Abstract

We consider the classical equations of the Einstein-Yang-Mills model in five space-time dimensions and in the presence of a cosmological constant. We assume that the fields do not depend on the extra dimension and that they are spherically symmetric with respect to the three standard space dimensions. The equations are then transformed into a set of ordinary differential equations that we solve numerically. We construct new types of regular (resp. black holes) solutions which, close to the origin (resp. the event horizon) resemble the 4-dimensional gravitating monopole (resp. non abelian black hole) but exhibit an unexpected asymptotic behaviour.

I. INTRODUCTION

In the last years, there has been an increasing attention to space-times involving more than four dimensions and particularly to brane-world models \[1\] to describe space, time and matter. These assume the standard model fields to be confined on a 3-brane embedded in a higher dimensional manifold. A large number of higher dimensional black holes has been studied in recent years. The first solutions that have been constructed are the hyperspherical generalisations of well-known black holes solutions such as the Schwarzschild and Reissner-Nordström solutions in more than four dimensions \[2\] as well as the higher dimensional Kerr solutions \[3\]. In \(d\) dimensions, these solutions have horizon topology \(S^{d-2}\).

However, in contrast to 4 dimensions black holes with different horizon topologies should be possible in higher dimensions. An example is a 4-dimensional Schwarzschild black hole extended trivially into one extra dimension, a so-called Schwarzschild black string. These solutions have been discussed extensively especially with view to their stability \[4\]. A second example, which is important due to its implications for uniqueness conjectures for black holes in higher dimensions, is the black ring solution in 5 dimensions with horizon topology \(S^2 \times S^1\) \[5\].

The by far largest number of higher dimensional black hole solutions constructed so far are solutions of the vacuum Einstein equations, respectively Einstein-Maxwell equations.

On the other hand, it is believed that topological defects have occurred and played a role during some phase transitions in the evolution of the Universe, see e.g. \[6\]. In particular, magnetic monopoles \[7\] must have been produced during the GUT symmetry breaking phase transition. The actual non-observation of magnetic monopoles leads to constraints which have to be implemented into the models of inflation. On the other hand observational evidence obtained in the last years \[8\] favours the possibility that space-time has an accelerated expansion which could be related to a positive cosmological constant.

It is therefore natural to examine the properties of the various topological defects in presence of a cosmological constant, or said in other words, in asymptotically DeSitter space-time. Recently \[9\] the magnetic monopole and the sphalerons occurring in an SU(2) gauge theory spontaneously broken by a scalar potential were constructed in an asymptotically DeSitter space-time and it was found that the asymptotic decay of the matter field is not compatible with a finite mass.
The first example of higher dimensional black hole solutions containing non-abelian gauge fields have been discussed in [10]. These are non-abelian black hole solutions of a generalised 5-dimensional Einstein-Yang-Mills system with horizon topology $S^3$. Using ideas of [11, 12], SU(2)-black strings with $S_2 \times S_1$ topology were constructed in [13]. Several regular and black hole solutions of an Einstein-Yang-Mills model have been constructed recently with different symmetries [14, 15, 16]. These solutions are non-abelian black hole solutions in 3+1-dimensions extended to one extra dimension.

In [17, 18] the Einstein-Yang-Mills model in five dimensions with gauge group SU(2) was considered with a positive cosmological constant. The metric and gauge fields were assumed to be independent of the extra dimension and chosen to be spherically symmetric in the standard three space-like dimensions. By adopting a Schwarzschild-dilaton type parametrisation for the metric, it was found that the equations can be integrated only up to a maximal value of the radial coordinate, say $r = r_c$. A coordinate singularity occurs at $r = r_c$. In this paper, we adopt the parametrisation of the metric used in [19] and we show that the solution of [18] can be extended up to spatial infinity in these coordinates.

We give the model and the two parametrisation of the metric in Sect. II. The relevant reduced action for the gravitating and matter parts are presented in Sect. III together with the boundary conditions. The numerical results corresponding to solutions regular at the origin and solutions possessing an event horizon are discussed in IV. The summary is given in Section V.

II. THE MODEL AND THE ANSATZ

The Einstein-Yang-Mills Lagrangian in $d = (4 + 1)$ dimensions is given by:

$$S = \int \left( \frac{1}{16\pi G_5} (R - 2\Lambda_5) - \frac{1}{4e^2} F_{MN}^a F^{aMN} \right) \sqrt{g^{(5)}} d^5 x$$

(1)

with the SU(2) Yang-Mills field strengths $F_{MN}^a = \partial_M A_N^a - \partial_N A_M^a + \epsilon^{abc} A_M^b A_N^c$, the gauge index $a = 1, 2, 3$ and the space-time index $M = 0, ..., 5$. $G_5$, $\Lambda_5$ and $e$ denote respectively the 5-dimensional Newton’s and cosmological constants and the coupling constant of the gauge field theory. $G_5$ is related to the Planck mass $M_{pl}$ by $G_5 = M_{pl}^{-3}$ and $e^2$ has the dimension of [length].

In this paper, we assume that the metric and the matter fields are independent on the
extra coordinate $y$ and we will use a spherically symmetric ansatz for the fields.

Our aim is to construct non-abelian regular and black strings solutions which are spherically symmetric in the four-dimensional space-time and are extended into one extra dimension. The topology of these non-abelian black strings will thus be $S^2 \times \mathbb{R}$ or $S^2 \times S^1$ if the extra coordinate $y$ is chosen to be periodic.

We will use two different coordinates systems for the metric. On the one hand, the metric can be parametrized according to [11] as follows

$$ g^{(5)}_{MN} dx^M dx^N = e^{-\xi} \left[ -A^2 N dt^2 + N^{-1} dr^2 + r^2 d\theta^2 + r^2 \sin^2 \theta d\varphi^2 \right] + e^{2\xi} dy^2 : \text{type}(1) $$

where $N, A, \xi$ are function of the coordinate $r$ only. For the gauge fields, we use the spherically symmetric ansatz [7]:

$$ A^a_r = A^a_t = 0, \quad A^a_\theta = (1 - K(r)) e^a_\varphi, \quad A^a_\varphi = -(1 - K(r)) \sin \theta e^a_\theta, \quad \Phi^a = vH(r) e^a_r $$

where $v$ is a mass scale.

The classical equations corresponding to the model above were studied in [17] and more recently in [18] with the appropriate boundary conditions corresponding to regular solution at the origin $r = 0$ and black string solutions presenting a regular event horizon on a cylinder, i.e. with $N(r_h) = 0$. The equations were solved numerically and it was found that the solutions having the regular behaviour at $r = 0$ or $r = r_h$ exist only up to a maximal value $r = r_c$ (with the value $r_c$ depending on both $\alpha$ and $\Lambda$). For $r \to r_c$ the fields behave according to

$$ N(r) \sim N_c(r_c - r), \quad \xi(r) \sim \xi_i + \xi_c \sqrt{(r_c - r)}, \quad A(r) = A_c(r_c - r)^{-a} $$

where $N_c, \xi_i, \xi_c, A_c, a$ are constants (with $a > 0$) depending on $\alpha$ and $\Lambda$. The behaviour of the function $\xi$ clearly indicates an absence of analyticity at $r = r_c$.

In view of these difficulties, we have tried to study the equation by using a different parametrisation of the metric. For instance, we use the length element used e.g. in [19]. It reads

$$ ds^2 = -b(x) dt^2 + \frac{dx^2}{f(x)} + g(x) \left( d\theta^2 + \sin^2(\theta) d\varphi^2 \right) + a(x) dy^2 : \text{type}(2) $$

where the radial variable is named $x$ (to avoid confusion with $r$ used in (2)). The arbitrary redefinition of the coordinate $x$ is left unfixed at this stage but on it will be fixed later according to $g(x) = x^2$. The ansatz for the matter fields is identical to (3) apart from
the fact that the functions $K, H$ now depend on $x$. Using $g(x) = x^2$ as gauge fixing, the correspondence between the two sets of functions in (2) and (5) reads:
\[ x = re^{-\xi(r)/2}, \quad f(x) = N(1 - \frac{r d\xi}{2 dr})^2, \quad a(x) = e^{2\xi(r)}, \quad b(x) = A(r)^2N(r)e^{-\xi(r)} \]

III. EQUATIONS OF MOTION

Using an appropriate rescaling of the radial variable $evx \rightarrow x$, the classical equations associated to the action (1) lead to a set of ordinary differential equations depending on the fundamental coupling $\alpha \equiv 4\pi \sqrt{G} v$ and on the reduced cosmological constant $\Lambda \equiv 2\alpha^2\Lambda_5$. In the case of the parametrisation (2), the equations are written in details in [18] together with the appropriate boundary conditions. In the case of the parametrisation (3), the equations are lengthy. They can be obtained easily for the reduced action
\[ S_{\text{red}} = \sqrt{-\tilde{g}} \frac{1}{\sin \theta} R + S_{\text{mat}}, \quad \sqrt{-\tilde{g}} = g \sin \theta \sqrt{ab/f} \]

with the gravitating part proportional to the Ricci scalar
\[ \sqrt{-\tilde{g}} \frac{1}{\sin \theta} R = -\left( \sqrt{abf} \left( g\left( \frac{b'}{b} + \frac{a'}{a} \right) + 2g' \right) \right)' + g \sqrt{abf} \left( \frac{g'}{g^2} (\frac{a'}{a} + \frac{b'}{b}) + \frac{2}{g} + \frac{f}{2ab} \right) \]

and
\[ S_{\text{mat}} = \sqrt{-\tilde{g}} \left( \frac{K'^2}{fg} + \frac{1}{2g^2} (1 - K^2)^2 + \frac{1}{2} \frac{H'^2}{f} + \frac{1}{g} K^2 H^2 \right) \]

where the prime denote derivative with respect to the rescaled radial variable $x$.

A. Boundary conditions

In the type 2 system of coordinates, it should be noticed that the function $a$ and $b$ can be rescaled arbitrarily. The regularity conditions for a regular solution at the origin read
\[ f(0) = 1, \quad a(0) = 1, \quad b(0) = 1, \quad b'(0) = 0 \]

while black strings possessing an horizon at $x = x_h$ should have
\[ f(x_h) = 0, \quad a(x_h) = 1, \quad b(x_h) = 0, \quad b'(x_h) = 1 \]
in both case a natural choice of the normalisation of \( a, b \) has been supplemented. For the matter fields, the boundary conditions for a regular solution at the origin and the usual asymptotic conditions read

\[
K(0) = 1 \ , \ H(0) = 0 \ , \ K(\infty) = 0 \ , \ H(\infty) = 1 \ , \quad (12)
\]

In the case of black holes, the regularity at the horizon imposes some peculiar relations between the values \( H(x_h), K(x_h) \) and of their derivatives. These expressions are cumbersome and will not be presented here.

B. Kasner-type solutions

The study of the classical equations in the vacuum case, i.e. for \( K(x) = 1, H(x) = 0 \) is interesting by itself. A complete analysis of black strings in the case of a negative cosmological constant is reported in \[19\]. In that paper, solutions were constructed numerically which grow asymptotically according to

\[
a(x) = \frac{x^2}{\ell^2} \ , \ b(x) = \frac{x^2}{\ell^2} \ , \ f(x) = \frac{x^2}{\ell^2} \quad \text{with} \quad \Lambda \equiv -\frac{6}{\ell^2} \quad (13)
\]

(the next terms of these expansions can be found in \[19\]). Obviously, solutions with the corresponding asymptotic expansion can be expected in the present context of a positive cosmological constant.

For both cases (i.e. \( \Lambda < 0 \) and \( \Lambda > 0 \)) however, we obtained another type of asymptotic solutions. This reads

\[
a = x^{2A} \ , \ b = x^{2B} \ , \ f = f_0 x^{2F} \quad \text{with} \quad A = B = -2 - \sqrt{3} \ , \ F = 3 + 2\sqrt{3} \quad (14)
\]

and where \( f_0 \) is a constant. The power-dependence of the metric functions on the radial coordinate is reminiscent of the well known Kasner solution in four-dimensional space-time. It can be checked easily that the Ricci scalar corresponding to these solutions vanishes asymptotically.
IV. NUMERICAL RESULTS

A. Regular solutions

We solved the equations corresponding to the lagrangian (1) by numerical methods for several values of $\alpha$ and $\Lambda > 0$. In the system of coordinate (5), our results strongly suggest that the solutions approaching the regular boundary condition at the origin can be extrapolated for $x \to \infty$ and that, in this asymptotic limit, they approach a Kasner-type solution (14). This is illustrated on Fig. 1 for $\alpha = 1, \Lambda = 0.0005$. Close to the origin, these solutions are similar to the gravitating dilatonic monopole but contrary to our expectation they do not extrapolate to a DeSitter space-time for $\Lambda > 0$. It seems that the presence of the cosmological constant and the corresponding Liouville potential leads to an asymptotic space-time obeying the power law (14) asymptotically.

In order to confirm this result, we also considered the equations in the case $\alpha = 0$ where the matter fields trivialize by means of $K = 1, H = 0$. The equations therefore correspond to 5-dimensional gravity in the presence of a positive cosmological constant. The profiles of the functions $a, b, f$ are represented in the subplot of Fig. 3. Comparing Figs.1 and 3, we can appreciate the significant deformation of the functions $a, b, f$ due to the matter fields in the region $x \sim 0$.

The double logarithmic scale used on Fig. 3 demonstrates the power decay of the metric functions. Our numerical results strongly indicate that $a(x) = b(x)$ in this case. This relation does not hold true for black strings (see next section) but it suggests that the solution could be expressed in an explicit form (although we failed to find it so far). To finish this section, let us mention that, in the case of a negative cosmological constant, a solution regular at the origin also exists; it was constructed in [19]. In contrast to the present case, the solution of [19] approaches asymptotically the solution (13).

B. Black hole solutions

The numerical construction of black hole solutions of the lagrangian (1) is more difficult with the type-2 parametrisation of the metric than with the type-1 parametrisation because two functions (for instance $f$ and $b$) vanish at the event horizon $x_h$, leading to several singular terms in the equations (with the type-1 parametrisation, we have $N(r_h) = 0$ only).
Nevertheless, the results of [18] suggest that such solutions exist at least locally. Moreover, the solutions constructed with the type-1 coordinate provide suitable starting profiles for the different functions. It is worth noticing that, once converted into the type-2 coordinate system by means of (6) the functions $a, b, f$ and their derivatives turn out to be smooth in the neighbourhood of the maximal value $x_c = r_c e^{-\xi(r_c)/2}$. Solving the equations for the type-2 coordinates confirms indeed the non abelian black string of [18] and further shows that these solutions can be extended for $x \in [x_h, \infty]$ with $\Lambda > 0$.

The profile for such a solution is presented on Fig. 2 for $\alpha = 1, x_h = 0.3$ and $\Lambda = 0.0005$. Similarly to the case of regular solutions our numerical results strongly suggest that these black hole solution extrapolate between the condition of a regular black string with horizon at $x = x_h$ and the Kasner-type behaviour (14) for $x \to \infty$.

We also solved the equations in the pure gravity case (i.e. $\alpha = 0$ and $W = 1, H = 0$) and obtained the black string solutions with positive cosmological constant. These are represented on Fig. 3 (main figure). These solutions are the counterparts for $\Lambda > 0$ of the black string solutions presented in [19] for $\Lambda < 0$. Let us point out that for $\Lambda < 0$ the black string solutions extrapolate between a regular horizon and ADS space-time. In the neighbourhood of the event horizon $x_h$ the two solutions look quite similar but they deviate considerably from each other for $x > 1$.

Let us finally mention that, integrating the equations from $x = \infty$ with (13) as initial condition and with $\Lambda > 0$ leads to configurations which become singular for $x \to 0$. A systematic study of black string with $\Lambda > 0$ and $d > 4$ will be presented elsewhere [20].

V. SUMMARY

The construction of solitons and black string solutions for the Einstein-Yang-Mills equations in a five-dimensional space-time and in the presence of a cosmological constant turns out to be numerically difficult. The problem was addressed in [18] but it appeared that the system of coordinates used was not satisfactory, leading to a coordinate singularity at some maximal value of the radial coordinate. Here we reconsidered the equation with an ansatz of the line element inspired from the literature about black strings (see e.g. [19]). It turns out that, with the new coordinates, the solutions can be continued up to $x = \infty$ and our numerical results suggest that the metric is of the Kasner-type asymptotically. This feature
seems to hold true for pure gravity black strings as well as for the non-abelian case. In the limit $x_h \to 0$ these two types of black strings approach a non trivial solution which is regular at the origin.
