Abstract

We construct a spinning closed string solution in $AdS_5 \times S^5$ which is folded in the radial direction and has two equal spins in $AdS_5$ and a spin in $S^5$. The energy expression of the three-spin solution specified by the folding and winding numbers for the small $S^5$ spin shows a logarithmic behavior and a one-third power behavior of the large total $AdS_5$ spin, in the long string and in the short string located near the boundary of $AdS_5$ respectively. It exhibits the non-regular expansion in the 't Hooft coupling constant, while it takes the regular one when the $S^5$ spin becomes large.
1 Introduction

The AdS/CFT correspondence \[1, 2, 3\] has been studied in the supergravity approximation. In order to verify the correspondence in its full extent it is desirable to go beyond the low energy supergravity approximation. Under the circumstance that it is hard to quantize the superstring theory in \(AdS_5 \times S^5\), the solvability of the string theory in the pp-wave background \[4, 5\] has opened a new step and led to an interesting proposal identifying particular stringy oscillator states with gauge invariant near-BPS operators with large R-charge in the BMN limit for the \(\mathcal{N} = 4\) SU(N) super Yang-Mills (SYM) theory \[6\]. This proposal has been interpreted as a special case of a semiclassical expansion of \(AdS_5 \times S^5\) string theory selecting a particular sector of states where the string shrinks to a point and moves with a large angular momentum along a large circle of \(S^5\) \[7\] and further developed \[8, 9, 10, 11, 12, 13, 14, 15, 16\]. A considerable amount of work has followed for various semiclassical string or membrane solutions \[17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29\].

Motivated by attempts to AdS/CFT correspondence to non-BPS states there have been the constructions of semiclassical string solutions with several angular momenta in different directions of \(AdS_5\) and \(S^5\). A novel solution describing a circular closed string rotating simultaneously in two planes in \(AdS_5\) with equal spins \(S\) has been shown to produce a large-spin expansion of the energy whose subleading term scales with spin as \(S^{1/3}\) instead of \(\log S\) in the one-spin solution, when the point-like string is located close to the boundary of \(AdS_5\) \[30\]. There have been the other solutions describing a circular closed string with three SO(6) angular momenta in \(S^5\) \[30, 31\] and a folded closed string with two SO(6) angular momenta \[32\] located at the origin of \(AdS_5\). A folded closed string solution with three spins \((J_1, J_2, J_3)\) in \(S^5\) has been constructed as a periodic solution of a Neumann one-dimensional integrable system \[33\], where the string is stretched along two angular directions and bent at one point. A three-spin string solution of circular type has been also analyzed and a two-spin one has been explicitly represented by the elliptic functions and a winding number. Their space-time energies expressed by the spins and the string tension \(\sqrt{\lambda}\) are arranged to take the regular expansions in the 't Hooft coupling constant \(\lambda\) and remarkably matched onto the associated scaling dimensions of the non-BPS operators obtained by analyzing the relevant Bethe equation for a spin chain model in the perturbative SYM theory \[34, 35, 32, 36, 38, 37, 38, 39\].

A hybrid \((S, J)\) state represented by a string rotating in one plane in \(S^5\) and having also one large spin in \(AdS_5\) has been shown to be analytically continued to the \((J_1, J_2)\) state represented by a folded string rotating in two planes in \(S^5\) \[37\]. A more general solution describing a string rotating in both \(AdS_5\) and \(S^5\) with constant radii has been constructed as a periodic solution of a Neumann-Rosochatius one-dimensional integrable system to be characterized by the \(2 + 3\) spins \((S_a, J_i)\) and the \(2 + 3\) winding numbers \[40\]. Its space-time energy has a regular large-spin expansion if there is at least one large spin in \(S^5\). There have been various investigations about the multi-spin string solutions and the gauge-string duality \[41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52\]. In ref. \[50\] a spinning solution folded in the radial direction with two equal spins in \(AdS_5\) has been presented, where the string is orbiting around the origin and the radius of string is not constant but oscillates between two locations. This solution specified by the folding and winding numbers associated with the
radial direction and an angular direction of $S^3$ within $AdS_5$ shows a logarithmic behavior of the energy-spin relation for the long string.

We will construct a folded three-spin solution which has not only the two equal spins in $AdS_5$ but also a spin in $S^5$ and is stretched along both the radial and angular directions. It will be shown how this hybrid three-spin solution interpolates between the two-spin solution with the logarithmic energy-spin relation for the long string and that with the $S^{1/3}$ relation for the point-like string.

2 Folded three-spin solutions

The bosonic part of the type IIB superstring action for the $AdS_5 \times S^5$ background is given by

$$I = -\frac{\sqrt{\lambda}}{4\pi} \int d^2\xi [G_{mn}^{(AdS_5)}(x)\partial_a x^m \partial^n x^n + G_{pq}^{(S^5)}(y)\partial_a y^p \partial^n y^n], \quad \sqrt{\lambda} \equiv \frac{R^2}{\alpha'},$$

where the $AdS_5 \times S^5$ metric in the global coordinates is expressed as

$$(ds^2)_{AdS_5} = d\rho^2 - \cosh^2 \rho dt^2 + \sinh^2 \rho (d\theta^2 + \cos^2 \theta d\phi_1^2 + \sin^2 \theta d\phi_2^2),$$

$$(ds^2)_{S^5} = d\gamma^2 + \cos^2 \gamma d\varphi_3^2 + \sin^2 \gamma (d\psi^2 + \cos^2 \psi d\varphi_1^2 + \sin^2 \psi d\varphi_2^2).$$

We consider a configuration that a closed string is spinning in the $\phi_1$ and $\phi_2$ directions of $AdS_5$ with equal spin as well as in the $\varphi_3$ direction of $S^5$, and stretched along the radial coordinate $\rho$ and along the angular coordinate $\theta$ of $S^5$. We make the following ansatz describing this configuration

$$t = \kappa \tau, \quad \phi_1 = \omega \tau, \quad \phi_2 = \omega \tau, \quad \varphi_3 = \nu \tau,$$

$$\rho = \rho(\sigma) = \rho(\sigma + 2\pi), \quad \theta = \theta(\sigma) = \theta(\sigma + 2\pi),$$

$$\gamma = \psi = \varphi_1 = \varphi_2 = 0.$$ 

The string equations of motion for $\theta$ and $\rho$ are given by

$$(\sinh^2 \rho \theta')' = 0, \quad \rho'' - \sinh \rho \cosh \rho (\kappa^2 + \theta^2 - \omega^2) = 0,$$

which lead to

$$\theta' = \frac{c}{\sinh^2 \rho}, \quad c = \text{const},$$

$$\rho'' - \frac{c^2 \cosh \rho}{\sinh^3 \rho} - \frac{1}{2} (\kappa^2 - \omega^2) \sinh 2\rho = 0.$$ 

The conformal gauge constraint is described by

$$\rho^2 = \kappa^2 \cosh^2 \rho - \frac{c^2}{\sinh^2 \rho} - \omega^2 \sinh^2 \rho - \nu^2,$$

which is also the first integral of (6) with an appropriate integral constant. In terms of $x = \cosh \rho$ it can be rewritten by

$$x'^2 = (\omega^2 - \kappa^2)(a_+ - x^2)(x^2 - a_-),$$

$$x^2 = (\omega^2 - \kappa^2)(a_+ - x^2)(x^2 - a_-),$$

$3$
where the constants $a_{\pm}$ are
\[ a_{\pm} = \frac{1}{2(\omega^2 - \kappa^2)} [2\omega^2 - \kappa^2 + \nu^2 \pm \sqrt{\kappa^4 + 2(2\omega^2 - \nu^2)\kappa^2 + \nu^4 - 4\omega^2\nu^2}] . \]  
(9)

We impose a condition
\[ 1 \leq a_- < a_+ \]  
(10)
so that the string has two different turning points $a_+, a_-$ in the radial direction. The integral of motion $c$ and the parameter $\kappa$ that is associated with the energy of the system, are described in terms of the turning points $a_+, a_-$ as
\[ c^2 = (\omega^2 - \kappa^2)(a_+ - 1)(a_- - 1) , \]  
(11)
\[ \kappa^2 = \omega^2 - \frac{\omega^2 - \nu^2}{a_+ + a_- - 1} , \]  
(12)
which imply that the condition (10) yields $\nu < \kappa < \omega$. Therefore it follows that $a_- = 1$ for $c = 0$.

We choose a differential equation $x' = -[(\omega^2 - \kappa^2)(a_+ - x^2)(x^2 - a_-)]^{1/2}$ for (8), which is transformed through the change of variables $x/\sqrt{a_+} = y, \sqrt{a_+}\omega^2 - \kappa^2)\sigma = u$ into
\[ \frac{d}{du}y(u) = -\sqrt{(1 - y^2) \left( y^2 - \frac{a_-}{a_+} \right)} . \]  
(13)

This expression yields a solution expressed by the Jacobi elliptic function
\[ \cosh \rho = \sqrt{a_+} \text{dn}(\sqrt{a_+}(\omega^2 - \kappa^2)\sigma, m) , \]
\[ = \left( a_+ - (a_+ - a_-)\text{sn}^2(\sqrt{a_+}(\omega^2 - \kappa^2)\sigma, m) \right)^{1/2} , \quad m = \frac{a_+ - a_-}{a_+} . \]  
(14)

When $a_{\pm}$ are parametrized as $a_{\pm} = \cosh^2 \rho_{\pm}$, from this expression we see that $\rho$ indeed oscillates between $\rho_+$ and $\rho_-$. The periodicity condition $\rho(\sigma) = \rho(\sigma + 2\pi)$ is expressed in terms of a folding number $N$ as
\[ \frac{2\pi}{N} \sqrt{a_+}(\omega^2 - \kappa^2) = 2K(m) \]  
(15)
since $\text{dn}(u)$ and $\text{sn}^2(u)$ in (14) have a fundamental period $2K$ where $K$ is the complete elliptic integral of the first kind. In this string configuration composed of $2N$ segments $\rho$ starts at $\rho_+$ and becomes $\rho_-$ as $\sigma$ goes from 0 to $\pi/N$ for one segment. Alternatively the periodicity condition (15) can be derived by the direct integration of (8) as
\[ \int_0^{2\pi} d\sigma = 2N \int_{\sqrt{a_+}}^{\sqrt{a_-}} dx \frac{-1}{\sqrt{(\omega^2 - \kappa^2)(a_+ - x^2)(x^2 - a_-)}} . \]  
(16)

Substituting the solution (14) into (5) and integrating we have
\[ \theta(\sigma) = \sqrt{\frac{a_- - 1}{a_+(a_+ - 1)}} \Pi \left( \sqrt{\frac{a_+}{a_+}(\omega^2 - \kappa^2)\sigma, \frac{a_+}{a_+ - 1} m} , \quad m = \frac{a_+ - a_-}{a_+} , \right) \]  
(17)
where $\Pi(u, n, m)$ is the elliptic integral of the third kind and we have chosen an integration constant such that $\theta(0) = 0$. From the periodicity condition $\theta(2\pi) = \theta(0) + 2\pi M$ for the angular coordinate the winding number $M$ is specified as

$$2\pi M = N\theta\left(\frac{2\pi}{N}\right) = N\theta\left(\frac{\pi}{N}\right),$$

(18)

which combines with (17) and (15) to yield

$$\frac{M}{\pi} = \sqrt{\frac{a_- - 1}{a_+ (a_+ - 1)}} \Pi\left(\frac{a_+ - a_-}{a_+ - 1}, m\right),$$

(19)

where $\Pi(n, m) \equiv \Pi(K, n, m)$. Alternatively it follows from the direct integration of (5) together with (8)

$$\int_{0}^{2\pi M} d\theta = 2N \int_{\sqrt{a_+}}^{\sqrt{a_-}} d\rho \frac{1}{\sqrt{(\omega^2 - \kappa^2)(a_+ - x^2)(x^2 - a_-) x^2 - 1}}.$$  

(20)

The integers $N, M$ will label different spinning configurations.

### 3 Energy-spin relations

The energy and three spins of spinning string solution are given by

$$E = \sqrt{\lambda \kappa} \int_{0}^{2\pi} \frac{d\sigma}{2\pi} \cosh^2 \rho \equiv \sqrt{\lambda} \mathcal{E}, \quad J = \sqrt{\lambda} \nu,$$

$$S_1 = \sqrt{\lambda \omega} \int_{0}^{2\pi} \frac{d\sigma}{2\pi} \sinh^2 \rho \cos^2 \theta \equiv \sqrt{\lambda} S_1,$$

$$S_2 = \sqrt{\lambda \omega} \int_{0}^{2\pi} \frac{d\sigma}{2\pi} \sinh^2 \rho \sin^2 \theta \equiv \sqrt{\lambda} S_2,$$

(21)

where $J, S_1$ and $S_2$ are the spins coming from the rotations in the $\varphi_3, \phi_1$ and $\phi_2$ directions, respectively. There is a relation between them

$$\frac{\mathcal{E}}{\kappa} - \frac{S}{\omega} = 1, \quad S \equiv S_1 + S_2.$$

(22)

In view of (16) the energy is computed as

$$\mathcal{E} = 2N\kappa \int_{\sqrt{a_+}}^{\sqrt{a_-}} \frac{dx}{2\pi} \frac{-x^2}{\sqrt{(\omega^2 - \kappa^2)(a_+ - x^2)(x^2 - a_-)}} = \frac{N\kappa \sqrt{a_+}}{\pi \sqrt{\omega^2 - \kappa^2}} E(m),$$

(23)

where $E(m)$ is the complete elliptic integral of the second kind. The substitution of $\kappa$ in (12) into (23) provides

$$\mathcal{E} = \frac{N \sqrt{a_+}}{\pi} \left(\frac{\nu^2 + \omega^2 (a_+ + a_- - 2)}{\omega^2 - \nu^2}\right)^{1/2} E(m).$$

(24)
From (15) and (12), the angular velocity parameter $\omega$ is given by

$$\omega = \left( \nu^2 + \frac{a_+ + a_- - 1}{\pi^2 a_+} K(m)^2 N^2 \right)^{1/2}.$$  \hspace{1cm} (25)

so that the energy expression (24) is expressed as

$$E = \frac{a_+ E}{K} \left( \nu^2 + \frac{a_+ + a_- - 2}{\pi^2 a_+} K^2 N^2 \right)^{1/2}.$$  \hspace{1cm} (26)

On the other hand we use (25) and (12) to rewrite the relation (22) as

$$E = \left( 1 + \frac{S}{\sqrt{\nu^2 + \frac{a_+ + a_- - 1}{\pi^2 a_+} K^2 N^2}} \right) \left( \nu^2 + \frac{a_+ + a_- - 2}{\pi^2 a_+} K^2 N^2 \right)^{1/2}.$$  \hspace{1cm} (27)

The comparison between (26) and (27) yields the total $AdS_5$ spin

$$S = \left( \frac{a_+ E}{K} - 1 \right) \left( \nu^2 + \frac{a_+ + a_- - 1}{\pi^2 a_+} K^2 N^2 \right)^{1/2}.$$  \hspace{1cm} (28)

In order to analyze the above equations it is convenient to use two parameters $m = (a_+ - a_-)/a_+$, $n = (a_+ - a_-)/(a_+ - 1)$ instead of the turning points $a_+, a_-$. Thus from (26), (28) and (19) we have the following three equations

$$E = \frac{n E(m)}{n - m} \left( \frac{\nu^2}{K(m)^2} + \frac{m(2 - n)}{\pi^2 n} N^2 \right)^{1/2},$$  \hspace{1cm} (29)

$$S = \frac{(n E(m))}{n - m} - K(m) \left( \frac{\nu^2}{K(m)^2} + \frac{n + m - nm}{\pi^2 n} N^2 \right)^{1/2},$$  \hspace{1cm} (30)

$$\frac{\pi M}{N} = \sqrt{\frac{(1 - n)(n - m)}{n}} \Pi(n, m),$$  \hspace{1cm} (31)

which are expressed in terms of the auxiliary two independent parameters $m, n$ so that if $m, n$ are eliminated from the three transcendental equations, the energy $E$ is in principle derived as a function of $S, J, M$ and $N$. The relation (24) is also expressed in terms of $m, n$ as

$$E = \left( 1 + \frac{S}{\sqrt{\nu^2 + \frac{n + m - nm}{\pi^2 n} K(m)^2 N^2}} \right) \left( \nu^2 + \frac{m(2 - n)}{\pi^2 n} K(m)^2 N^2 \right)^{1/2}.$$  \hspace{1cm} (32)

Now we are ready to extract explicit analytic expressions of energy-spin relations in several special regions specified by $J$ or $S \gg \sqrt{\lambda}$ and $J$ or $S \ll \sqrt{\lambda}$. The condition (10) is translated into $0 < m < n \leq 1$. The turning points $\rho_+, \rho_-$ are written in terms of $m, n$ as

$$\cosh^2 \rho_+ = \frac{n}{n - m}, \quad \cosh^2 \rho_- = \frac{n(1 - m)}{n - m}.$$  \hspace{1cm} (33)
In view of \( \cosh^2 \rho_+ - \cosh^2 \rho_- = m/(1 - \frac{m}{n}) \), a parameter region \( n \approx m \approx 1 \) corresponds to the long string, while a region specified by \( m/n \ll 1 \) and \( m \ll 1 \) to the short string. There is the other interesting short string region \( n \approx m \ll 1 - \frac{m}{n} \approx 1 \).

We start to consider the long string case and write down a formula

\[
\Pi(n, m) = K(m) + 2\sqrt{1 - k'^2 \sin^2 \psi} \left( \frac{1}{2} - \sin^{-1} \sqrt{\frac{1 - n}{1 - m}} \right),
\]

(34)

where \( k'^2 = 1 - m, n = 1 - k'^2 \sin^2 \psi \), and \( F(\psi, k'^2) \) and \( E(\psi, k'^2) \) are the elliptic integrals of the first and second kind respectively. For \( n \approx m \approx 1 \) it approximately reduces to

\[
\sqrt{\frac{1 - n}{1 - m}} \approx \cos \frac{M N \pi}{n}.
\]

(36)

We can now use (36) to rewrite (29) and (30) as

\[
E \approx \left( \frac{\nu^2}{K^2} + \frac{N^2}{\pi^2} \right)^{1/2} \frac{1}{(1 - m) \sin^2 \left( \frac{M N \pi}{n} \right)} \left( 1 + \frac{1 - m}{2} \log \frac{16}{1 - m} \right),
\]

(37)

\[
S \approx \left( \frac{\nu^2}{K^2} + \frac{N^2}{\pi^2} \right)^{1/2} \frac{1}{(1 - m) \sin^2 \left( \frac{M N \pi}{n} \right)} \left[ 1 + \frac{1 - m}{2} \left( 1 - \sin^2 \left( \frac{M N \pi}{n} \right) \right) \log \frac{16}{1 - m} \right]
\]

(38)

with \( K(m) \approx \frac{1}{2} \log \frac{16}{1 - m} \). Their difference gives

\[
E - S \approx \frac{1}{2} \left( \frac{\nu^2}{K^2} + \frac{N^2}{\pi^2} \right)^{1/2} \log \frac{16}{1 - m}.
\]

(39)

For the region \( \nu/\log(\frac{1}{1-m}) \ll 1 \), the large total spin \( S \) is approximately estimated as

\[
S \approx \frac{N/\pi}{(1 - m) \sin^2 \left( \frac{M N \pi}{n} \right)}
\]

(40)

so that we have a logarithmic scaling behavior

\[
E - S \approx \frac{N}{2\pi} \log \pi S + \frac{\pi \nu^2}{N \log \pi S} + \ldots.
\]

(41)

Restoring the \( \lambda \)-dependence provides

\[
E - S \approx \frac{N \sqrt{\lambda}}{2\pi} \log \frac{\pi S}{\sqrt{\lambda}} + \frac{\pi J^2}{N \sqrt{\lambda} \log \frac{\pi S}{\sqrt{\lambda}}} + \ldots, \quad \frac{S}{\sqrt{\lambda}} \gg 1, \quad \frac{J}{\sqrt{\lambda}} \ll \log \frac{S}{\sqrt{\lambda}},
\]

(42)
which shows a semiclassical $\sqrt{\lambda}$ expansion for the energy-spin relation. When $J = 0$ this expression reduces to the result of ref. [50].

For the opposite region $\nu/\log(\frac{1}{1-m}) \gg 1$, we have an approximate relation $\log(\mathcal{S}/\nu) \approx \log(1/(1-m))$, which yields

$$\mathcal{E} - \mathcal{S} \approx \nu + \frac{N^2}{8\pi^2\nu} \log^2 \frac{\mathcal{S}}{\nu} + \cdots. \quad (43)$$

Thus we have a regular expansion in integer powers of $\lambda$

$$E - S \approx J + \frac{\lambda N^2}{8\pi^2 J} \log^2 \frac{S}{J} + \cdots, \quad \frac{S}{\sqrt{\lambda}} \gg 1, \quad \frac{J}{\sqrt{\lambda}} \gg \log \frac{S}{J}. \quad (44)$$

Now we analyze the short string region specified by $m \ll n \ll 1$ that is more restricted than $m \ll n < 1$. Eq. (31) is approximately given by

$$\frac{2M}{N} \approx \sqrt{1 - \frac{m}{n}}, \quad (45)$$

which is satisfied when $2M < N$. The radial location of short string is so specified by

$$\cosh^2 \rho_+ \approx \cosh^2 \rho_- \approx \left( \frac{N}{2M} \right)^2 \quad (46)$$

that the string is located near the origin of $AdS_5$.

For $\nu \ll 1$ from (30) the total spin $\mathcal{S}$ is approximately estimated to be a small value

$$\mathcal{S} \approx \frac{N m}{2} \ll 1 \quad (47)$$

and then the energy $\mathcal{E}$ in (29) is specified by

$$\mathcal{E}^2 \approx \nu^2 + S \mathcal{N}. \quad (48)$$

This expression becomes

$$E^2 \approx J^2 + \sqrt{\lambda} S \mathcal{N}, \quad \frac{S}{\sqrt{\lambda}} \ll 1, \quad \frac{J}{\sqrt{\lambda}} \ll 1, \quad (49)$$

which shows the usual Regge trajectory relation when $J = 0$. The energy-spin relations of three-spin ($S_1 = S_2, J$) solution [12], [14] and [19] for the respective parameter regions are similar to the analogous relations of the two-spin ($S, J$) solution [8, 9].

For $\nu \gg 1$ eq. (30) can be approximately expressed as

$$\mathcal{S} \approx \frac{m}{n-m} \left( \nu^2 + \frac{N^2}{4} \left( 1 + \frac{m}{n} \right) \right)^{1/2} \quad (50)$$

from which it is noted that $\mathcal{S} \ll \nu$. Taking advantage of $\mathcal{S} \ll \nu$ to use an iterative expansion method we can derive a solution of (50) in a large-spin expansion form as

$$\frac{m}{n} \approx \frac{\mathcal{S}}{\nu} - \left( \frac{\mathcal{S}}{\nu} \right)^2 - \frac{N^2 S}{8\nu^3} + \frac{N^2 S^2}{8\nu^4} + \cdots. \quad (51)$$
Substituting this solution into the energy expression \((32)\) instead of \((29)\) we have
\[
\mathcal{E} \approx \nu + S + \frac{N^2 S}{8\nu^2} - \frac{N^2 S^2}{8
\nu^3} + \cdots, \tag{52}
\]
which reads
\[
E \approx J + S + \frac{\lambda N^2 S}{8J^2} - \frac{\lambda N^2 S^2}{8J^3} + \cdots, \quad \frac{J}{\sqrt{\lambda}} \gg 1, \ J \gg S. \tag{53}
\]
The energy expression \((53)\) for the three-spin solution in a near BMN limit \(S/J \ll 1\) is compared with that for the two-spin \((S,J)\) solution \([8,9,37]\). Here we write down the energy of the two-spin solution including full dependence on \(\lambda\) presented in \([37]\)
\[
E = J + S + \frac{\lambda S}{2J} - \frac{\lambda S^2}{2J^2} + \cdots \tag{54}
\]
whose expansion in \(\lambda/J^2\)
\[
E \approx J + S + \frac{\lambda S}{2J^2} - \frac{\lambda S^2}{2J^3} + \cdots \tag{55}
\]
has a similar behavior to \((53)\). The analytic expansion in \(\lambda\) of \((53)\) is also compared with the non-analytic one of the energy for \((49)\).

Let us consider the parameter region \(n \approx m \ll 1 - \frac{m}{n} \ll 1\) where the string becomes short and its radial location takes a large value \(\cosh^2 \rho^2_n \approx \cosh^2 \rho^2_0 \approx 1/(1 - \frac{m}{n})\) so that the short string is close to the boundary of \(AdS_5\). In this region the ratio \(M/N\) is specified by
\[
2\frac{M}{N} \approx \sqrt{1 - \frac{m}{n}} \ll 1. \tag{56}
\]
For \(\nu \ll 1\) eq. \((30)\) is also expressed as \((50)\), from which it is noted that \(S \gg 1\). Therefore the solution of \((50)\) is approximately obtained by the iterative expansion procedure as
\[
\frac{m}{n} \approx 1 - \frac{N}{\sqrt{2N}} + \frac{5N^2}{8SN} - \frac{\nu^2}{2\sqrt{2NS}} + \cdots. \tag{57}
\]
Combining this expansion with the energy expression \((32)\), we derive
\[
\mathcal{E} = S + \frac{3\sqrt{2N}}{8} - \frac{11N^2}{64S} + \frac{3\sqrt{2\nu^2}}{4N} + \cdots, \tag{58}
\]
where the \(S\nu^2\) term has been canceled out. This expression yields a non-regular \(\lambda\) expansion
\[
E = S + \frac{3\sqrt{2\sqrt{\lambda}N}}{8} - \frac{11\lambda N^2}{64S} + \frac{3\sqrt{2J^2}}{4\sqrt{\lambda}N} + \cdots, \quad \frac{S}{\sqrt{\lambda}} \gg 1 \gg \frac{J}{\sqrt{\lambda}}. \tag{59}
\]
Here from \((56)\) \(N\) is much larger than \(M\), while \(N\) is the same order as \(M\) in \((49)\) and \((53)\) for the previous cases. In order to trade large integer \(N\) for small finite integer \(M\) we use \((56)\) and \((57)\) to have \(N \approx (2M)^{2/3}(\sqrt{2/\lambda S})^{1/3}\), whose substitution into \((59)\) for \(J = 0\) yields
\[
E = S + \frac{3}{4}(2M^2\lambda S)^{1/3} + \mathcal{O}(S^{-1/3}). \tag{60}
\]
In the energy of the circular constant-radii string solution with the large two spins $S_1, S_2$ in $AdS_5$ was presented as

$$E = S + \frac{3}{4} (\lambda S)^{1/3} \left( 2k_1^2 \frac{S_1}{S_2} \right)^{1/3} + \cdots,$$

(61)

where $k_1 S_1 + k_2 S_2 = 0, S = S_1 + S_2$ and $S_a \gg \sqrt{\lambda}$. When the two spins are equal, the two winding numbers $k_a$ satisfy $k_1 = -k_2$ and the regular $\lambda$ expansion (61) agrees with (60). Thus the short three-spin string with large $S$, when $J = 0$, corresponds to the circular point-like two-spin string located near the boundary of $AdS_5$.

For $\nu \gg 1$ the solution of (50) takes an expansion form

$$\frac{m}{n} \approx 1 - \nu + \left( \frac{\nu}{S} \right)^2 - \frac{N^2}{8S\nu} + \frac{5N^2}{8S^2} + \cdots$$

(62)

owing to $S \gg \nu$. The energy expression (32) together with (62) yields

$$E \approx S + \nu + \frac{N^2}{8\nu} - \frac{N^2}{8S} + \cdots,$$

(63)

where the $S/\nu^2$ term has been canceled out. Thus restoring the $\lambda$-dependence we have

$$E \approx S + J + \frac{\lambda N^2}{8J} - \frac{\lambda N^2}{8S} + \cdots, \quad \frac{S}{\sqrt{\lambda}} \gg \frac{J}{\sqrt{\lambda}} \gg 1,$$

(64)

which shows a regular $\lambda$ expansion. Using $N^2 \approx 4M^2S/J$ that is obtained from (55) and (62) we trade large integer $N$ for small finite integer $M$ to have

$$E = S + J + \frac{\lambda M^2 S}{2J^2} - \frac{\lambda M^2}{2J} + \cdots.$$ 

(65)

Its $\lambda$ dependence remains the same as (64), while the $\lambda^{1/2}$ dependence of the subleading term in (59) is changed into the $\lambda^{1/3}$ dependence of the corresponding term in (60).

4 Conclusion

Analyzing the conformal gauge constraint and the closed string periodicity conditions for both the radial and angular directions in $AdS_5$, we have constructed a solution describing a folded three-spin string with two equal spins in $AdS_5$ and a spin in $S^5$. This string is orbiting around the origin and its energy is a function of the total $AdS_5$ spin $S$, the $S^5$ spin $J$ and the folding and winding numbers as a parametric solution of the system of three transcendental equations.

We have observed that there exist three types of string configurations in certain limits; a long string with a large total spin $S$, a short string with a small $S$ located near the origin of $AdS_5$ and a short string with a large $S$ located near the boundary of $AdS_5$. By means of the iterative expansion method we have extracted the energy-spin relations for the short strings. For the large value of $S$ there appear two different configurations such as the long
string and the latter short string, whose energy expressions include the linear term of $S$ irrespective of the magnitude of $J$. The former short string is characterized by the folding and winding numbers $N,M$ with same order magnitude, while the latter short string by the small value of $M/N$. The long string as well as the former short string has been shown to produce the same energy-spin relations as the two-spin $(S,J)$ string, where a logarithmic behavior, a Regge-type one and a BMN-type one appear. We have demonstrated that the latter short string with $J = 0$ reproduces the energy-spin relation with a term $S^{1/3}$ for the two-spin string with two equal $AdS_5$ spins. We have observed that the energy expression for the latter short string with $S \gg \sqrt{\lambda} \gg J$ shows a non-regular $\lambda$ expansion, while that with $S \gg J \gg \sqrt{\lambda}$ is indeed arranged to take a regular $\lambda$ expansion. The non-perturbative $\lambda$ expansion for the small $S^5$ spin is changed into the perturbative $\lambda$ expansion for the large $S^5$ spin, which transition is also seen in the long string as well as the former short string. Thus the spin in $S^5$ should be large in order to have the regular $\lambda$ expansion for the energy of folded three-spin solution, which includes the leading linear term of $J$. It is desirable to derive these regular $\lambda$ expansions of the semiclassical string energy by computing the quantum anomalous dimension of the relevant gauge invariant operator including covariant derivatives from the SYM perturbation theory.
