Abstract. To investigate the accumulation characteristics and mechanism of melatonin in cherry leaves of different leaf ages, the melatonin content and the expression of synthetic genes in cherry leaves of different leaf ages were measured. The results showed that the highest melatonin content was found in young leaves of cherry. By analyzing the expression of genes for melatonin synthesis in leaves of different leaf ages, it was found that there was a good correlation between gene expression and melatonin content, and the trend was similar, both young leaves were higher than mature leaves and old leaves. By measuring the melatonin content in cherry leaves and the expression of genes for melatonin synthesis, this paper revealed the accumulation rule of melatonin in cherry leaves, and provided a reference for studying the characteristics of melatonin accumulation in plant leaves.

1 Introduction

Melatonin (N-acetyl-5-methoxytryptamine) is a newly discovered indoles hormone widely found in animals, plants and microorganisms. It is an amphiprotic molecules that can move in and out of cells freely and react with hydroxyl radicals and peroxides [1,2]. Studies on melatonin have found that it can effectively remove hydroxyl free radicals, peroxy free radicals, hydrogen peroxide, superoxide anion free radicals and singlet oxygen, and its antioxidant capacity is higher than that of carotenoids, glutathione, VC and VE [3]. There are few studies on the accumulation of melatonin in planting leaves.

In this study, the content of melatonin in leaves of different leaf ages of cherry was determined, and the expression of genes in melatonin synthesis was analyzed to investigate the relationship between melatonin accumulation and leaf ages of cherry leaves, as well as the gene expression rules of melatonin synthesis in leaves of different leaf ages.

2 Materials and methods

2.1 Material preparation and handling

2.1.1 Collect leaves

When the cherries are ripe, young leaves, mature leaves and old leaves were collected and put into an ice box. A total of 3 sets of leaves were collected, of which 60 pieces were collected as a group (10 pieces per set, 6 in total), and immediately sent to the laboratory for packaging, quick-frozen with liquid nitrogen, stored in the refrigerator at -80°C, the content of melatonin was determined, and RNA was extracted.

2.2 Melatonin content determination

High performance liquid chromatography-fluorescence assay was used. The 0.5g leaves were ground into homogenate in 5ml methanol without light. Then it was extracted by 200W ultrasonic oscillation for 30min and centrifuged at 10000r /min for 15min. The supernatant was taken 2ml, filtered with 0.22um organic filter membrane for chromatographic analysis. The samples were separated on a nertil ODS-3C18 column (4.6×250mm) with mobile phase (Water: methanol: acetic acid =44.9:55:0.1) at a flow rate of 0.8ml min-1. Melatonin was detected at 280nm excitation and 384nm emission wavelengths.

2.3 Gene expression

The expression patterns of five genes involved in melatonin synthesis, including TDC, TSH1, TSH2, SNAT and ASMT were investigated by qRT-PCR. The primers were design using Primer3 based on our transcription data. Total RNA was extracted from samples according to the instructions of RNA prep pure Plant Kit. The concentration of total RNA samples was detected by nucleic acid protein analyzer, and the integrity was detected by 1.2% gel electrophoresis.

According to the instructions of the Prime Script™ Reverse Transcriptase Kit, total RNA was used as a template for Reverse transcription into cDNA. After the mixing centrifugation, reverse transcription was performed on a PCR instrument (37 °C for 15 minutes, 85 °C for 5 seconds), then centrifugation was performed. The samples were diluted 10 times and the concentration of RT products was determined by Nnd-2000C nucleic acid protein detector. According to the results, all RT products were diluted to the same concentration for PCR amplification.

Table 1. Primers used in this study.

| Primer         | Sequence                                      |
|----------------|-----------------------------------------------|
| PacTDC-real    | AACCGGAAGGATTITTGCTT CACATGCTCTCCTCAGTCA      |
| PacT3H1-real   | CAAAGCAATTCTGCAGGACA TTGGTGAAGTCGCTTCCTT      |
| PacT3H2-real   | CAAAATGCACTCGACAGAGA ACCCTGGCACTACCAATCTG     |
| PacSNAT-real   | GATCAAGGGGAATGGACAA GCCCTGATACCCAGATCAA       |
| PacASMT-real   | GATGAGCCTAGCTCCAATGC GCCCAAAGTCTGAAATCTCAA    |
| Actin          | CTTGCATCCCTCAGCACCTT TCCTTGGAACATAAGTGAAGGA   |

Primers for the expression analysis of four genes were designed based on the sequences of the genes cloned by the research group. By reverse transcription of cDNA template, reference SYBR @ Premix Ex Taq™ II kit instructions operate (reaction system for SYBR Premix Ex Taq™ 10.0 μL, primers respectively 0.4 μL, ddH2O 8.2 μL). PCR amplification was performed using BIO-RAD iQ5™ real-time quantitative PCR instrument. The reaction procedure was: pre-denaturation at 95°C for 10min; Denatured at 95°C for 10s; Annealing at 60°C for 31s and 72°C extension 20s, a total of 40 cycles. iQ5™ real-time PCR Detection System was used to analyze gene expression data.

2.4 Data processing and analysis

Test data were processed and analyzed by Excel 2016.

3 Results and analysis

3.1. Changes of melatonin content in leaves at different leaf ages

The melatonin (MT) content in leaves of Chinese cherry at different leaf ages was compared (figure 1). The melatonin content was as follows: young leaves > mature leaves > old leaves. The content of melatonin in young leaves was about 2.48ug/g, twice that in mature leaves and 3.6 times that in older leaves.

![Figure 1. The content of melatonin in cherry leaves with different leaf ages.](https://doi.org/10.1051/e3sconf/202014501019)
4 Conclusion

The content of melatonin in leaves of different leaf ages is different, and the difference is large, mainly manifested as: young leaves > mature leaves > old leaves. Studies have found that melatonin levels in the mulberry leaves are characterized by: young leaves > mature leaves > old leaves [4], this is consistent with the test results, it shows that the accumulation pattern of melatonin in the blade is likely to be young leaves > mature leaves > old leaves, predecessors also think melatonin is a kind of juvenile or aging antagonist material [5]. The experimental material is only for Chinese cherry leaves, and the peculiar accumulation rule of melatonin at different leaf ages needs to be studied. In the analysis of the expression of genes for melatonin synthesis in leaves of different ages of Chinese cherries, it was found that the expression of five genes in leaves was consistent with the change trend of melatonin content, all of which were young leaves > mature leaves and old leaves. We found that although melatonin content was lower in old leaves than in mature leaves. The melatonin-related gene expression was higher in old leaves. In addition, in the current studies, the expression of PacTDC gene was prior to the synthesis of melatonin [6], both in fruit development and 24-hour rhythm studies. Although the expression level of PacTDC gene was not the highest in this experiment, it also played an important role in the synthesis of melatonin. It was found that the expression level of PacT5H1 was the highest in young leaves, and the expression level of PacSNAT was the highest in mature leaves and old leaves. Therefore, it is speculated that the expression of PacT5H1 plays a greater role in the synthesis of melatonin during the growth period of leaves. After the ripening of leaves, the expression levels of melatonin synthesis related genes were significantly decreased, and the expression of PacSNAT played a more significant role in melatonin synthesis. With the aging of mature leaves, in order to delay the aging of leaves, the expression level of genes related to melatonin synthesis increased slightly, but was still lower than that in young leaves, and the expression level of PacSNAT was still the highest. Studies have found that melatonin's effects in plants include protecting young tissues and delaying plant senescence [5]. Therefore, it can be believed that the main purpose of plant melatonin synthesis in young leaves is to avoid oxidative damage and protect young tissues, during which a relatively large amount of melatonin is synthesized. In the old leaves, the enzyme activity gradually decreased with the senescence of the leaves, and the gene expression level should be lower than that of the mature leaves and the young leaves. However, in order to delay senescence, the expression level of the gene for melatonin synthesis began to increase, which was higher than that of the mature leaves. However, at the same time, melatonin content was lower than that of mature leaves due to the decreased enzyme activity. This study provides a certain reference for the study of melatonin accumulation in plants, especially cherry leaves, and provides a new direction for the study of the expression of genes for melatonin synthesis.
