + o(|s + c|^{k/2}), \quad s \to -c, \ s > -c,
\]
\footnote{A similar condition at \( s = c \) is implied by \( R_l(-s) = R_l(s) \).}
and \( c_j = \hat{c}_j \) for \( j = 0, 1, \ldots, k \). Furthermore, \( R_{1/\varepsilon} \) are \( C^k \) functions on \( \mathbb{R} \setminus \{c, -c\} \) satisfying
\[
R_{\varepsilon}(\pm c) = -1, \quad R_{1}(0) = -1.
\] (129)

**Proof.** Recall that from (25) and (85)
\[
R_{1}(s) = \begin{cases} \frac{k(s)}{a(s)} & |s| > c, \\ \frac{a^{+}(-s)}{a^{+}(s)} & |s| \leq c. \end{cases}
\] (130)

Consider the truncation \( u_{0,L}(x) = u_{0}(x)X_{\{|x| \leq L\}}(x), L > 0 \), which has compact support so that
\[
R_{1}(s; L) = \sum_{j=0}^{k} \hat{c}_{j,L}(\sqrt{-s-c})^{j} + o(|s+c|^{k/2}), \quad s \to -c, s < -c,
\]
and \( \hat{c}_{j,L} = \hat{c}_{j,L} \) for \( j = 0, 1, \ldots, k \). Next, we show that these expressions remain valid as \( L \to \infty \), implying (128). Indeed this follows by lemma 2.7 as the limit can be applied term-by-term in the Taylor expansion. A similar argument holds at \(+c\). The argument for \( R_{\varepsilon} \) is simpler as once we know the Taylor expansions exist, (106) gives the result.

Now,
\[
a^{+}(s) = \frac{W(\psi^{m}(s; \cdot), \phi^{P}(s; \cdot))}{2is}
\] (132)
so that for \( s \neq 0 \) we have
\[
\frac{a^{+}(s)}{a^{+}(-s)} = \frac{W(\psi^{m}(s; \cdot), \phi^{P}(s; \cdot))}{W(\psi^{m}(-s; \cdot), \phi^{P}(-s; \cdot))}.
\] (133)

Then, under the condition that \( W(\psi^{m}(0; \cdot), \phi^{P}(0; \cdot)) \neq 0 \) we find that \( R_{1}(0) = -1 \). Then to establish the required equalities at \( \pm c \) we consider for \( s^{2} > c^{2} \), assuming the corresponding denominators do not vanish
\[
R_{\varepsilon}(\pm c) = \frac{W(\dot{\psi}^{m}(\pm c; \cdot), \dot{\phi}^{m}(0; \cdot))}{W(\psi^{m}(\pm c; \cdot), \phi^{P}(0; \cdot))}.
\] (134)

But then \( \dot{\phi}^{P}(0; \cdot) = \dot{\psi}^{m}(0; \cdot) \) so that \( R_{\varepsilon}(\pm c) = 1 \).

\[
R_{\varepsilon}(\pm c) = \frac{W(\dot{\phi}^{P}(0; \cdot), \phi^{P}(\pm c; \cdot))}{W(\dot{\psi}^{P}(0; \cdot), \phi^{m}(\pm c; \cdot))}.
\] (135)

### 3.6. The final Riemann–Hilbert problems

To finalize the setup of the RH problems, we must introduce time-dependence and residue conditions from the existence of solitons in the solution whenever \( a(z) \) has a simple zero. This
process is detailed in appendix A. Specifically, it follows from the decay assumptions on $u_0$ that $a(z) = a(z; 0)$ does not vanish on $\mathbb{R}$ and has a finite number of simple poles $\{z_1, \ldots, z_n\}$ in the open upper-half plane, all lying on the imaginary axis [6]. Then define $\Sigma_1, \ldots, \Sigma_n$ to be disjoint circular contours in the open upper-half plane of radius $\delta > 0$ with $z_1, \ldots, z_n$ as their centers and clockwise orientation. Additionally, give $-\Sigma_j := \{ z : z \in \Sigma_j \}$ counter-clockwise orientation.

**Riemann–Hilbert Problem 3.** The function $N_1 : \mathbb{C} \setminus \mathbb{R} \to \mathbb{C}^{1 \times 2}$, $N_1(z) = N_1(z; x, t)$ is analytic on its domain and satisfies

$$
N_1^+(s) = N_1^-(s) \begin{bmatrix} 1 - |R_1(s)|^2 & -R_1(-s) e^{2ixs + 8is^3t} \\ R_1(s) e^{-2ixs - 8is^3t} & 1 \end{bmatrix}, \quad s \in \mathbb{R},
$$

$$
N_1^+(s) = N_1^-(s) \begin{bmatrix} \frac{1}{s - \gamma} e^{-2i\gamma s - 8i\gamma^3 s^3 t} & 0 \\ \frac{e^{-2i\gamma s - 8i\gamma^3 s^3 t}}{s - \gamma} & 1 \end{bmatrix}, \quad s \in \Sigma_j,
$$

$$
N_1^+(s) = N_1^-(s) \begin{bmatrix} 1 & -\frac{c(\gamma)}{s + \gamma} e^{-2i\gamma s - 8i\gamma^3 s^3 t} \\ \frac{e^{-2i\gamma s - 8i\gamma^3 s^3 t}}{s + \gamma} & 1 \end{bmatrix}, \quad s \in -\Sigma_j,
$$

with the symmetry condition

$$
N_1(-z) = N_1(z) \sigma_1, \quad z \in \mathbb{C} \setminus \mathbb{R}, \quad \Gamma = \mathbb{R} \cup \bigcup_j (\Sigma_j \cup -\Sigma_j).
$$

**Theorem 3.14.** There exists a unique $L^2$ solution of RH problem 3 provided $R_1$ is any function on $\mathbb{R}$ that is continuous and square-integrable, decays at infinity, and satisfies $R_1(-s) = R_1(s)$.

For the proof of theorem 3.14, see appendix B.1.

**Riemann–Hilbert Problem 4.** The function $N_2 : \mathbb{C} \setminus \mathbb{R} \to \mathbb{C}^{1 \times 2}$, $N_2(z) = N_2(z; x, t)$ is analytic on its domain and satisfies

$$
N_2^+(s) = N_2^-(s) \begin{bmatrix} 1 - |R_2(s)|^2 & -R_2(-s) e^{2ixs + 8is^3t} \\ R_2(s) e^{-2ixs - 8is^3t} & 1 \end{bmatrix}, \quad s^2 > c^2,
$$

$$
N_2^+(s) = N_2^-(s) \begin{bmatrix} 1 & 0 \\ -R_2(-s) e^{-2i\lambda^-(s) x - 8i\lambda^-(s)^3 t} & 1 \end{bmatrix} \sigma_1 \begin{bmatrix} 1 & 0 \\ R_2(s) e^{2i\lambda^+(s) x + 8i\lambda^+(s)^3 t} & 1 \end{bmatrix}, \quad -c \leq s \leq c,
$$

$$
N_2^+(s) = N_2^-(s) \begin{bmatrix} 1 & 0 \\ -\frac{c(\gamma)}{s + \gamma} e^{-2i\lambda^+(s) x - 8i\lambda^+(s)^3 t} & 1 \end{bmatrix}, \quad s \in \Sigma_j,
$$

$$
N_2^+(s) = N_2^-(s) \begin{bmatrix} 1 & 0 \\ -\frac{c(\gamma)}{s + \gamma} e^{2i\lambda^+(s) x + 8i\lambda^+(s)^3 t} & 1 \end{bmatrix}, \quad s \in -\Sigma_j,
$$

$$
\varphi(s) = \lambda(s)^3 + \frac{3}{2} c^2 \lambda(s),
$$

with the symmetry condition

$$
N_2(-z) = N_2(z) \sigma_1, \quad z \in \mathbb{C} \setminus \mathbb{R}.
$$
Theorem 3.15. Assume

(1) \(a, b, A, B : \mathbb{R} \setminus [c, \infty) \rightarrow \mathbb{C}\) are 1/2-Hölder continuous functions such that \(a(s)\) and \(b(s)\),
can be extended to 1/2-Hölder continuous functions on \(\mathbb{R} \setminus (-c, \infty)\).
(2) The symmetries (122) and (123) hold for \(s^2 > c^2\).
(3) For \(s^2 > c^2\), \(\pi(s) = a(-s)\) and \(\overline{b(s)} = \overline{b(-s)}\).
(4) \(a^+ \cdot A^+: (-c, c) \rightarrow \mathbb{C}\) are 1/2-Hölder functions such that \(sa^+(s)\), \(\lambda_+(s)A^+(s)\) can be
extended to 1/2-Hölder continuous functions on \([-c, c]\) and \(a^+(\pm c) = a(\pm c)\).
(5) \(a, b\) satisfy
\[
\begin{align*}
a(s) &= \alpha_{1,-} + \alpha_{2,-}\sqrt{s-c} + O(|s + c|), \quad s \rightarrow -c, \quad s^2 > c^2, \\
b(s) &= -\alpha_{1,-} + \beta_{2,-}\sqrt{s-c} + O(|s + c|), \quad s \rightarrow -c, \quad s^2 > c^2, \\
a(s) &= \alpha_{1,+} + \alpha_{2,+}\sqrt{s+c} + O(|s - c|), \quad s \rightarrow c, \quad s^2 > c^2, \\
b(s) &= -\alpha_{1,+} + \beta_{2,+}\sqrt{s+c} + O(|s - c|), \quad s \rightarrow c, \quad s^2 > c^2,
\end{align*}
\]
for some \(\alpha_{j,\pm}, \beta_{j,\pm} \in \mathbb{C}\).
(6) \(a^+\) satisfies
\[
\begin{align*}
a^+(s) &= \xi_{1,-} + \xi_{2,-}\sqrt{s+c} + O(|s + c|), \quad s \rightarrow -c, \quad s > -c, \\
a^+(s) &= -\xi_{1,-} + \xi_{2,+}\sqrt{s-c} + O(|s - c|), \quad s \rightarrow c, \quad s < c,
\end{align*}
\]
for some \(\xi_{1,-}\) and \(\xi_{2,+} \in \mathbb{C}\).
(7) \(A^+(s) = a^+(s) R_s(z)\) for \(s \in (-c, c)\).
(8) Neither \(a(s)\) nor \(sa^+(s)\) vanish within their domains of definition.
(9) \(R_s(x)\) is given by (85).
(10) \(R_s(x)\) is given by (106), and (112) and (114) hold.
(11) \(R_{s/t}(s) = O(s^{-1})\) as \(|s| \rightarrow \infty\).

Then there exists a unique \(L^2\) solution of RH problem 4.

For the proof of theorem 3.15, see appendix B.2 of the appendix. We can now prove our
theorem about the existence of solutions of the KdV equation via RH problems.

Theorem 3.16. Suppose \(u_0\) is generic. Then the following hold:

(1) If \(u_0 \in L^1(\mathbb{R}, (1 + |x|) \, dx)\) then RH problem 3 has a unique solution.
(2) If \(u_0 \in L^1(\mathbb{R}, (1 + |x|)^3 \, dx)\) then RH problem 4 has a unique solution.
(3) If either \(u(\cdot, 0) \in D_3\) or \(u_0 \in L^1(\mathbb{R}, e^{j|\xi|} \, dx)\) for some \(\delta > 0\) then by the dressing method
these solutions produce the solution of the KdV equation for \(t > 0\):
\[
\lim_{z \rightarrow \infty} 2i\pi(N_1(z) - [1 1]) = \left[-\int_{-\infty}^{\infty} u(x', t) \, dx'\right] + \int_{-\infty}^{\infty} u(x', t) \, dx',
\]
\[
\lim_{z \rightarrow \infty} 2i\pi(N_2(z) - [1 1]) = \left[-\int_{-\infty}^{\infty} [u(x', t) + c_2^2] \, dx'\right] + \int_{-\infty}^{\infty} [u(x', t) + c_2^2] \, dx'.
\]

Proof. Parts (1) and (2) follow from lemma 2.7 and theorems 3.14 and 3.15. Part (3) is the
application of the dressing method and the conditions imposed are sufficient for the solution
of the RH problem to be differentiable both in \(x\) and \(t\) the required number of times. For
\(u(\cdot, 0) \in D_3\) see lemma 3.10 and for \(u_0 \in L^1(\mathbb{R}, e^{j|\xi|} \, dx)\), see the deformations in section 6
which induces exponential decay of the jump matrix. 

□
Remark 3.17. It is important to note that if one solves RH problem 3 for large values of $x$, the recovery formula (142) produces a quantity that grows as $x$ increases. This indicates that the operator one is inverting is not well-conditioned in this limit. Thus there is a reason based on numerical stability for including both RH problems 3 and 4.

4. Contour deformations and numerical inverse scattering

Throughout this section we assume $u_0 \in L^1(\mathbb{R}^+ |x| \, dx)$ for some $\nu > 0$. This immediately implies that, in addition to other analyticity properties, $\phi^{p/m}$ and $\hat{\phi}^{p/m}$ and their $x$-derivatives have analytic extensions as functions of $z$ within the open strip $S_\nu := \{z \in \mathbb{C} : \text{Im} \lambda(z) < \nu \}$. Define

$$S_\lambda^\nu = \{z \in \mathbb{C} : \text{Im} \lambda(z) < \nu \}. \quad (143)$$

See figure 2 for a plot. It is clear that $\Re \setminus [-c, c] \subset S_\lambda^\nu$ for any choice of $\lambda$. Then, for example, it follows that $\psi^p(z; x)$ is an analytic function of $z$ within the region

$$S_\nu^{p,+} := C^+ \cup S_\nu^\lambda \setminus [-c, c], \quad (144)$$

while $\psi^m(z; x)$ is an analytic function of $z$ within the region

$$S_\nu^{m,-} := C^- \cup S_\nu^\lambda \setminus [-c, c]. \quad (145)$$

It then follows that $R_l(s)$ has a meromorphic extension to $S_\nu^{p,+}$ while $R_r(s)$ has a meromorphic extension to only $S_\nu^{p,+} \cap S_\nu^{m,-}$. These regions of analyticity are sufficient to make all the deformations outlined below.

4.1. Computing $R_{r/l}$

We note that the computation of the reflection coefficients is no different than that in the case of decaying data [40]. Indeed, we compute the scattering data by evaluating at $x = 0$, see remark 2.1.
4.2. Computing \( \{z_j\}, C(z_j) \) and \( c(z_j) \)

The authors in [40] used Hill’s method [7] to compute the (negative) eigenvalues of the operator (11) at \( t = 0 \) and therefore find the zeros \( a(z) \) in the upper-half plane. This required initial data with decay, so that one can approximate the eigenvalues with those from an operator on a space of periodic functions. Here, we choose \( L > 0 \) so that \( |u_0(x)| < \epsilon \) for \( |x| > L \) and \( \epsilon \) is on the order of machine precision. Then (11) can be approximated by

\[
-D_{N,L}^2 - \text{diag} u(\tilde{x}_{N,L}, 0)
\]

where \( D_{N,L} \) is the first-order Chebyshev differentiation matrix [35] for \( \tilde{x}_{N,L} \), the vector of \( N \)th-order Chebyshev points scaled to the interval \([-L, L]\). For sufficiently large \( L, N \), the eigenvalues of (146) near the negative real axis approximate the eigenvalues of (11).

4.3. The numerical solution of Riemann–Hilbert problems

The numerical solution of an \( L^2 \) RH problem is based around the representation of \( H^2_\Omega(\Gamma) \) functions as the Cauchy integral of \( L^2(\Gamma) \) functions and consequently, the equivalency between solving the RH problem for \( N \) and solving the singular integral equation

\[
\mathbf{u} - C_\Gamma \mathbf{u} \cdot (\mathbf{G} - \mathbf{I}) = \mathbf{G} - \mathbf{I}, \quad \mathbf{N} = C_\Gamma \mathbf{u} + \mathbf{I}.
\]

This integral equation is discretized (see [31, 39]) using mapped Chebyshev polynomials. Suppose

\[
\Gamma = \bigcup_{\ell = 1}^{s} \Gamma_\ell,
\]

where \( \Gamma_\ell = M_\ell([-1, 1]) \) and \( M_\ell(x) = a_\ell x + b_\ell \) is an affine function. Then we construct a basis of \( L^2(\Gamma_\ell) \) denoted \( (\phi_j^{(\ell)})_{j \geq 0} \) and defined by

\[
\phi_j^{(\ell)}(x) = T_j \circ M_\ell^{-1}(x), \quad j = 0, 1, 2, \ldots, m_\ell(n), \ldots,
\]

where \( T_j(\cos \theta) = \cos j\theta \) is the \( j \)th Chebyshev polynomial of the first kind. The integer \( m_\ell(n) \) allows one to use a different number of basis functions on each \( \Gamma_\ell \). It is simple to check that

\[
\frac{1}{2\pi i} \int_{\Gamma_\ell} \frac{f(s)}{s - z} \, dz = \frac{1}{2\pi i} \int_{\Gamma_\ell} \frac{f(M_\ell(x))}{x - M_\ell^{-1}(z)} \, dx.
\]

Define the finite-dimensional space

\[
X_n = \left\{ f \in L^2(\Gamma) : f|_{\Gamma_\ell} \in \text{span}\{\phi_0^{(\ell)}, \ldots, \phi_{m_\ell(n)}^{(\ell)}\} \right\}.
\]

Provided that one can compute

\[
C_{[-1, 1]} \phi_j^{(\ell)}, \quad z \notin [-1, 1] \quad \text{and} \quad C_{[-1, 1]} \phi_j^{(\ell)}, \quad x \in (-1, 1),
\]

one can compute \( C_{\Gamma_\ell} \phi_j^{(\ell)} \) and \( C_{\Gamma_\ell} \phi_j^{(\ell)} \) away from the endpoints of \( \Gamma_\ell \). We then define a subspace \( X_n^{(0)} \) of \( X_n \) where we impose the condition

\[
f \in X_n^{(0)} \quad \text{if and only if} \quad f \in X_n \text{ and } \sup_{z \notin \Gamma} |C_{\Gamma} f(z)| < \infty.
\]
This imposes a condition on function values at all endpoints or self-intersection points of $\Gamma$ called the zero-sum condition, see [39, definition 2.47]. Then, with this condition one can show that $C_+ \Gamma f, f \in X_n^{(0)}$ is well defined for every point in $\Gamma$. There then exists an interpolatory projection $P_n$, derived via the discrete cosine transform, that maps

$$\{ f \in L^2(\Gamma) : |f|_{M_\ell((-1,1))} \text{ is continuous and extends continuously to } \Gamma_\ell, \ell = 1, 2, \ldots, S \}$$

onto $X_n$. All these considerations extend trivially to vector- or matrix-valued functions. In order to compute an approximate solution of an RH problem $(G, \Gamma)$, one then looks for a solution $u_n$ of

$$P_n(u_n - C_+ \Gamma u_n \cdot (G - I)) = P_n(G - I), \quad u_n \in X_n^{(0)}. \quad (150)$$

Careful study of this system would lead one to think it is overdetermined but if $G$ satisfies the product condition [39, definition 2.55] this is not true [39, lemma 6.11]. An implementation of this methodology for finding $u_n$ can be found in RHPackage [30].

The convergence rate is closely tied to the smoothness of solutions [32] and invertibility of the associated operator on high-order Sobolev spaces is required [39]. Fortunately, this is immediate following theorems 3.14 and 3.15, and the fact that the jump matrix $G$ we encounter, after deformation, will satisfy the $k$th-order product condition [39, definition 2.55] for every $k$. If the solution is known to be analytic then the convergence rate as $n \to \infty$ is exponential, provided that the condition number of the linear system constructed in the solution of (150) grows at an (at most) polynomial rate [39, Assumption 7.4.1].

The deformation of a RH problem is an explicit transformation $(G, \Gamma) \mapsto (\tilde{G}, \tilde{\Gamma})$ such the solutions of the two problems are in correspondence. The goal is for the operator $u \mapsto u - C_+ \Gamma u \cdot (G - I)$ to be better conditioned than the original operator (147), i.e. have a smaller condition number. To have any analytic expressions for the solution, one needs the condition number to tend to one in an asymptotic limit, while numerically, one just aims to have a bounded quantity.

4.4. Recovery of $u(x, t)$

Once the solution of (147) has been computed, one then seeks $\partial_x u = u_x$, see (142). To do this, we solve the equation satisfied by $u_x$:

$$u_x - C_+ \Gamma u_x \cdot (G - I) = (C_+ \Gamma u + I)G_x, \quad N_x = C_+ \Gamma u_x. \quad (151)$$

And then, formally,

$$\lim_{z \to \infty} zN_x(z) = -\frac{1}{2\pi i} \int_{\Gamma} u_x(s) \, ds. \quad (152)$$

Assuming the operator in (147) is invertible, these formal manipulations are justified provided $G_x \in L^1 \cap L^\infty(\Gamma)$ and $C_+ \Gamma u + I \in L^\infty(\mathbb{R})$.

5. Numerical inverse scattering at $t = 0$

We divide this computation into two cases, $x < 0$ and $x \geq 0$. We first ignore the jumps on the contours $\Sigma_j, -\Sigma_j$. 

2238
Under our assumptions, $R_l$ has a meromorphic extension to $\nu \geq \Im z > 0$, decaying at infinity within this strip. And because $R_l$ has a finite number of poles in this strip, we can use the factorization

$$
\begin{bmatrix}
1 - R_l(s) R_l(-s) & R_l(-s) e^{-2i\alpha x} \\
-R_l(s) e^{2i\alpha x} & 1
\end{bmatrix} = M_1(s) P_1^{-1}(s) = \begin{bmatrix} 1 & R_l(-s) e^{-2i\alpha x} \\
0 & 1
\end{bmatrix} \begin{bmatrix} 1 & 0 \\
-R_l(s) e^{2i\alpha x} & 1
\end{bmatrix},
$$

(153)

noting that $\overline{R_l(s)} = R_l(-s)$, to deform RH problem 3 within a possibly smaller strip $\alpha \leq \delta$.

One does this by the so-called lensing process: given $N_1$ define

$$
N_1(z) = \begin{cases}
N_1(z) P_1(z) & 0 < \Im z < \alpha, \\
N_1(z) M_1(z) & -\alpha < \Im z < 0,
\end{cases}
$$

(154)

and then $N_1(z)$ satisfies the RH problem depicted in figure 3. The jumps matrices decay exponentially to the identity matrix as $x \to -\infty$. 

---

**Figure 3.** The initial deformation of RH problem 3 for $t = 0$, $x < 0$. The jumps on the contours $\Sigma_j$ and $-\Sigma_j$ surrounding the poles $z_j$ and $-z_j$ are unchanged at this stage. The matrices $M_1$ and $P_1^{-1}$ are the resulting jump matrices supported on the indicated arcs.

**Figure 4.** The initial deformation of RH problem 4 for $t = 0$, $x \geq 0$. The jumps on the contours $\Sigma_j$ and $-\Sigma_j$ surrounding the poles $z_j$ and $-z_j$ are unchanged at this stage. The matrices $J_2$, $M_2^{\pm 1}$, and $P_2^{\pm 1}$ are the resulting jump matrices supported on the indicated arcs.
5.2. $x \geq 0$

The situation for $x \geq 0$ is more complicated because the jump condition in RH problem 4 is discontinuous. Furthermore, we can only lens the jump matrix within as subregion of $\Sigma_\lambda$. See figure 4 for a depiction of the jump contours and jump matrices after lensing. But this RH problem, even though it is uniquely solvable in an $L^2$ sense, has a jump matrix that is not smooth, in the sense of the product condition [39, definition 2.55] at $\pm c$. A local deformation is required, using (B.37) below with jump matrices and jump contours depicted in figure 4. Then define two neighborhoods $B_{\pm c}$ of $\pm c$, by first defining $B_{c}$ shown in figure 5 and setting $B_{-c} = \{ -z : z \in B_{c} \}$. Now, define a new unknown

$$\hat{N}_2(z) = \tilde{N}_2(z) \begin{cases} W^{+1} & z \in B_{\pm c}, \\ 1 & \text{otherwise} \end{cases}$$

(155)

where $W$ is defined in (B.37). We point out that this definition is made to both solve the jump on the small intervals near $\pm c$ and to preserve the symmetry condition: if a function satisfies $N(-z) = N(z)\sigma_1$ and we want a new function $\tilde{N}(z) = N(z)C(z)$ to satisfy the same condition, then:

$$\tilde{N}(-z) = N(-z)C(-z) = N(z)\sigma_1C(-z),$$

(156)

and one concludes that $\sigma_1C(-z) = C(z)\sigma_1$ is a sufficient condition. In the case of $W$, we see that $\sigma_1W^{-1}(-z)\sigma_1 = W(z)$.

5.3. Jump matrices on $\Sigma_j$

Consider a RH problem with jump conditions the form

$$N^+(s) = N^-(s) \begin{cases} \begin{bmatrix} 1 & 0 \\ \tau^{-1} & 1 \end{bmatrix} & s \in \Sigma_j, \\ \begin{bmatrix} 1 & \beta \\ \tau^{-1} & 0 \end{bmatrix} & s \in -\Sigma_j. \end{cases}$$

(157)
Define
\[
Q(z) = \begin{bmatrix}
\frac{z - z_j}{z + z_j} & 0 \\
0 & \frac{z + z_j}{z - z_j}
\end{bmatrix},
\]
\[
M(z) = N(z) T(z; z_j, \alpha, \beta),
\]
and
\[
T(z; z_j, \alpha, \beta) = \begin{cases}
Q(z) & \text{z outside } \Sigma_j \text{ and } -\Sigma_j, \\
\begin{bmatrix}
\frac{z - z_j}{z + z_j} & \frac{1}{\alpha(z + z_j)} \\
-\alpha(z + z_j) & 0
\end{bmatrix} & \text{z inside } \Sigma_j, \\
\begin{bmatrix}
0 & \beta(z - z_j) \\
-\beta(z - z_j) & \frac{z + z_j}{z - z_j}
\end{bmatrix} & \text{z inside } -\Sigma_j.
\end{cases}
\]

Then the jump conditions satisfied by \( M(z) \) are given by
\[
M^+(s) = M^-(s) \begin{cases}
Q^{-1}(s) \begin{bmatrix}
\frac{1}{\alpha} & 0 \\
-\alpha(s + z_j) & \frac{1}{\alpha(s + z_j)}
\end{bmatrix} & s \in \Sigma_j, \\
\begin{bmatrix}
\frac{s + z_j}{\alpha(s + z_j)} & -\beta(s - z_j) \\
1 & \frac{1}{\alpha(s + z_j)}
\end{bmatrix} & s \in -\Sigma_j.
\end{cases}
\]

When \( \alpha \) and \( \beta \) are both large, this transformation allows us to convert the jump to one that is near-identity. We will only need to apply this transformation in the case \( \alpha = \beta \), in which case we use the notation \( T(z; z_j, \alpha) = T(z; z_j, \alpha, \beta) \).

To see how to employ this in the context of the KdV equation define two index sets, depending on \( x \) and \( t \)
\[
S_1(x, t) = \{ j : |c(z_j) e^{-2i\lambda_j(z_j)}| > 1 \}, \quad S_2(x, t) = \{ j : |C(z_j) e^{-2i\lambda_j(z_j) - 8i\rho(z_j)}| > 1 \},
\]
and two matrix functions defined on \( \mathbb{C} \setminus (\bigcup_j (\Sigma_j \cup -\Sigma_j)) \)
\[
Q_1(z) = \prod_{j \in S_1(x, t)} T(z; z_j, -c(z_j) e^{-2i\lambda_j(z_j)}), \quad Q_2(z) = \prod_{j \in S_2(x, t)} T(z; z_j, -C(z_j) e^{-2i\lambda_j(z_j) - 8i\rho(z_j)}).
\]

Our final step before solving the RH problem for \( \mathbf{N}_j \) will be to instead consider the RH problem for \( \mathbf{N}_j Q \). This includes our calculations for \( t > 0 \) below. We do not present the final RH problem, after this modification, as the preceding calculations allow one to directly derive the new jumps.
6. Numerical inverse scattering for two asymptotic regions

We now discuss simple deformations that lead to asymptotically accurate computations in two regions. The full deformation of the RH problem to compute asymptotic solutions in the entire \((x, t)\)-plane will be presented in a forthcoming work.

6.1. \(x \geq -2c^2 t\)

We begin with a simple but important calculation. For \(s \in (-c, c)\) and \(\zeta \in \mathbb{R}\) consider

\[
h(s) = 2i\lambda^+(s)\zeta + 8i\phi^+(s) = -\sqrt{c^2 - s^2} \left[ 2\zeta + 12c^2 - 8(c^2 - s^2) \right].
\]

This function, evidently, has a local minimum at \(s = 0\) where \(h(0) = -|c|(2\zeta + 4c^2)\). This remains non-positive provided that \(\zeta \geq -2c^2\). Thus the jump in RH problem 4 on \((-c, c)\) has its \((1, 1)\) entry less than unity, in absolute value, provided that \(x \geq -2c^2 t\). For this regime, we can use the deformation depicted in figures 5 and 6, using RH problem 4.

Before the deformed RH problem is solved numerically, the deformation detailed in section 5.3 is performed.

6.2. \(\sqrt{\frac{x}{\pi c + \delta}} > c + \delta\)

In this region we use RH problem 3 exclusively. Recalling that \(\mathcal{R}_l(s) = R_l(-s)\) we consider, formally,

\[
\begin{pmatrix}
1 - R_l(s)R_l(-s) & R_l(-s)e^{-2i\lambda x - 8is^3}\gamma \\
-R_l(s)e^{2i\lambda x + 8is^3}\gamma & 1
\end{pmatrix}
= M_l(s)P_l^{-1}(s) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}
\]

\[
= L(s)D(s)U^{-1}(s) = \begin{pmatrix}
1 \quad R_l(-s)e^{-2i\lambda x - 8is^3}\gamma \\
0 & \frac{T(s)}{1/T(s)}e^{-2i\lambda x - 8is^3}\gamma
\end{pmatrix}.
\]

Figure 6. A zoomed view of the second deformation of RH problem 4 for \(t = 0, x > 0\). All contours intersecting the real axis make the same angle with the real axis. The angle \(\pi/3\) is chosen so that \(e^{\pm i\lambda^3(z)}\) decays exponentially, for large \(z\), in the appropriate quadrants.
The jump contours and jump matrices for the unknown $\hat{N}_1$ defined in (167). The contours are deformed within a strip of width 2$\alpha$. The matrices $U^{\pm 1}$, $D$, $L$, $M_1^{\pm 1}$, and $P_1^{-1}$ are the jump matrices supported on the indicated arcs.

with

$$T(s) := 1 - |R_l(s)|^2 = 1 - R_l(s)R_l(-s).$$  \hspace{1cm} (165)

The first factorization is valid for $s \in \mathbb{R}$. The second factorization fails when $|R_l(s)| = 1$ which occurs for $s \in [-c, c]$. 

As is customary, we use the stationary phase points $z^* = \pm \sqrt{-x/(12\pi)}$ to guide the deformation. Given $\alpha > 0$ define six polygonal regions in $\mathbb{C}$:

\begin{align*}
\Omega_1 &= \{ z : 0 < \text{Im} z < \alpha, \text{Im} z < \text{Re} z - z^* \}, \\
\Omega_2 &= \{ z : 0 < \text{Im} z < \alpha, \text{Im} z < -\text{Re} z + z^* \}, \\
\Omega_3 &= \{ z : 0 < \text{Im} z < \alpha, \text{Im} z < -\text{Re} z - z^* \}, \\
\Omega_4 &= \{ z : -\alpha < \text{Im} z < 0, \text{Im} z > -\text{Re} z + z^* \}, \\
\Omega_5 &= \{ z : -\alpha < \text{Im} z < 0, \text{Im} z > \text{Re} z - z^* \}, \\
\Omega_6 &= \{ z : -\alpha < \text{Im} z < 0, \text{Im} z > \text{Re} z + z^* \}.
\end{align*}

(166)

There exists $\alpha > 0$, sufficiently small, so that $L$ has an analytic extension to $\Omega_4 \cup \Omega_6$ and $U$ has an analytic extension to $\Omega_1 \cup \Omega_3$. Similarly, $P_1$ and $M_1$ have analytic extensions to $\Omega_2$ and $\Omega_5$, respectively. So, define

$$\hat{N}_1(z) = N_1(z) \begin{cases}
U(z) & z \in \Omega_1 \cup \Omega_3, \\
P_1(z) & z \in \Omega_2, \\
L(z) & z \in \Omega_4 \cup \Omega_6, \\
M_1(z) & z \in \Omega_5.
\end{cases}$$

(167)

The jump contours and jump matrices for the $\hat{N}_1$ are depicted in figure 7.

We aim to have jumps that are localized at $\pm z^*$, and need to remove the jump on $(-\infty, -z^*) \cup (z^*, \infty)$. Consider the RH problem

$$\Delta^+(s) = \Delta^-(s)D(s), \quad s \in (-\infty, -z^*) \cup (z^*, \infty), \quad \Delta(s) = I + O(s^{-1}) \quad s \to \infty.$$  \hspace{1cm} (168)

This is easily solved via the Cauchy integral

$$\Delta(z) = \text{diag}(\Delta(z), \Delta^{-1}(z)), \quad \log \Delta(z) = \frac{1}{2\pi i} \int_{(-\infty, -z^*) \cup (z^*, \infty)} \frac{\log T(s)}{s - z} \, ds.$$  \hspace{1cm} (169)
Figure 8. The jump contours and jump matrices for the unknown $\hat{N}_1$ defined in (171). The contours are deformed within a strip of width $2\alpha$.

$$\Delta U^{-1}\Delta^{-1} \quad \Delta P_1^{-1}\Delta^{-1} \quad \Delta U^{-1}\Delta^{-1}$$

$$\Delta L\Delta^{-1} \quad \Delta M_1\Delta^{-1} \quad \Delta L\Delta^{-1}$$

$$a \quad a^{-c} \quad a^c$$

$$-z^* \quad z^*$$

$$z_j \quad \Delta S_j$$

$$\Delta S_j^{-1} \quad S_j(z) = \begin{bmatrix} 1 & 0 \\ \frac{c(z_j)}{z-z_j}e^{-2ik\alpha} & 1 \end{bmatrix}$$

Figure 9. A zoomed view of the jump contours and matrices for $\hat{N}_1$. 

$$\Delta U^{-1}\Delta^{-1} \quad \Delta P_1^{-1}\Delta^{-1} \quad \Delta P_1^{-1}\Delta^{-1} \quad \Delta U^{-1}\Delta^{-1}$$

$$\Delta L\Delta^{-1} \quad \Delta M_1\Delta^{-1} \quad \Delta M_1\Delta^{-1} \quad \Delta L\Delta^{-1}$$

$$\Delta U^{-1}\Delta^{-1} \quad \Delta P_1^{-1}\Delta^{-1} \quad \Delta U^{-1}\Delta^{-1}$$

$$\Delta L\Delta^{-1}$$

$$\Delta S_j^{-1}(-\cdot)\Delta^{-1}$$
Now, fix $0 < r < \delta$, and define

$$
\Sigma(z) = \begin{cases} 
\Delta^{-1}(z) & z \notin (-\infty, -z^*) \cup (z^*, \infty), |z \pm z^*| > r, \\
I & |z + z^*| < r, \quad \frac{3\pi}{4} < \arg(z + z^*) < \pi, \\
D(z) & |z + z^*| < r, \quad -\pi < \arg(z + z^*) < -3\pi/4, \\
L(z)D(z) & |z + z^*| < r, \quad -\frac{3\pi}{4} < \arg(z + z^*) < -\frac{\pi}{4}, \\
P(z)U^{-1}(z) & |z + z^*| < r, \quad -\frac{\pi}{4} < \arg(z + z^*) < \frac{3\pi}{4}, \\
U^{-1}(z) & |z + z^*| < r, \quad \frac{4}{\pi} < \arg(z + z^*) < \frac{3\pi}{4}, \quad (170) \\
D(z) & |z - z^*| < r, \quad -\frac{\pi}{4} < \arg(z - z^*) < 0, \\
L(z)D(z) & |z - z^*| < r, \quad -\frac{3\pi}{4} < \arg(z - z^*) < -\frac{\pi}{4}, \\
P(z)U^{-1}(z) & |z - z^*| < r, \quad -\pi < \arg(z - z^*) < -\frac{3\pi}{4}, \\
U^{-1}(z) & |z - z^*| < r, \quad \frac{3\pi}{4} < \arg(z - z^*) < \pi, \\
\end{cases}
$$

From this we define

$$
\hat{N}_1(z) = \bar{N}_1(z) \Sigma(z). \quad (171)
$$

The jump contours and jump matrices for $\hat{N}_1(z)$ are displayed in figure 8 with a zoomed view given in figure 9. Before this RH problem is discretized and solved, the transformation discussed in section 5.3 is performed.

This deformation, following the arguments in [39], give accurate computations for all $(x,t)$ such that $z^* \geq c + \delta$, even as $t \to \infty$. As $t$ increases, one has to vary $r$ and $r \sim t^{-1/2}$ is seen to be an acceptable choice [40].

**Remark 6.1.** For a solution without solitons it follows directly from our deformation of RH problem 4 that as $x$ increases for $x \geq -2c^2t$, $N_2 \to \begin{bmatrix} 1 & 1 \end{bmatrix}$ exponentially. Furthermore, if $\sqrt{\frac{x^2}{t}} \geq c + \delta$ as $t \to \infty$ the standard asymptotic analysis for the dispersive tail of the KdV equation applies [15]. This implies that neither of these regions contain a dispersive shock wave and the so-called dispersive shock wave region must be contained within

$$
-12c^2t \leq x \leq -2c^2t.
$$

If we instead consider initial data $q(x)$ with $\lim_{x \to -\infty} q(x) = c^2$ and $\lim_{x \to +\infty} q(x) = 0$ we apply the Galilean boost to find the region

$$
-6c^2 \leq x \leq 4c^2t.
$$

We can recover the results of [16] for the leading and trailing edges of the shock wave region by setting $c^2 = 1/6$ (i.e. $-t \leq x \leq \frac{3}{2}t$).

**Remark 6.2.** We can also examine soliton amplitudes and velocities using our formulation. A soliton of amplitude $\eta > 0$ on a background of height $h \in \mathbb{R}$ has velocity $v = 2\eta + 6h$. The soliton speed for $x \ll h$ corresponding to a zero $z_j = i\alpha$ can be determined from the exponent in the residue conditions for $N_1$ (RH problem 3):

$$
-2iz_jx - 8iz_j^2t = -2i(ia)x - 8i(ia)^3t = 2\alpha(x - 4a^2t).
$$

And the velocity is $4a^2$ on a zero background—the amplitude is $2a^2$. Then for $x \gg 0$ we examine the exponent in the residue conditions for $N_2$ (RH Problem 4):
\[ 2i\lambda(z_j)x + 8i\varphi(z_j)t = 2i\lambda(ix)(x - 4a^2t + 2c^2t). \]

The velocity is \( 4a^2 - 2c^2 \) on a background of height \(-c^2\)—the amplitude is \( 2a^2 + 2c^2 \). Therefore the amplitude of a soliton that passes through a dispersive shock wave of offset height \( c^2 \) is increased by \( 2c^2 \).

**Remark 6.3.** Another important consequence is that all solitons to the right of a dispersive shock wave move with a velocity that greater than \(-2c^2\) (the velocity of the dispersive shock wave itself). This indicates that if one chooses \( q(x) \approx c^2 + H_c(x) + \text{sech}^2(\sqrt{A/2}(x - x_0)) \) for \( x_0 \gg 1 \) and \( 0 < A < 2c^2 \), where the dispersive shock wave moves with velocity \( 4c^2 \), no soliton is produced by the evolution. This \( \text{sech}^2 \) profile evolves in a similar fashion to a solitary wave for intermediate time scales at a speed that is less than the shock wave and is eventually absorbed. Numerical experiments indicate that this manifests itself as a region where the reflection coefficient is large due to \( a(z) \) being small but non-vanishing for \( z \in (-c, c) \). Recall that \( a(z) \) may not vanish on the real axis (see section 3.6). This scenario is in agreement with so-called ‘pseudo-embedded eigenvalues’ observed for ‘trapped solitons’ in the case of rarefaction in [1].

### 7. Numerical examples

Combining the two deformations discussed in the previous section, numerical computations will be accurate asymptotically\(^7\) for

\[ x \leq -12(c + \delta)^2 \quad \text{and} \quad -2c^2t \leq x. \]  \hspace{1cm} (172)

This leaves a rather large sector of the \((x, t)\) plane unaccounted for. A future work will focus on properly filling this gap.

Nevertheless, we can compute the entire solution profile for a restricted interval of \( t \) values, provided that \( c \) is not too large. To accomplish this, we made an ad hoc modification of \( z^* \):

\[ z_m^* = \max\{z^*, c + \delta\}, \]  \hspace{1cm} (173)

where, in practice we set \( \delta = 1/10 \). And then we use the deformation and RH problem displayed in figure 8 for \( x < -2c^2t \) with \( z^* \) replaced with \( z_m^* \) and the deformation and RH problem displayed in figure 5 for \( x \geq -2c^2t \).

The initial data \( u(x, 0) \) in our examples satisfies

\[ u(x, 0) \rightarrow c^2, \quad x \rightarrow -\infty \quad \text{and} \quad u(x, 0) \rightarrow 0, \quad x \rightarrow +\infty. \]  \hspace{1cm} (174)

It is simple to use the Galilean boost to map such a solution to one satisfying (5), see remark 1.1.

**Remark 7.1.** Evaluating \( u(x, t) \) for small \( t \) can be difficult if \( R_l(z) \) and \( R_r(z) \) do not decay quickly as \( z \rightarrow \pm \infty \). This issue is analogous to computing the Fourier transform of a function that decays slowly at infinity — one cannot truncate the domain of integration enough to allow for the capturing of oscillation. But for \( t > 0 \), the deformations outlined in the previous section induce exponential decay, alleviating this issue to an extent. Indeed, as \( t \downarrow 0 \) the ad-

\(^7\)This means that computations will be accurate for all \( x \) and \( t \) in these regions including both large and small values.
Additional decay is reduced.

For infinitely smooth initial data \( u(x,0) \), from lemma 3.10, this is not an issue even as \( t \) approaches zero. So, we are able to evaluate the solution profile for all \( x \) and \( t \in [0, T] \). In our computations \( T \approx 1 \).

For discontinuous initial data \( u(x,0) \), \( t \downarrow 0 \) is a singular limit and the deformations described only allow for the computation for all \( x \) but \( t \in [\epsilon, T] \), \( \epsilon > 0 \), see figure 10.

7.1. \( u_0 = 0 \)

When \( u_0 = 0 \), the functions \( A, B, a \) and \( b \) can be determined explicitly.

---

**Figure 10.** The solution of the KdV equation at \( t = 1 \) when \( u(x,0) = H_c(x) + c^2 \), \( c = 1 \) (top), \( c = \sqrt{2} \) (middle) and \( c = \sqrt{3} \) (bottom). The gray curve indicates the initial condition.
\[ A(z) = \frac{1}{2} \left( 1 + \frac{z}{\lambda(z)} \right), \quad B(z) = \frac{1}{2} \left( 1 - \frac{z}{\lambda(z)} \right) \]
\[ a(z) = \frac{z + \lambda(z)}{2z}, \quad b(z) = \frac{z - \lambda(z)}{2z}. \]

We display the solution of (1) with \( u(x, 0) = H_{c}(x) + c^2 \) for various values of \( c \), all evaluated at \( t = 1 \).

7.2. Smooth soliton-free data

An example of smooth data that fits into the described framework is
\[ u(x, 0) = -\frac{1}{4} \left( 1 + \text{erf}(x) \right)^2, \tag{176} \]
where \( \text{erf}(x) \) is the error function [29]. In this case, computing \( R_r \) and \( R_l \) is non-trivial. We display these functions in figures 11(a) and (b), noting that the decay of \( u_0 \) makes \( A, B, a \) and \( b \) analytic functions of \( z \) for all \( z \) off the cut \([−c, c]\). The corresponding solution is given in figure 12.

7.3. Smooth data with a soliton

An example of smooth data that fits into the described framework but produces a soliton is
\[ u(x, 0) = -\frac{1}{4} \left( 1 + \text{erf}(x) \right)^2 + 2e^{-x^2/2}. \tag{177} \]
The reflection coefficients are given in figures 13(a) and (b). The data associated to the pole in the RH problem is given by
The speed of the soliton can be easily read off from the RH problem. For example, the jump on $\Sigma_j$ in RH problem 3 is determined by

$$e^{-2iz_jx-8iz_j^2t} = e^{-2iz_j(x+4z_j^2t)}.$$  

This indicates a velocity of $-4z_j^2$ for $x \ll 0$, in the case of data decaying to 0 at $-\infty$ and tending to $-c^2$ at $+\infty$. In the current setting, this gives a velocity of $-4z_j^2 + 6c^2$. Similarly, for

$$z_1 \approx 0.950681i,$$

$$c(z_1) \approx 3.481191i,$$

$$C(z_1) \approx 3.903511i.$$  

The corresponding solution is displayed in figure 14.

**Remark 7.2 (Soliton speed).** The speed of the soliton can be easily read off from the RH problem. For example, the jump on $\Sigma_j$ in RH problem 3 is determined by

$$e^{-2iz_jx-8iz_j^2t} = e^{-2iz_j(x+4z_j^2t)}.$$  

This indicates a velocity of $-4z_j^2$ for $x \ll 0$, in the case of data decaying to 0 at $-\infty$ and tending to $-c^2$ at $+\infty$. In the current setting, this gives a velocity of $-4z_j^2 + 6c^2$. Similarly, for

$$z_1 \approx 0.950681i,$$

$$c(z_1) \approx 3.481191i,$$

$$C(z_1) \approx 3.903511i.$$  

The corresponding solution is displayed in figure 14.
we consider the exponential in the jump on $\Sigma_j$ in RH problem 4
\[
e^{2i\lambda(z_j)x+8i\lambda(z_j)t+12i\lambda^2(z_j)t} = e^{2i\lambda(z_j)(x+6e^2t+4(z_j^2-c^2)t)}.
\] (180)

This indicates a velocity of $-4z_j^2 - 2c^2$, in the case of data decaying to 0 at $-\infty$ and tending to $-c^2$ at $+\infty$. For the current setting of (177), the velocity is $-4z_j^2 + 4c^2$, a decrease in velocity of $2c^2$.

7.4. Validation and comparison with time-stepping routines

In this section we first demonstrate that the numerical IST has accuracy advantages over traditional time-stepping routines. We then demonstrate that our approach converges exponentially with respect to the number of collocation points used.

7.4.1. Periodic approximation and time-stepping. We describe a well-known numerical method for the KdV equation and use it to confirm the accuracy of our numerical inverse scattering transform. Consider the initial-value problem for $L > 0$
\[
p_t + 6pp_x + p_{xxx} = 0,
p(x, 0; L) = q(x)\psi_L(x), \quad x \in [-L, L),
p(x, t; L) = p(x + 2L, t; L).
\] (181)

Recall that $q$ is the initial data for the initial-value problem (1). Here $\psi_L$ is a $C^\infty$ function with support in $(-L, L)$ and $\psi_L(x) = 1$ for $x \in [-L + \delta, L - \delta]$, $\delta > 0$. As $L \to \infty$, we expect $p(x, t; L) \to u(x, t)$. To examine this, we solve (181) using an exponential integrator which we now derive. General references for this are [17, 20, 21]. Let $\mathcal{F}$ denote the Fourier transform
\[
a = \mathcal{F}u, \quad u \in L^1([-L, L]), \quad a_j = \frac{1}{2L} \int_{-L}^{L} e^{-\pi ijx/L} u(x) \, dx.
\]

Define
\[
a(t) = \mathcal{F}u(\cdot, t).
\]

Figure 13. The right and left reflection coefficients for the smooth initial data (177) that gives rise to a soliton: $u(x, 0) = -\frac{1}{2}(1 + \text{erf}(x))^2 + 2e^{-x^2/2}$. (a) The real (solid) and imaginary (dashed) parts of $R_l(z)$ when $u(x, 0)$ is given in (177). (b) The real (solid) and imaginary (dashed) parts of $R_r(z)$ when $u(x, 0)$ is given in (177).
We define two operators $\mathcal{S}_T$ and $\mathcal{D}$ by
\[
(\mathcal{S}_T a)_j = e^{i \left( \frac{\pi j}{L} \right)^3} a_j, \quad (\mathcal{D} a)_j = i \left( \frac{\pi j}{L} \right) a_j.
\]
Then set $\dot{\mathbf{a}}(t) = \mathcal{S}_{-1} \mathbf{a}(t)$. We look for the equation satisfied by $\dot{\mathbf{a}}(t)$:
\[
\frac{d}{dt} \dot{\mathbf{a}}(t) = \mathcal{S}_{-1} \left( \frac{d}{dt} \mathbf{a}(t) + \mathcal{D}^3 \mathbf{a}(t) \right) = -6 \mathcal{S}_{-1} \mathcal{F} \left( (\mathcal{F}^{-1} \mathcal{D}) (\mathcal{F}^{-1} \mathbf{a}) \right) = -3 \mathcal{S}_{-1} \mathcal{D} \mathcal{F} \left( (\mathcal{F}^{-1} \mathcal{S}_1 \dot{\mathbf{a}})^2 \right) =: F(\dot{\mathbf{a}}(t), t).
\]

This gives a bi-infinite system of non-autonomous nonlinear ordinary differential equations (ODEs). If we replace $\mathcal{F}$ with the discrete (or fast) Fourier transform (FFT), the system

Figure 14. The solution of the KdV equation at $t = 1, 2, 3$ when $u(x, 0)$ is the smooth initial data (177) that gives rise to a soliton: $u(x, 0) = -\frac{1}{2} (1 + \text{erf}(x))^2 + 2 e^{-x^2/2}$. The gray curve indicates the initial condition.
becomes simply a finite system of non-autonomous ODEs and we use the fourth-order Runge–Kutta scheme to integrate this system. We use a time step of $\Delta t = 0.00005$ to force the local truncation error to be on the order of machine precision. We use $n = 2^{12}$ coefficients in the FFT which ensures that the highest-order coefficients decay to be on the order of machine precision in all computations. Lastly, we use

$$\psi_L(x) = \frac{1}{4} \left( 1 + \tanh(x + L/2) \right) \left( 1 - \tanh(x - L/2) \right).$$

While this function does not have its support within $(-L, L)$, it differs from one that does by less than numerical underflow if, for example, $L \geq 100$.

In figure 15 we display the numerically computed difference $|u(x, t) - p(x, t; L)|$ when $q(x) = 1 - \frac{1}{2} (1 + \text{erf}(x))^2$ for $L = 100, 200, 300, 400$. The figure indicates that the errors decay exponentially as $L$ increases. This is indicative of the fact that the errors in the numerical computation of both $u(x, t)$ and $p(x, t; L)$ is much smaller than the actual difference $|u(x, t) - p(x, t; L)|$. But, one also sees that there is significant grown in errors from $t = 1$ to $t = 2$. The high velocity of the dispersive tail for $x < 0$ prevents $p(x, t; L)$ being a good approximation of $u(x, t)$ as $t$ increases.

7.5. Convergence rate of the numerical approximation of the IST

To demonstrate the convergence of the approximation of the solution of the KdV equation we perform the following experiment. In considering the assumption (148) we divide the contours $\{\Gamma_{\ell}\}$ into two categories. If $\Gamma_{\ell}$ is in the first category, we set $m_{\ell}(n) = n$ in (149). If $\Gamma_{\ell}$ is in the second category, we set $m_{\ell}(n) = 3n$. This allows us to use more collocation points on contours where we expect the solution of the singular integral equation to have larger derivatives. Recall that the convergence of the method is tied to the size of the derivatives of the

![Figure 15. The numerically computed difference $|u(x, t) - p(x, t; L)|$ when the initial condition is given by $q(x) = 1 - \frac{1}{2} (1 + \text{erf}(x))^2$ for $L = 100, 200, 300, 400$. The periodic approximation improves as $L$ increases. Additionally, this validates the accuracy of the numerical computation of the inverse scattering transform. The figure is given on a log scale and from this one can see that the error decreases approximately exponentially with respect to $L$. From the asymptotic formula for the solution (see [9], for example) one can predict that the errors, for fixed $L$, should increase exponentially in $t$. In the lower panel, one sees the significant increase in errors as $t$ increases.](image-url)
Then we fix $N > 2$ and compute the solution of the KdV equation by solving for $n = 2, 3, \ldots, N$ and compare it to the solution computed with $n = 2N$. We call this the Cauchy error. We do this with $u(x, 0) = -\frac{1}{4} (1 + \text{erf}(x))^2$ for two different values of $(x, t)$ and give the errors in figure 16 on a log scale. The (approximately) constant slope in these plots indicates (approximately) exponential convergence with respect to $n$.

As an additional check on the behavior of the errors of our numerical method, we look beyond the region where time-stepping methods are applicable, again using the notion of Cauchy error. We choose two rays in the $(x, t)$-plane: $(x, t) = (-14t, t)$ (were the deformation depicted in figure 8 is applicable) and $(x, t) = (t, t)$ (where the deformation depicted in figure 5 is applicable). We choose to look along rays because that allows the same deformation to be used for all $t > 0$. The Cauchy error remains small, see figure 17. Note that the solution

---

---

Figure 16. A demonstration that the convergence rate of the proposed numerical method of the KdV equation is almost exponential by examining the Cauchy error plotted on a log scale. Left panel: the convergence to the solution at $(x, t) = (-16, 1)$ with $N = 24$. This is the evaluation of the solution using the deformation depicted in figure 8. Right panel: the convergence to the solution at $(x, t) = (4, 1)$ with $N = 40$. This is the evaluation of the solution using the deformation depicted in figure 5.

Figure 17. A demonstration that the error of the proposed numerical method for the KdV equation remains small along certain rays in the $(x, t)$-plane. Left panel: the difference of the approximate solution with $N = 20$ along the ray $(-14t, t)$ as $t$ increases beyond $10^4$. This is the evaluation of the solution using the deformation depicted in figure 8. Right panel: the Cauchy error with $N = 20$ along the ray $(t, t)$ as $t$ increases beyond $10^4$. This is the evaluation of the solution using the deformation depicted in figure 5.

---

---

8 Note that the linear system (150) is of dimension $\sum_{\ell=1}^S m_\ell(n)$. 
tends exponentially to $-c^2$ along this the ray $(x,t) = (t,t)$ and the solution method captures this, giving good relative accuracy.

**Acknowledgments**

The authors would like to thank Percy Deift, Mark Hoefer, and Peter Miller for their input on this work. This work was supported in part by an AMS-Simons Travel Grant (DB) and by NSF DMS-1753185, DMS-1945651 (TT).

**Appendix A. Solitons and time-dependence**

We derive time dependence of the scattering data under the assumption that $u_0(\cdot,t) = u(\cdot,t) - H_c(\cdot)$ and its $x$ derivative decay rapidly at infinity for all $t$. After the time dependence is determined, one can appeal to the so-called dressing method to show that if the solution of the RH problem exists and is unique, then it produces a solution of the KdV equation (see [39, proposition 12.1], for example).

We have defined the (partial) scattering map $S_{u_0} = (R_l, R_r)$. Define $R_t(z; t)$ and $R_l(z; t)$ by the mapping

$$S(u(\cdot,t) - H_c) = (R_l(\cdot; t), R_r(\cdot; t))$$

where $u(x,t)$ is the solution of the KdV equation with initial data $u_0 + H_c$. The map gives only the partial scattering data because we have not yet incorporated discrete spectrum, i.e. solitons. Define $a(z; t), b(z; t), A(z; t)$ and $B(z; t)$ to be the functions corresponding to $u(\cdot, t) - H_c$.

Extend the solutions $\phi^{p,m}(z; x)$ and $\psi^{p,m}(z; x)$ to functions $\phi^{p,m}(z; x, t)$ and $\psi^{p,m}(z; x, t)$ by replacing $u_0(x)$ with $u(x, t)$. These functions satisfy the following scattering and evolution equations (scalar Lax pair):

$$-\phi_{xx} - u(x,t)\phi = z^2\phi, \quad \phi_t = (4z^2 - 2u(x,t))\phi_x + (u_x(x,t) + 1)\phi. \quad (A.2)$$

The compatibility condition $\phi_{xt} = \phi_{tx}$ with the condition $z_t = 0$ gives the KdV equation (1).

Consider, now with time dependence, for $z \in \mathbb{R}$,

$$\psi^p(z; x, t) = a(z; t)\phi^p(z; x, t) + b(z; t)\phi^m(z; x, t), \quad \phi^m(z; x, t) = B(z; t)\psi^p(z; x, t) + A(z; t)\psi^m(z; x, t). \quad (A.3)$$

So, for $t$ and $z > c^2$ fixed, we have

$$a_t(z; t)\phi^p + a(z; t)\phi^p + b_t(z; t)\phi^m + b(z; t)\phi^m = (4z^2 - 2u(x,t))a(z; t)\phi^p + (4z^2 - 2u(x,t))b(z; t)\phi^m + (u_x(x,t) + 1)(a(z; t)\phi^p + b(z; t)\phi^m). \quad (A.4)$$

Then as $x \to -\infty$,

$$\phi^p(z; x, t) = i z \phi^p(z; x, t)(1 + o(1)), \quad \phi^m(z; x, t) = -iz \phi^m(z; x, t)(1 + o(1)). \quad (A.5)$$

Using that $u(x, t), u_x(x, t) \to 0$ as $x \to -\infty$, we find

$$a_t(z; t) - 4iz^2 a(z; t)\phi^p + (b_t(z; t) + 4iz^2 b(z; t))\phi^m = o(1), \quad x \to -\infty. \quad (A.6)$$
This implies that
\[ a(z; t) = a(z; 0) e^{4iz^4 t}, \quad b(z; t) = b(z; 0) e^{-4iz^4 t} \]  \hspace{1cm} (A.7)
and therefore
\[ R_l(z; t) = R_l(z; 0) e^{-8iz^4 t}. \]  \hspace{1cm} (A.8)
This also holds for \(-c \leq z \leq c\). Now, consider
\[
B_l(z; t)\psi^R + B(z; t)\psi^P + A_l(z; t)\psi^m + A(z; t)\psi^m
= (4z^2 - 2u(x, t))B(z; t)\psi^P + (4z^2 - 2u(x, t))A(z; t)\psi^m + (u_t(x, t) + 1)(B(z; t)\psi^P + A(z; t)\psi^m)
\]  \hspace{1cm} (A.9)
and then as \(x \to +\infty,
\[
\psi^R(z; x, t) = i\lambda(z)\psi^R(z; x, t)(1 + o(1)), \quad \psi^m(x; z, t) = -i\lambda(z)\psi^m(x; z, t)(1 + o(1)), \]  \hspace{1cm} (A.10)
and \(u(x, t) \to -c^2, u_t(x, t) \to 0\). Therefore as \(x \to +\infty\)
\[
(B_l(z; t) - i\lambda(z)(4z^2 + 2c^2)B(z; t))\psi^R + (A_l(z; t) + i\lambda(z)(4z^2 + 2c^2)A(z; t))\psi^m = o(1). \]  \hspace{1cm} (A.11)
Therefore,
\[
B(z; t) = B(z; 0) e^{4i\lambda^3(t) + 6i\Delta^2\lambda(x) t}, \quad A(z; t) = A(z; 0) e^{-4i\lambda^3(t) + 6i\Delta^2\lambda(x) t}. \]  \hspace{1cm} (A.12)
This then gives for \(c^2 > s^2\)
\[
R_l(z; t) = R_l(z; 0) e^{8i\lambda^3(t) + 6i\Delta^2\lambda(x) t}, \]  \hspace{1cm} (A.13)
and \(R_l(x; t) = R_l(x; 0) e^{8i\lambda^3(t) + 6i\Delta^2\lambda(x) t}\) for \(-c \leq s \leq c\).

Next, assume \(a(z) = o(z; 0)\) (and hence \(A(z)\) has a simple zero at \(z = z'\)). We then must incorporate a residue condition because \(N_1\) and \(N_2\) will no longer be analytic for \(z \not\in \mathbb{R}\). So, consider
\[
\text{Res}_{z = z'} N_1(z) = \text{Res}_{z = z'} L_1(z) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} e^{-iz\sigma_0} = \begin{bmatrix} \text{Res}_{z = z'} \frac{\psi^R(z, x)}{\sigma_0(z)} e^{-iz\sigma_0} & 0 \\ 0 & 0 \end{bmatrix} \]  \hspace{1cm} (A.14)
because the second entry is analytic at \(z = z'\). Then the fact that \(a(z'x, t) = 0\) implies that there exists \(b_{z'}(t) \in \mathbb{C}\) such that
\[
\psi^R(z'x, t) = b_{z'}(t)\psi^R(z'; x, t), \quad b_{z'}(t) = b_{z'}(0) e^{-4iz'^4 t} \]  \hspace{1cm} (A.15)
and therefore
\[
\frac{\psi^R(z', x, t)}{\sigma_0(z')} e^{-iz\sigma_0} = \begin{bmatrix} \psi^m(z', x, t) b_{z'}(0) \sigma_0(z') e^{-iz'\sigma_0^2 t} & 0 \\ 0 & 0 \end{bmatrix} = \lim_{z \to z'} \begin{bmatrix} 0 & b_{z'}(0) \sigma_0(z') e^{-iz'\sigma_0^2 t} \\ b_{z'}(0) \sigma_0(z') e^{-iz'\sigma_0^2 t} & 0 \end{bmatrix}. \]  \hspace{1cm} (A.16)
Similarly, at \(z = -z'\)
\[
\text{Res}_{z = -z'} N_1(z) = \text{Res}_{z = -z'} N_1(-z) \sigma_1 = \lim_{z \to -z'} \text{Res}_{z = -z'} N_1(-z) \sigma_1 = \lim_{z \to -z'}(-z + z')N_1(z) \sigma_1
\]
\[
= -\lim_{z \to -z'} \begin{bmatrix} 0 & b_{z'}(0) \sigma_0(z') e^{-iz'\sigma_0^2 t} \\ b_{z'}(0) \sigma_0(z') e^{-iz'\sigma_0^2 t} & 0 \end{bmatrix} \sigma_1 = -\lim_{z \to -z'} N_1(z) \sigma_1 \begin{bmatrix} 0 & 0 \\ -b_{z'}(0) \sigma_0(z') e^{-iz'\sigma_0^2 t} & 0 \end{bmatrix} \sigma_1. \]  \hspace{1cm} (A.17)
Completing the analogous calculation for $N_2(z)$, we find

\[
\text{Res}_{z=z'} N_2(z) = \text{Res}_{z=z'} L_2(z) \left[ \begin{array}{c} 1 & 0 \\ 0 & 1/A(z) \end{array} \right] e^{i\lambda(z)x} = \left[ \text{Res}_{z=z'} \frac{\theta^\prime(z)A(z)}{A'(z)} e^{i\lambda(z)x} \right] \left[ \begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \end{array} \right]
\]

\[
= \left[ \frac{\theta^\prime(z)A(z)}{A'(z)} e^{i\lambda(z)x} \lambda(z) \right]
\]

\[
= \lim_{z \to z'} N_2(z) \left[ \begin{array}{c} 0 \\ 0 \end{array} \right] e^{2i\lambda(z')x} + 8i\lambda(z') + 12i^2\lambda(z') \mu \left[ \begin{array}{c} 0 \\ 0 \end{array} \right]
\]

(A.18)

and

\[
\text{Res}_{z=z'} N_2(z) = \lim_{z \to z'} N_2(z) \sigma_1 \left[ \begin{array}{c} 0 \\ 0 \end{array} \right] e^{2i\lambda(z')x} + 8i\lambda(z') + 12i^2\lambda(z') \mu \left[ \begin{array}{c} 0 \\ 0 \end{array} \right]
\]

For such a value of $z'$, define

\[
c(z') = \frac{b(z')}{d(z')}, \quad C(z') = \frac{1}{b(z') A(z')}
\]

(A.20)

A.1. From residues to jumps

It will be inconvenient in what follows for us to treat residue conditions directly. So, we deform them to jump conditions on small circles. Assume $N(z)$ is a vector-valued analytic function in a open neighborhood of $z'$ that satisfies

\[
\text{Res}_{z=z'} N(z) = \lim_{z \to z'} N(z) \left[ \begin{array}{c} 0 \\ -\alpha \\ 0 \end{array} \right], \quad \alpha \in \mathbb{C}.
\]

(A.21)

Choose $\epsilon > 0$ small enough so that $\{ |z - z'| = \epsilon \} \subset U$ and define

\[
M(z) = \left\{ \begin{array}{ll}
N(z) & \text{if } |z - z'| < \epsilon, \\
N(z) & \text{otherwise.}
\end{array} \right.
\]

(A.22)

Then it follows that $M$ is analytic in $U \setminus \{ |z - z'| = \epsilon \}$ and if $\{ |z - z'| = \epsilon \}$ is given a clockwise orientation, then

\[
M^+(s) = M^-(s) \left[ \begin{array}{c} e^{i\alpha} \\ 1 \\ e^{i\alpha} \\ 1 \end{array} \right], \quad |s - z'| = \epsilon.
\]

In such a way, residue conditions are equivalent to rational jump conditions.

Appendix B. Unique solvability of the Riemann–Hilbert problems

B.1. Unique solvability of RH problem 3

Before proving theorem 3.14 we establish some elementary facts.

**Lemma B.1.** Assume $\Gamma$ is an admissible contour that satisfies $\Gamma = \bar{\Gamma}$, with a reversal of orientation. Then $F(z) = \begin{bmatrix} F_1(z) & F_2(z) \end{bmatrix}$, where $F_1, F_2 \in L^2_+(\Gamma)$ satisfies

\[
F(-z) = F(z) \sigma_1, \quad z \in \mathbb{C} \setminus \Gamma
\]

(B.1)
if and only if $F(z) = C_\Gamma f(z)$ for some $f \in L^2(\Gamma)$ (componentwise) satisfying
\[ -f(-s) = f(s)\sigma_1, \quad s \in \Gamma. \] (B.2)

**Proof.** Assume $f \in L^2(\Gamma)$ satisfies (B.2). And consider, for $z \not\in \Gamma$,
\[ F(z) = \frac{1}{2\pi i} \int_{\Gamma} f(s) \, ds = \frac{1}{2\pi i} \int_{-\Gamma} f(-s) \, ds = \frac{1}{2\pi i} \int_{\Gamma} f(s) \sigma_1 \, ds = F(-z)\sigma_1. \] (B.3)

Conversely, we have that $F = C_\Gamma f$ for some $f \in L^2(\Gamma)$ and if $F$ satisfies (B.1) then for all $z \in \mathbb{C} \setminus \Gamma$
\[ 0 = \frac{1}{2\pi i} \int_{\Gamma} (f(s) + f(-s)\sigma_1) \frac{ds}{s-z}. \] (B.4)
Because $C_\Gamma^+ f(s) - C_\Gamma^- f(s) = f(s)$ for a.e. $s \in \Gamma$, we find that (B.2) holds. □

**Definition B.2.** If $\Gamma$ is admissible, define
\[ L^2_\pm(\Gamma) = L^2_\pm \Gamma^2(\Gamma) = \left\{ f = [f_1 \ f_2], \ f_1, f_2 \in L^2(\Gamma), \ f(s) = -f(-s)\sigma_1 \right\}, \]
\[ L^2_{\pm-s}(\Gamma) = \left\{ f = [f_1 \ f_2], \ f_1, f_2 \in L^2(\Gamma), \ f(s) = f(s)\sigma_1 \right\}. \] (B.5)

**Lemma B.3.** If $\Gamma$ is admissible then
\[ L^2(\Gamma) = L^2_\pm(\Gamma) \oplus L^2_{\pm-s}(\Gamma). \] (B.6)

**Proof.** For $u \in L^2(\Gamma)$ define
\[ P u(s) = \frac{1}{2} (u(s) - u(-s)\sigma_1). \] (B.7)
Then $P$ is a projection onto $L^2_\pm(\Gamma)$. It also follows that $\mathcal{I} - P$ maps $L^2(\Gamma)$ onto $L^2_{\pm-s}(\Gamma)$. □

**Lemma B.4.** Suppose $\Gamma$ is admissible.

- If $u \in L^2_{\pm-s}(\Gamma)$ then
\[ C_\Gamma^- u(-s)\sigma_1 = \pm C_\Gamma^+ u(s), \] (B.8)
and therefore
\[ C_\Gamma^+ u(-s)\sigma_1 = \pm C_\Gamma^- u(s). \] (B.9)

- If $M, P : \Gamma \to \mathbb{C}^{2 \times 2}$, $M, P \in L^\infty(\Gamma)$ satisfy
\[ M(s) = \sigma_1 P(-s)\sigma_1 \] (B.10)
then the operator
\[ u \mapsto C_\Gamma^+ u \cdot P - C_\Gamma^- u \cdot M = u - C_\Gamma^- u \cdot (P - M) \] (B.11)
Proof. The calculation above implies the first part. Let \( u \in L^2(\Gamma) \). Then the second part follows from
\[
C_+^+ u(-s)P(-s)\sigma_1 - C_+^- u(-s)M(-s)\sigma_1 = C_+^+ u(-s)\sigma_1 M(s) - C_+^- u(-s)\sigma_1 P(s) \\
= \pm (C_+^+ u(s)M(s) - C_+^- u(s)P(s)) = \mp (C_+^+ u(s)P(s) - C_+^- u(s)M(s)). 
\]
(B.12) \( \square \)

Theorem B.5. Suppose \( \Gamma \) is admissible and \( M, P : \Gamma \to \mathbb{C}^{2 \times 2} \), \( M, P \in L^\infty(\Gamma) \) satisfy (B.10). Further, suppose the operator
\[
u \mapsto C \nu := u - C_+^- u \cdot (P - M) 
\]
is invertible on \( L^2(\Gamma) \). Then \( C_{\vert L^2(\Gamma)} \) is invertible on \( L^2(\Gamma) \).

Proof. It suffices to show that if \( C \nu = f \) where \( f \in L^2(\Gamma) \) then \( u \in L^2(\Gamma) \). Suppose \( u = v_+ + v_- \) where \( v_+ \in L^2(\Gamma) \), and \( v_- \neq 0 \). Then \( C v_- \in L^2(\Gamma) \), and \( C v_- \neq 0 \). But this contradicts that \( f \in L^2(\Gamma) \)
\( \square \)

So, we find that any \( L^2 \) solution \( N_1 \) of RH problem 3 must satisfy \( N_1 = C_+ u \) for some \( u \in L^2(\Gamma) \) and
\[
u(s) - C_+^- u(s) \cdot (J_1(s) - I) = \begin{bmatrix} 1 & 1 \end{bmatrix} \cdot (J_1(s) - I), \\
J_1(s) = \begin{bmatrix} 1 - |R_1(s)|^2 & -R_1(s) e^{2i\pi + 8i\pi} \\
R_1(s) e^{-2i\pi - 8i\pi} & 1 \end{bmatrix} \quad s \in \mathbb{R}, \\
\begin{bmatrix} 1 \ & -\frac{r(s) e^{-2i\pi + 8i\pi}}{s} \\
\frac{r(s) e^{-2i\pi - 8i\pi}}{s} & 1 \end{bmatrix} \quad s \in \Sigma_j, \\
\begin{bmatrix} 1 & -\frac{r(s) e^{-2i\pi + 8i\pi}}{s} \\
0 & 1 \end{bmatrix} \quad s \in -\Sigma. 
\]
We note that the operator \( u \mapsto u - C_+^- u \cdot (J_1 - I) \) does not map \( L^2(\Gamma) \) to itself. So, we need to decompose \( J_1 \) first. Write
\[
J_1(s) = M_1(s) P_1^{-1}(s) = \begin{bmatrix} 1 & -R_1(s) e^{2i\pi + 8i\pi} \\
0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\
R_1(s) e^{-2i\pi - 8i\pi} & 1 \end{bmatrix}, \quad s \in \mathbb{R}, \\
J_1(s) = P_1^{-1}(s), \quad M_1(s) = I, \quad s \in \Sigma_j, \\
J_1(s) = M_1(s), \quad P_1(s) = I, \quad s \in -\Sigma_j. 
\]

Lemma B.6. The operator
\[
u \mapsto u \cdot P_1 - C_+^- u \cdot (M_1 - P_1) 
\]
is bounded on \( L^2(\Gamma) \) to itself and if \( R_1 \in L^2(\mathbb{R}) \) then
\[
\begin{bmatrix} 1 & 1 \end{bmatrix} \cdot (M_1(\cdot) - P_1(\cdot)) \in L^2(\Gamma). 
\]
(B.17)
Proof. It follows that
\[ \sigma_1 M_1(-s) \sigma_1 = P_1(s). \] \hfill (B.18)

Then from lemma B.4 the lemma follows.
\[ \square \]

Lemma B.7. The operator 
\[ u \mapsto u \cdot P_1 - C_T u \cdot (M_1 - P_1) \] \hfill (B.19)
is Fredholm on \( L^2_\sigma(\Gamma) \) with index zero provided that \( R_1 \) is continuous and decays at infinity.

Proof. The fact that this operator is Fredholm on \( L^2_\sigma(\Gamma) \) follows from standard arguments \[39\]. This implies that the operator is Fredholm on the invariant subspace \( L^2_\sigma(\Gamma) \). Then replace \( R_1 \) with \( \alpha R_1 \) for \( 0 \leq \alpha \leq 1 \). For \( \alpha \) sufficiently small, the operator is invertible and is therefore index zero. It must therefore be index zero for all \( \alpha \).
\[ \square \]

Proof of theorem 3.14. The unique solvability of RH problem 3 is implied by the invertibility of (B.19). And to this end, because the Fredholm index of the operator is zero, it suffices to show that the kernel is trivial. Assume \( u \in L^2_\sigma(\Gamma) \) is an element of the kernel and define 
\[ N(z)^+ = C_R u \in H^2(\Gamma). \] \hfill (B.20)

We use another symmetry of the contour \( \Gamma \). If \( U \) is a connected component of \( \mathbb{C} \setminus \Gamma \) then so is \( \overline{U} := \{ \bar{z} : z \in U \} \). Thus for \( f \in \mathcal{E}^2(U) \), \( f(\bar{\gamma}) \in \mathcal{E}^2(\overline{U}) \) and if \( f \in \mathcal{E}^2(U) \) and \( g \in \mathcal{E}^2(\overline{U}) \) then
\[ \int_{\partial U} f(s) \overline{g(s)} \, ds = 0. \] \hfill (B.21)

We select \( U \) to be the connected component in the upper-half plane that contains the real axis in its boundary. The positively oriented boundary for \( U \) is then the real axis, and \( \cup_j \Sigma_j \) with reversed orientation. Therefore
\[ 0 = \int_R N^+(s) \overline{N^-(s)} \, ds - \sum_j \int_{\Sigma_j} N^-(s) \overline{N^+(s)} \, ds, \] \hfill (B.22)
\[ 0 = \int_R N^-(s) \overline{N^+(s)} \, ds - \sum_j \int_{-\Sigma_j} N^+(s) \overline{N^-(s)} \, ds. \] \hfill (B.23)

Here the second line arises from similar considerations for \( \overline{U} \). Taking orientation into account and using the symmetry of \( N \)
\[ \int_{\Sigma_j} N^-(s) \overline{N^+(s)} \, ds = -\int_{-\Sigma_j} N^-(s) \overline{N^+(s)} \, ds = -\int_{-\Sigma_j} N^+(s) \overline{N^-(s)} \, ds \] \hfill (B.24)

Thus, adding (B.22) and (B.23), we have
\[ 0 = \text{Re} \int_R N^+(s) \overline{N^-(s)} \, ds. \] \hfill (B.25)
We use this to show that $N(z) = 0$ for $z \notin \mathbb{R}$ which implies that $u \equiv 0$. If we set $N(z) = \begin{bmatrix} N_1(z) & N_2(z) \end{bmatrix}$, we find
\[
\int_{\mathbb{R}} N^+(s)N^-(s)^T \, ds = \int_{\mathbb{R}} \left[ |N_1^+(s)|^2 |1 - |R_1(s)|^2| + |N_2^+(s)|^2 \right. \\
\left. + N_2^+(s)N_1^+(s)R_1(-s) e^{2iz+8i\psi(s)} + N_2^+(s)N_1^+(s)R_1(s) e^{-2iz-8i\psi(s)} \right] \, ds.
\]
(B.26)

Taking the real part of this expression, we find
\[
0 = \int_{\mathbb{R}} \left[ |N_1^+(s)|^2 |1 - |R_1(s)|^2| + |N_2^+(s)|^2 \right] \, ds
\]
(B.27)

implying that $N^+(s) = 0$ and therefore $N(z) = 0$, because $|R_1(s)| < 1$ for a.e. $s \in \mathbb{R}$ [19].

\[\square\]

B.2. Unique solvability for RH problem 4

The jump matrix for RH problem 4 is discontinuous and the Fredholm theory no longer applies. We have to perform a lengthy regularization process and then we use the fact that RH problem 3 has a unique solution to show that RH problem 4 has a unique solution. We perform deformations under the assumptions of theorem 3.15. In this section when we refer to assumption (j), we are referring to the $j$th assumption in theorem 3.15. For simplicity we assume $n = 0$, i.e. no solitons. Because all deformations are performed in a neighborhood of the real axis the result immediately applies to the case of $n > 0$.

The remainder of this section constitutes the proof of theorem 3.15

**Proof of theorem 3.15.** From assumptions (1, 4–6, 8, 10), $R_t(s)$ is continuous for $s \in \mathbb{R}$ and satisfies
\[
R_t(s) = L_{-c}(s) + E_{-c}(s), \quad E_{-c}(s) = O(|s + c|), \quad s \to -c,
\]
(B.28)

and $L_{-c}$ has an analytic extension to a neighborhood $\{ |z + c| < \epsilon, \text{Im} \, z > 0 \}$. Note that $R_t(s) = R_t(-s)$ follows from assumptions (2, 3, 7, 9). Then
\[
N_1^+(s) = N_2^+(s)M_2(s)P_2^{-1}(s) = N_2^+(s) \begin{bmatrix} 1 & -R_t(-s) e^{-2i\lambda(s)x-8i\psi(s)t} \\
0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\
0 & 1 \end{bmatrix}.
\]
(B.29)

We factor
\[
M_2(s) = \begin{bmatrix} 1 & -L_{-c}(s) e^{-2i\lambda(s)x-8i\psi(s)t} \\
0 & 1 \end{bmatrix}, \quad E_{-c}(s) = \begin{bmatrix} 1 & -E_{-c}(s) e^{-2i\lambda(s)x-8i\psi(s)t} \\
0 & 1 \end{bmatrix}, \quad R_t(s) = \begin{bmatrix} 1 & 0 \\
0 & 1 \end{bmatrix}.
\]
(B.30)

Then, consider the jump matrix near $s = -c, s > -c$:
\[
N_1^+(s) = N_2^+(s)M_2(s) \begin{bmatrix} 0 & 1 \\
1 & 0 \end{bmatrix} P_2^{-1}(s).
\]
(B.31)
Fix $\epsilon > 0$, and for $z \not\in \mathbb{R} \cup \{z: |z + c| = \epsilon\}$ define

$$N_{2,1}(z) = N_2(z) \begin{cases} I & |z + c| > \epsilon, \\ M_{2,\alpha}(z) & \text{Im} z < 0 \text{ and } |z + c| < \epsilon, \\ P_{2,\alpha}(z) & \text{Im} z > 0 \text{ and } |z + c| < \epsilon. \end{cases} \tag{B.32}$$

Then the sectionally analytic function $N_{2,1}$ has the following jumps when we give the circle $\{s: |s + c| = \epsilon\}$ a clockwise orientation:

$$N_{2,1}^+(s) = N_{2,1}^-(s) \begin{cases} M_2(s)P_2^{-1}(s) & s < -c - \epsilon \text{ and } s > c, \\ M_{2,\epsilon}(s)P_{2,\epsilon}^{-1}(s) & -c - \epsilon < s < -c, \\ M_{2,\epsilon}(s)\sigma_1 P_{2,\epsilon}^{-1}(s) & -c < s < -c + \epsilon, \\ M_{2,\epsilon}(s) & \text{Im} s < 0, \ |s + c| = \epsilon, \\ P_{2,\epsilon}(s) & \text{Im} s > 0, \ |s + c| = \epsilon. \end{cases} \tag{B.33}$$

The jump on the real axis, inside the circle, is nearly of the form:

$$W^+(s) = W^-(s) \begin{cases} \sigma_1 & s > -c, \\ I & s < -c. \end{cases} \tag{B.34}$$

To find such a solution $W$ we first perform an eigen decomposition

$$\sigma_1 = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}. \tag{B.35}$$

Then we solve a matrix problem (keeping an identity condition at infinity)

$$V^+(z) = V^-(z) \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, \quad V(z) = \begin{bmatrix} \sqrt{\frac{-z + c}{z + c}} & 0 \\ 0 & 1 \end{bmatrix}. \tag{B.36}$$

We find the solution

$$W(z) = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{-z + c}{z + c}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{-z + c}{z + c}} & 0 \\ 0 & 1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} -1 - \sqrt{\frac{-z + c}{z + c}} & 0 \\ 0 & 1 + \sqrt{\frac{-z + c}{z + c}} \end{bmatrix} \cdot \tag{B.37}$$

We note that $W(-z)$ is also a solution. Then, perform the transformation, for $z \not\in \mathbb{R} \cup \{|z + c| = \epsilon\}$,

$$N_{2,2}(z) = N_{2,1}(z) \begin{cases} I & |z + c| > \epsilon, \\ W^{-1}(z) & |z + c| < \epsilon. \end{cases} \tag{B.38}$$

For $-c - \epsilon < z < -c + \epsilon$, $z \neq 0$, the resulting jump for the function $N_{2,2}(z)$ is given by

$$G_{-c}(s) = W_-(s)M_{2,\epsilon}(s)W_-^{-1}(s)W_+(s)P_{2,\epsilon}^{-1}(s)W_+^{-1}(s). \tag{B.39}$$
We want this to be continuous and equal to the identity jump at \( s = 0 \). Note that for \( \kappa(z) = \sqrt{1 + c/z} \)

\[
H(s) = W_{\pm}(s) \begin{bmatrix} 1 & f(s) \\ 0 & 1 \end{bmatrix} W^{-1}_{\pm}(s) = \frac{1}{4} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 2 - f(s) & f(s)\kappa_{\pm}(s) \\ -f(s)\kappa_{\pm}^{-1}(s) & 2 + f(s) \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}.
\]

(B.40)

So, if \( f(s) = O(|s + c|) \) as \( s \to -c \), \( H(s) = I + O(|s + c|^{1/2}) \) as \( s \to -c \). While the jump condition for \( N_{22}(z) \) behaves nicely near \( z = -c \), we do not know that the solution itself does.

Let \( \Phi : \mathbb{R} \to \mathbb{R} \) be infinitely differentiable, non-negative, \( \Phi(s) = 1 \) for \( |s| < \epsilon/4 \) and \( \Phi(s) = 0 \) for \( |s| > \epsilon/2 \). Then consider the \( L^2 \) RH problem

\textbf{Riemann--Hilbert Problem 5.}

\[
L_+^+(s) = L^-_-(s)[I + \Phi(s-c)(G_{N_2}(s) - I)], \quad -c - \epsilon < s < c + \epsilon, \quad L(\cdot) - I \in H_{\pm}^1(\mathbb{R}).
\]

(B.41)

For \( \epsilon \) sufficiently small, it follows that this problem is uniquely solvable because the associated singular integral operator is a near-identity operator. And because the jump matrix is \( 1/2 \)-Hölder continuous by assumptions (1, 4), so is the solution, giving \( 1/2 \)-Hölder continuous boundary values [28]. Furthermore, \( \det L(z) \neq 0 \). Then set

\[
N_{22}(z) = N_{21}(z) \begin{cases} 1 & |z + c| > \epsilon, \\ W^{-1}_1(z) L^{-1}_1(z) & |z - c| \leq \epsilon. \end{cases}
\]

(B.42)

It follows that \( N_{22}(z) \) has an identity jump in a neighborhood of \( z = -c \).

\textbf{Lemma B.8.} Let \( \Gamma \) be a differentiable curve parameterized by \( \gamma : [-1,1] \to \Gamma, \gamma(t) = t + i\ell(t), \ell(0) = 0 \) and define \( \Gamma_\epsilon = \gamma((-1 + \epsilon, 1 - \epsilon)) \). Assume \( g \) is analytic in an the open set \( \bigcup_{0 < |r| < R} (\Gamma_\epsilon + ir) \) and satisfies

\[
\sup_{-R < 2 \epsilon < R, r \neq 0} \int_{\Gamma_\epsilon} |g(s + ir)|^2 \, ds < \infty,
\]

(B.43)

for some \( R > 0 \) and \( 0 < \epsilon < 1/2 \). Then, assume the branch of \( z \mapsto z^{-1/2}g(z) \) is chosen so that \( h(z) = z^{-1/2}g(z) \) has an isolated singularity at \( z = 0 \). Then \( h \) is analytic at \( z = 0 \).

\textbf{Proof.} First consider \( f(z) = z^{1/2}g(z) \). This has an isolated singularity at \( z = 0 \) and it satisfies

\[
\sup_{0 < |r| < R} \int_{\Gamma_\epsilon} |f(s + ir)|^2 \, ds < \infty.
\]

(B.44)

It then follows that \( f \in \mathcal{E}^2(C_\pm) \) where \( C_\pm = \bigcup_{0 < r < R/2} (\Gamma_\epsilon \pm ir) \). For sufficiently small \( \epsilon > 0 \)

\[
\int_{\partial B(0, \epsilon)} f(z) \, dz = \int_{\partial B(0, \epsilon) \cap C_+} f(z) \, dz + \int_{\partial B(0, \epsilon) \cap C_-} f(z) \, dz \\
+ \int_{\Gamma_\epsilon \cap B(0, \epsilon)} f(z) \, dz - \int_{\Gamma_\epsilon \cap B(0, \epsilon)} f(z) \, dz = 0.
\]

(B.45)
The same is true for $v_k(z)$ for all integers $k > 0$. Thus $f$ is analytic at $z = 0$. We now claim that $f(0) = 0$. Assume

$$f(z) = c + o(1), \quad z \to 0, \quad c \neq 0. \quad (B.46)$$

There exists $\delta > 0$, so that for $|z| < \delta, |f(z)| \geq |c|/2$. Then $|h(z)| \geq |c||z|^{-1/2}/2$ for $|z| < \delta$. Then consider for $0 < r < R$

$$\int_{t_1}^{t_2} |h(z + ir)|^2 \, dz \geq \frac{|c|^2}{4} \int_{t_1}^{t_2} |z + ir|^{-1} \, dz. \quad (B.47)$$

Then using the parameterization

$$\int_{t_1}^{t_2} \frac{dt}{\sqrt{r^2 + \ell^2(t) + r}} \geq \int_{t_1}^{t_2} \frac{dt}{\sqrt{1 + C^2|t| + r}} \geq \frac{1}{\sqrt{1 + C^2}} \log \left( 1 + \frac{\sqrt{1 + C^2}t_1}{r} \right). \quad (B.48)$$

This right-hand side tends to $\infty$ as $r \to 0$, contradicting (B.43). Thus $f(0) = 0$. Then it follows that $\int_{B(0,\epsilon)} \frac{\partial}{\partial z}h(z) \, dz = 0$ for all positive integers $k$ and $h$ must be analytic at $z = 0$. □

Applying this lemma to $N_{2,3}(z)$ near $z = -c$ we find that it is indeed analytic in a neighborhood of $z = -c$. Specifically, each component of $N_{2,3}$, inside the circle $|z + c| < \epsilon$ will be of the form

$$h_1(z)\phi_1(z) + \frac{h_2(z)\phi_2(z)}{\sqrt{z + c}}, \quad (B.50)$$

where $\phi_j$ are bounded analytic functions for $\text{Im} z \neq 0$ and $h_j$ satisfy the estimate

$$\sup_{0 < \epsilon < R} \int_{-\delta}^\delta |h_j(s \pm ir)|^2 \, ds < \infty \quad \text{for some} \ \delta > 0, \ R > 0.$$  

So we apply the lemma to $g(z) = \sqrt{z + c}h_1(z)\phi_1(z) + h_2(z)\phi_2(z). \quad (B.51)$

We are led to the following $L^2$ RH problem for $N_{2,3}$:

**Riemann–Hilbert Problem 6.** Giving the circle $\{|s + c| = \epsilon\}$ a clockwise orientation

$$N_{2,3}^+(s) = N_{2,3}^-(s)J_{2,3}(s) = N_{2,3}(s) \begin{bmatrix} M_2(s)P_3^{-1}(s) & s < -c - \epsilon \text{ and } s > c, \\ L_-(s)G_{-\epsilon}(s)L_{-\epsilon}^{-1}(s) & -c - \epsilon < s < -c + \epsilon, \\ M_2(s)\phi_1P_2^{-1}(s) & -c + \epsilon < s < c, \\ M_{2,\epsilon}(s)W^{-1}(s)L_\epsilon^{-1}(s) & \text{Im} s < 0, |s + c| = \epsilon, \\ P_{2,\epsilon}(s)W^{-1}(s)L_\epsilon^{-1}(s) & \text{Im} s > 0, |s + c| = \epsilon \end{bmatrix} \quad (B.52)$$

with $N_{2,3}(\cdot) - I \in H_2^\infty(\mathbb{R} \cup \{|s + c| = \epsilon\})$.

To complete the proof of theorem 3.15, we perform the following steps:

(1) We perform a similar deformation of RH problem 4 near $z = c$ using symmetry considerations.

2263
Then we show the resulting singular integral operator is Fredholm, and show that it is index zero using a homotopy argument.

Then to show the kernel is trivial, we show that every distinct element of the kernel results in a distinct vanishing solution of RH problem 3.

Step (1) is given as a RH problem. We separate (2)–(4) into three lemmas. The fact that

\[ \sigma_1 M_2(-s) \sigma_1 = P_2(s) \]  
(B.53)

implies

\[ \sigma_1 M_2(-z) P_2^{-1}(-z) \sigma_1 = \sigma_1 M_2(-z) \sigma_1 P_2^{-1}(-z) \sigma_1 = P_2(z) M_2^{-1}(z) = \left( M_2(z) P_2^{-1}(z) \right)^{-1}. \]  
(B.54)

This similarly holds for

\[ \sigma_1 M_2(-s) \sigma_1 P_2^{-1}(-s) \sigma_1 = \left( M_2(s) \sigma_1 P_2^{-1}(s) \right)^{-1}. \]  
(B.55)

This is a necessary condition for \( N_2(-z) \left[ \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right] = N_2(z) \) when \( N_2 \) is a solution of RH problem 4.

Orient the circle \( \{ |s - c| = \epsilon \} \) with a clockwise orientation and define an \( L^2 \) RH problem that is regular at \( \pm c \).

**Riemann–Hilbert Problem 7.** The function \( N_{2,4}(\cdot) - \left[ \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right] \in H_+^2(\Gamma) \)

\[ N_{2,4}^+(s) = N_{2,4}^-(s) J_{2,4}(s), \quad s \in \Gamma, \]  
(B.56)

where

\[ \Gamma = \mathbb{R} \cup \{ |s + c| = \epsilon \} \cup \{ |s - c| = \epsilon \}, \]  
(B.57)

and

\[ J_{2,4}(s) = \begin{cases} J_{2,3}(s) & \text{Re} \, s \leq 0, \\ \sigma_1 J_{2,3}^{-1}(-s) \sigma_1 & \text{Re} \, s > 0. \end{cases} \]  
(B.58)

Furthermore, \( N_{2,4} \) satisfies the symmetry condition

\[ N_{2,4}(-z) \left[ \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right] = N_{2,4}(z), \quad z \in \mathbb{C} \setminus \Gamma. \]  
(B.59)

**Lemma B.9.** The operator

\[ u \mapsto \begin{cases} u(s) - C^{-1} u(s)(J_{2,4}(s) - I) & s \in \Gamma, \, \text{Re} \, s \leq 0, \\ u(s) J_{2,4}^{-1}(s) - C^{-1} u(s)(I - J_{2,4}^{-1}(s)) & s \in \Gamma, \, \text{Re} \, s > 0, \end{cases} \]  
(B.60)

is Fredholm on \( L^2_+(\Gamma) \) where \( \Gamma \) is given in (B.57). Furthermore, the Fredholm index is zero.

**Proof.** This RH problem satisfies the zeroth-order product condition [39, definition 2.55] with continuous jump matrices. Furthermore, \( R_\epsilon \) in addition to being continuous, decays at infinity by assumption (11), thus the operator
\[ \mathbf{u} \mapsto \mathbf{u} - C_{\Gamma}^{-} \mathbf{u} \cdot (J_{2,4} - \mathbf{I}) \quad (B.61) \]

is Fredholm on \( L^2(\Gamma) \). This implies that the operator (B.60) is also Fredholm on \( L^2(\Gamma) \). Because of the enforced symmetry of \( J_{2,4} \), this operator also maps \( L^2(\Gamma) \) to itself (see lemma B.4), and is therefore Fredholm on \( L^2(\Gamma) \). Now, to show that the index is zero, we replace \( R \) with \( aR \), for \( 0 \leq a \leq 1 \). It follows that \( J_{2,4} \rightarrow J_{\infty} \), uniformly for \( s \in \Gamma \), as \( \alpha \rightarrow 0 \) where \( J_{\infty}(s) \) for \( \text{Re} \, s \leq 0 \) is given by

\[ J_{\infty}(s) = \begin{cases} \sigma_1 & -c + \epsilon < s \leq 0, \\ W^{-1}(s) & |s + c| = \epsilon \end{cases} \quad (B.62) \]

and

\[ J_{\infty}(s) = \sigma_1 J_{\infty}^{-1}(-s) \sigma_1, \quad \text{Re} \, s > 0. \quad (B.63) \]

We construct the inverse operator to

\[ \mathbf{u} \mapsto \mathbf{u} - C_{\Gamma}^{-} \mathbf{u} \cdot (J_{\infty} - \mathbf{I}) = C_{\Gamma}^{+} \mathbf{u} - C_{\Gamma}^{-} \mathbf{u} \cdot J_{\infty}, \]

\[ \Gamma' = [-c + \epsilon, c - \epsilon] \cup \{ |s + c| = \epsilon \} \cup \{ |s - c| = \epsilon \}, \quad (B.64) \]

explicitly, and use this to show that the index of (B.60) is zero.

Consider the operator

\[ \mathbf{u} \mapsto C_{\Gamma}^{+}((\mathbf{u} \cdot W_{-}^{-1})W_{+} - C_{\Gamma}^{-}(\mathbf{u} \cdot W_{+}^{-1})W_{-}), \quad (B.65) \]

and its composition with (B.64) by considering

\[ C_{\Gamma}^{+}((C_{\Gamma}^{+} \mathbf{u} - C_{\Gamma}^{-} \mathbf{u} \cdot J_{\infty}) \cdot W_{-}^{-1})W_{+} = C_{\Gamma}^{+} \mathbf{u} - C_{\Gamma}^{-} (C_{\Gamma}^{+} \mathbf{u} \cdot W_{+}^{-1})W_{+} = C_{\Gamma}^{+} \mathbf{u}, \]

\[ C_{\Gamma}^{-}((C_{\Gamma}^{+} \mathbf{u} - C_{\Gamma}^{-} \mathbf{u} \cdot J_{\infty}) \cdot W_{+}^{-1})W_{-} = C_{\Gamma}^{-} \mathbf{u}. \quad (B.66) \]

This shows that (B.65) is the left inverse of (B.64). Similar considerations show it is also the right inverse. Now, this implies an inverse for (B.60) on \( L^2(\Gamma') \) when \( s = 0 \):

\[ \mathbf{u} \mapsto C_{\Gamma}^{+}((\mathbf{u} \cdot \hat{W})W_{+} - C_{\Gamma}^{-}(\mathbf{u} \cdot \hat{W})W_{-}), \quad \hat{W}(z) = \begin{cases} W_{+}^{-1}(z) & \text{Re} \, z \leq 0, \\ W_{+}^{-1}(z) & \text{Re} \, z > 0 \end{cases} \quad (B.67) \]

It is then enough to show that this operator maps \( L^2(\Gamma') \) to itself\(^9\). This follows from theorem B.5.

Lemma B.10. The kernel of the operator (B.60) is trivial, and therefore RH problem 7 has a unique \( L^2 \) solution for any \( \epsilon > 0 \) sufficiently small.

Proof. The following transformation essentially maps the function \( N_2 \) to \( N_1 \), with the exception of the exponentials,

\(^9\) Note that (B.60) is the identity operator on \( \Gamma \setminus \Gamma' \) for \( s = 0 \).
\[ T \mathbf{N}_2(z) := \begin{cases} \mathbf{N}_2(z) \mathbf{e}^{-i(\lambda(z)x + 4i\phi(z)\tau)e_3} \begin{bmatrix} A(z) & 0 \\ 0 & 1 \end{bmatrix} \sigma_1 \begin{bmatrix} \frac{1}{a(z)} & 0 \\ 0 & 1 \end{bmatrix}, & \text{Im } z > 0, \\ \mathbf{N}_2(z) \mathbf{e}^{-i(\lambda(z)x + 4i\phi(z)\tau)e_3} \begin{bmatrix} 1 & 0 \\ 0 & A(-z) \end{bmatrix} \sigma_1 \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{a(-z)} \end{bmatrix}, & \text{Im } z < 0. \end{cases} \] (B.68)

This should be equal to \( \mathbf{N}_1(z) \mathbf{e}^{(i\tau z + 4i\tau \phi(z))e_3} \). So, let \( \mathbf{u} \) be an element of the kernel of (B.60). Define for \( z \not\in \Gamma \), \( (\Gamma \) is given in (B.57))

\[ Y(z) = \begin{cases} \mathcal{C}_T \mathbf{u}(z), & \text{if } |z + c| < \epsilon, \ |z - c| < \epsilon, \\ \mathcal{C}_T \mathbf{u}(z), & \text{otherwise.} \end{cases} \] (B.69)

Of particular interest are the jumps on \( |s \pm c| = \epsilon \). On this circle for \( \text{Im } s > 0 \)

\[ Y^+(s) = Y^-(s) \sigma_1 \begin{bmatrix} \frac{1}{\text{Im } s} & 0 \\ 0 & a(s) \end{bmatrix} \mathbf{P}_{2,\alpha}(s) \mathbf{W}^{-1}(z) \mathbf{L}^{-1}(z) := Y^-(s) \mathbf{R}(s). \] (B.70)

We must compute the inverse of this jump matrix

\[ \mathbf{R}_{-c,+}(z) = \mathbf{L}(z) \mathbf{W}(z) \mathbf{P}_{2,\alpha}(z) \mathbf{e}^{-(2i\lambda(z)x + 8i\phi(z)\tau)e_3} \begin{bmatrix} A(z) & 0 \\ 0 & \frac{1}{a(z)} \end{bmatrix} \sigma_1 \] (B.71)

and we focus on the product, with the notation \( f(z) = -\mathbf{L}_{-c}(z) \mathbf{e}^{2i\lambda(z)x + 8i\phi(z)\tau} \)

\[ \mathbf{W}(z) \mathbf{P}_{2,\alpha}^{-1}(z) = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{z+c}{z-c}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ -f(z) & 1 \end{bmatrix} 
= \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{z+c}{z-c}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 + f(z) & -1 \\ 1 - f(z) & 1 \end{bmatrix} \] (B.72)

\[ = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 1 + f(z) \sqrt{\frac{z+c}{z-c}} & -\sqrt{\frac{z+c}{z-c}} \\ 1 - f(z) & 1 \end{bmatrix}. \]

We know that \( A(z) \) blows up as a square root at \( z = -c \) by assumptions (2, 7), so for (B.71) to be bounded for \( |z + c| \leq \epsilon, \text{Im } z > 0, \) \( f(-c) = 1 \) is required, and because \( \mathbf{R}_c \) is \( 1/2 \)-Hölder continuous, we have \( \mathbf{L}_{-c}(z) = -1 + O(|z + c|^{1/2}). \) This shows that (B.71) is a bounded analytic function. Similarly,

\[ \mathbf{W}(z) \mathbf{M}_{2,\alpha}^{-1}(z) = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{z+c}{z-c}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & -f(-z) \\ 1 & f(-z) \end{bmatrix} 
= \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{z+c}{z-c}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} -f(-z) & 1 \\ 1 & 1 - f(-z) \end{bmatrix} \] (B.73)

\[ = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{\frac{z+c}{z-c}} & -\sqrt{\frac{z+c}{z-c}}(f(-z) + 1) \\ 1 & 1 - f(-z) \end{bmatrix}, \]
shows that
\[
R_{c,-}(z) = L(z)W(z)M_2^{-1}(z) e^{-\left(2i\lambda(z)x+8i\varphi(z)\right)\sigma_3} \begin{bmatrix}
\frac{1}{a(-z)} & 0 \\
0 & A(-z)
\end{bmatrix} \sigma_1,
\]
(B.74)
is a bounded analytic function for \(\{|z+c| < \epsilon\}, \text{ Im } z < 0\) because \(L_{-c}(-z) = -1 + O(|z+c|^{1/2})\). If we define for \(\text{Re } z \leq 0\)
\[
Z(z) = \begin{cases}
C_1 u(z) R_{c,+}(z) & |z+c| < \epsilon, \text{ Im } z > 0, \\
C_1 u(z) R_{c,-}(z) & |z+c| < \epsilon, \text{ Im } z < 0, \\
T C_1 u(z), & \text{otherwise}
\end{cases}
\]
(B.75)
and \(Z(z) = Z(-z)\sigma_1\) for \(\text{Re } z > 0\), we obtain a function with \(L^2(\mathbb{R})\) boundary values and no jumps on \(|s \pm c| = \epsilon\).
Then it follows that
\[
Z(z) e^{(2i\lambda x+8i\varphi)\sigma_3},
\]
(B.76)
is a solution of RH problem 3, by (122) and (123), with \(Z \in H^2_\pm(\mathbb{R})\), and therefore \(Z = 0\). This implies \(u = 0\).
□

The last step is to establish the following injection.

**Lemma B.11.** Every \(L^2\) solution of RH problem 7 corresponds to one and only one solution of RH problem 4.

**Proof.** The careful derivation of RH problem 7 implies that each solution of RH problem 4 can be deformed to a solution of RH problem 7 for any \(\epsilon\) sufficiently small. Because the functions \(L(z)W(z)P_{2,0}(z)\) and \(L(z)W(z)M_2(z)\) are bounded analytic functions in the domains \(\{|z+c| < \epsilon, \text{ Im } z > 0\}\) and \(\{|z+c| < \epsilon, \text{ Im } z < 0\}\), respectively. This allows the inversion of the deformations, so that each \(L^2\) solution of RH problem 7 gives an \(L^2\) solution of RH problem 4.
□

Given two distinct solutions \(N_1^{(1)}(z)\) and \(N_2^{(2)}(z)\) of RH problem 4, they must differ at some point \(z^*\), \(N_2^{(1)}(z^*) \neq N_2^{(2)}(z^*)\), \(z^* \notin \mathbb{R}\). Then \(\min\{|z^*-c|, |z^*+c|\} > \delta\) for some \(\delta > 0\).
We perform the deformation to RH problem 7 for \(0 < \epsilon < \delta\) for each solution, and lemma B.10 gives a contradiction, and establishes uniqueness. The existence is also guaranteed by lemmas B.10 and B.11.
