Abstract

We report the results of a study of the exclusive semileptonic decays $B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell$, $\bar{B}^0 \rightarrow \pi^0 \ell^- \bar{\nu}_\ell$, $B^- \rightarrow \rho^0 \ell^- \bar{\nu}_\ell$, $\bar{B}^0 \rightarrow \rho^0 \ell^- \bar{\nu}_\ell$ and $B^- \rightarrow \omega \ell^- \bar{\nu}_\ell$, where $\ell$ represents an electron or a muon. The events are tagged by fully reconstructing a second $B$ meson in the event in a hadronic decay mode. The measured branching fractions are $\mathcal{B}(B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell) = (0.80 \pm 0.08 \pm 0.04) \times 10^{-4}$, $\mathcal{B}(\bar{B}^0 \rightarrow \pi^0 \ell^- \bar{\nu}_\ell) = (1.49 \pm 0.09 \pm 0.07) \times 10^{-4}$, $\mathcal{B}(B^- \rightarrow \rho^0 \ell^- \bar{\nu}_\ell) = (1.83 \pm 0.10 \pm 0.10) \times 10^{-4}$, $\mathcal{B}(\bar{B}^0 \rightarrow \rho^0 \ell^- \bar{\nu}_\ell) = (3.22 \pm 0.27 \pm 0.24) \times 10^{-4}$, and $\mathcal{B}(B^- \rightarrow \omega \ell^- \bar{\nu}_\ell) = (1.07 \pm 0.16 \pm 0.07) \times 10^{-4}$, where the first error is statistical and the second one is systematic. The obtained branching fractions are inclusive of soft photon emission. We also determine the branching fractions as a function of the 4-momentum transfer squared to the leptonic system $q^2 = (p_\ell + p_\nu)^2$, where $p_\ell$ and $p_\nu$ are the lepton and neutrino 4-momenta, respectively. Using the pion modes, a recent LCSR calculation, lattice QCD results and a model-independent description of the hadronic form factor, a value of the CKM matrix element $|V_{ub}| = (3.52 \pm 0.29) \times 10^{-3}$ is extracted. For the first time, a charmless state with invariant mass greater than 1 GeV/$c^2$, which might be dominated by the decay $B^- \rightarrow f_2 \ell^- \bar{\nu}_\ell$, is observed. These results are obtained from a 711 fb$^{-1}$ data sample that contains $772 \times 10^6 B\bar{B}$ pairs, collected near the $\Upsilon(4S)$ resonance with the Belle detector at the KEKB asymmetric-energy $e^+e^-$ collider.

I. INTRODUCTION

The Standard Model (SM) of particle physics contains a number of parameters whose values are not predicted by theory and must therefore be measured by experiment. In the quark sector, the elements of the Cabibbo-Kobayashi-Maskawa (CKM) matrix [1] determine the rates of the weak transitions between quark flavours, and precision measurements of their values are desirable. In particular, in the context of $B$-meson decays, there is currently much experimental and theoretical effort to test the consistency of the well-known CKM unitarity triangle (UT).

The UT angle $\phi_1$ [2], characterising indirect $CP$ violation in $b \to c\bar{c}s$ transitions, was first observed to be non-zero in 2001 [3], and $\sin 2\phi_1$ is now known to a precision of better than 3% [4]. This makes a corresponding precision measurement of the length of the side of the unitarity triangle opposite $\phi_1$ particularly important as a consistency check of the SM picture. The length of this side is determined to good approximation by the ratio of the magnitudes of two CKM matrix elements, $|V_{ub}/V_{cb}|$. Both can be measured using exclusive semileptonic $B$-meson decays. Using charmed semileptonic decays, the precision to which $|V_{cb}|$ has been determined is 2-3% [5]. In comparison, $|V_{ub}|$, which can be measured using charmless semileptonic decays, is poorly known. Both inclusive and exclusive methods of measuring $|V_{ub}|$ have been pursued, with the results of the two approaches being in some tension [6]. It is the aim of an ongoing programme at the $B$ factories to improve the precision of these measurements, in order to provide a more stringent comparison of exclusive and inclusive results, which have somewhat different experimental and theoretical uncertainties, and to provide a sharp consistency test with the value of $\sin 2\phi_1$.

Measurements of branching fractions for exclusive $\bar{B} \to X_u \ell^- \bar{\nu}_\ell$ decays, where $X_u$ denotes a light meson containing a $u$ quark and $\ell$ an electron or muon, have been reported by the CLEO [7], BABAR [8–12] and Belle [13–15] collaborations. Three methods of identifying signal candidates have been employed in these studies. In untagged analyses, the missing energy and momentum of the whole event are used to reconstruct the neutrino from the signal semileptonic decay. Semileptonic tagging involves partial reconstruction of a $B \to D^{(*)}\ell\nu$ decay as the tagging mode. In this case, two neutrinos are present in the event and the kinematics cannot be fully constrained. In full reconstruction tagging, a hadronically decaying $B$ meson is reconstructed, against which the signal decay recoils.

In this article, we present measurements of the total and partial branching fractions for the exclusive semileptonic decays $\bar{B}^0 \to \pi^+\ell^-\bar{\nu}_\ell$, $B^- \to \pi^0\ell^-\bar{\nu}_\ell$, $\bar{B}^0 \to \rho^+\ell^-\bar{\nu}_\ell$, $B^- \to \rho^0\ell^-\bar{\nu}_\ell$ and $B^- \to \omega\ell^-\bar{\nu}_\ell$ [16] using the full reconstruction tagging technique. The measurement is based on a 711 fb$^{-1}$ data sample that contains $(772 \pm 11) \times 10^6$ $B\bar{B}$ pairs, collected with the Belle detector at the KEKB asymmetric-energy $e^+e^-$ (3.5 on 8 GeV) collider [17] operating at the $\Upsilon(4S)$ resonance.

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF) and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL) located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux-return yoke located outside of the coil is instrumented to detect $K_L^0$ mesons and to identify muons (KLM). The detector is described in detail elsewhere [18]. Two inner detector configurations were used. A 2.0 cm beampipe and a 3-layer silicon vertex detector were used for the first sample of $152 \times 10^6$ $B\bar{B}$ pairs, while a 1.5 cm beampipe, a 4-layer silicon detector and a
small-cell inner drift chamber were used to record the remaining $620 \times 10^6 \, B\bar{B}$ pairs [19].

Recently, a new reconstruction procedure for $B$-meson hadronic decays based on the NeuroBayes neural network package [20] has been introduced in Belle. This procedure reconstructs $B$ mesons in more than 1100 exclusive hadronic decay channels. Compared to the previous cut-based algorithm, it offers roughly a factor of two efficiency gain and about $2.1 \times 10^6 \, (1.4 \times 10^6)$ fully reconstructed charged (neutral) $B$-meson decays within the data sample collected at the $\Upsilon(4S)$ resonance.

II. DIFFERENTIAL DECAY RATES

The decay rate for the process $B \to f_1 f_2 \ldots$, where the $f_i$ represent final state particles, is given by

$$d\Gamma(B \to f_1 f_2 \ldots) = \frac{1}{2m_B} |\mathcal{M}(B \to f_1 f_2 \ldots)|^2 d\Pi,$$

where $m_B$ is the mass of the $B$ meson, $\mathcal{M}$ is the matrix element for the decay,

$$d\Pi = (2\pi)^4 \delta^{(4)}(p_B - \sum_i p_i) \prod_i \frac{d^3p_i}{(2\pi)^3 2E_i}$$

is the total decay phase space element, $p_B$ is the 4-vector of the parent $B$ meson and $p_i = (E_i, \vec{p}_i)$ are the 4-vectors of the final state particles $f_i$.

The matrix element for weak semileptonic $B$-meson decays at first order can be written as

$$\mathcal{M}(\bar{B} \to X_q \ell^{-}\bar{\nu}_\ell) = \frac{G_F}{\sqrt{2}} V_{qb} L^\mu H^\mu,$$

where $G_F$ is the Fermi constant, $V_{qb}$ is the element of the CKM matrix corresponding to the $b \to q$ transition, $L^\mu = \bar{u}_\ell \gamma^\mu (1 - \gamma^5) v_\nu$ is the leptonic current and $H^\mu$ is the hadronic current, which depends on the particular hadronic final state. More details about the subsequent formulae can be found elsewhere [21].

A. The $\bar{B} \to \pi \ell^{-}\bar{\nu}_\ell$ decay

We can parametrise the hadronic current for the $\bar{B} \to \pi \ell^{-}\bar{\nu}_\ell$ decay as

$$H_\mu = \langle \pi(p_\pi)|V_\mu|B(p_B)\rangle = f_+(q^2) \left( p_B + p_\pi - q \frac{m_B^2 - m_\pi^2}{q^2} \right)_\mu + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q_\mu,$$

where $q = p_B - p_\pi = p_W = p_\ell + p_\nu$ is the 4-momentum transferred to the leptonic system, $f_+(q^2)$ is a vector form factor, and $f_0(q^2)$ is a scalar form factor; we use $f_+(0) \equiv f_0(0)$ to avoid a kinematic singularity at $q^2 = 0$.

The differential decay rate for the process involving pseudoscalar mesons is written as

$$\frac{d\Gamma}{dq^2}(\bar{B} \to \pi \ell^{-}\bar{\nu}_\ell) = \frac{G_F^2 |V_{ub}|^2}{24\pi^3 m_B^2 q^2} (q^2 - m_\pi^2)^2 |\bar{p}_\pi|^2 \times$$

$$\left[ \left( 1 + \frac{m_\pi^2}{2q^2} \right) m_B^2 |\bar{p}_\pi|^2 \left| f_+(q^2) \right|^2 + \frac{3m_\pi^2}{8q^2} \left( m_B^2 - m_\pi^2 \right)^2 \left| f_0(q^2) \right|^2 \right],$$

(5)
where \(|\vec{p}_\pi|\) is the magnitude of the pion momentum in the \(B\) rest frame. For light leptons (\(e\) and \(\mu\)), we can neglect terms proportional to \(m^2\) so that only \(f_+(q^2)\) is relevant:

\[
\frac{d\Gamma}{dq^2} = \frac{G_F^2}{24\pi^3} |V_{ub}|^2 |f_+(q^2)|^2 |\vec{p}_\pi|^3. \tag{6}
\]

B. The \(\bar{B} \to \rho \ell^- \bar{\nu}_\ell\) and \(B^- \to \omega \ell^- \bar{\nu}_\ell\) decays

For semileptonic decays with vector mesons in the final state, \(i.e.,\) \(\rho\) or \(\omega\), we can define the hadronic current with four dimensionless form factors:

\[
H_\mu = \langle V(p) | (V - A)_\mu | B(p_B) \rangle = -ie^* (m_B + m_V) A_1^V(q^2) + i(p_B + p)_\mu (e^* p_B) \frac{A_2^V(q^2)}{m_B + m_V}
+ iq_\mu (e^* p_B) \frac{2m_V}{q^2} (A_3^V(q^2) - A_0^V(q^2)) + \epsilon_{\mu\nu\rho\sigma} e^* p_B^\rho \frac{2V^V(q^2)}{m_B + m_V}, \tag{7}
\]

with the exact relations among the form factors

\[
A_3^V(q^2) = \frac{m_B + m_V}{2m_V} A_1^V(q^2) - \frac{m_B - m_V}{2m_V} A_2^V(q^2), \tag{8}
\]
\[
A_0^V(0) = A_0^V(q^2), \tag{9}
\]
\[
\langle V|\partial_\mu A^\mu|B\rangle = 2m_V (e^* p_B) A_0^V(q^2), \tag{10}
\]

where \(V\) represents a \(\rho\) or \(\omega\) meson, \(p_B\) is the 4-momentum of the \(B\) meson, and \(p, e^*\) and \(m_V\) are the 4-momentum, polarization 4-vector and mass of the vector meson, respectively. Again, for light leptons (\(e\) and \(\mu\)), the term proportional to \(q_\mu^2\) is negligible so that, in effect, the decay rate depends only on the form factors \(A_1(q^2), A_2(q^2)\) and \(V(q^2)\).

In the case \(\bar{B} \to \rho \ell^- \bar{\nu}_\ell\) where the \(\rho\)-meson decays into two pions \(\rho \to \pi\pi\), the fully differential decay rate in the helicity basis is:

\[
\frac{d\Gamma}{dq^2 \cos \theta_\ell \cos \theta_V \ d\chi \ dm_V} = \frac{3}{8(4\pi)^4} \frac{G_F^2 |V_{ub}|^2 |\vec{p}_V|^2}{m_B^2} |\text{BW}(m_V)|^2 \times \left[ (1 - \eta \cos \theta_\ell)^2 \sin^2 \theta_V |H_+(q^2, m_V)|^2 
+ (1 + \eta \cos \theta_\ell)^2 \sin^2 \theta_V |H_-(q^2, m_V)|^2 + 4 \sin^2 \theta_\ell \cos \theta_\ell |H_0(q^2, m_V)|^2
- 4 \eta \sin \theta_\ell \sin \theta_V \cos \theta_\ell \cos \theta_V \cos \chi H_0(q^2, m_V) \times ((1 - \eta \cos \theta_\ell) H_+(q^2, m_V) 
+ (1 + \eta \cos \theta_\ell) H_-(q^2, m_V) - 2 \sin^2 \theta_\ell \sin^2 \theta_V \cos 2\chi H_+(q^2, m_V) H_-(q^2, m_V) \right], \tag{11}
\]

where \(\text{BW}(m_V)\) represents the resonance line shape, \(m_V\) is the invariant mass of the recoiling hadron, \(|\vec{p}_V|\) is the magnitude of the vector meson momentum in the \(B\) meson rest frame, \(\theta_\ell\) is the polar angle of the lepton in the \(W\) rest frame with respect to the \(W\) flight direction in the \(B\) rest frame, \(\theta_V\) is the polar angle of one of the pseudoscalar daughters in the rest frame of the vector meson with respect to the vector meson flight direction in the \(B\) rest frame, and \(\chi\) is the angle between the decay planes of the \(W\) boson and the vector meson. The factor \(\eta\) is equal to +1 for semileptonic \(\bar{B}\)-meson decays.
The differential decay rate for $B^{-} \rightarrow \omega \ell^{-} \bar{\nu}_{\ell}$, integrated over angular variables, is

$$
\frac{d\Gamma}{dq^{2}dm_{\ell\nu}} = \frac{1}{96\pi^{3}}G_{F}^{2}|V_{ub}|^{2}m_{B}^{2}|\vec{p}_{V}|^{2}BW(m_{\nu})|2 \times \left[H_{0}(q^{2}, m_{\nu})|^{2} + |H_{+}(q^{2}, m_{\nu})|^{2} + |H_{-}(q^{2}, m_{\nu})|^{2}\right]. \tag{12}
$$

In the above expressions, the helicity amplitudes are:

$$
H_{\pm}(q^{2}, m_{\nu}) = (m_{B} + m_{\nu})A_{1}^{V}(q^{2}) \mp \frac{2m_{B}|\vec{p}_{V}|}{m_{B} + m_{\nu}}V^{V}(q^{2}),
$$

$$
H_{0}(q^{2}, m_{\nu}) = \frac{m_{B} + m_{\nu}}{2m_{\nu}}\left[(m_{B}^{2} - m_{\nu}^{2} - q^{2})A_{1}^{V}(q^{2}) - 4m_{B}^{2}|\vec{p}_{V}|^{2}\right]V^{2}(q^{2)}. \tag{13}
$$

For $B \rightarrow \rho \ell^{-} \bar{\nu}_{\ell}$ decay, a relativistic Breit-Wigner function is used to describe the $\rho$ line shape. The amplitude is

$$
BW(m_{\pi\pi}) = \frac{|\vec{p}_{\pi}|}{m_{\pi\pi}^{2} - m_{\rho}^{2} + im_{\pi\pi}\Gamma(m_{\pi\pi})B(|\vec{p}_{\pi}|)}, \tag{14}
$$

where $m_{\rho}$ is the nominal $\rho$ mass, $|\vec{p}_{\pi}|$ is the pion momentum in the $\rho$ rest frame, $|\vec{p}_{\pi}'|$ is the same but for fixed $m_{\pi\pi} = m_{\rho}$ and

$$
\Gamma(m_{\pi\pi}) = \Gamma_{0}\left(\frac{|\vec{p}_{\pi}|}{|\vec{p}_{\pi}'|}\right)^{3}\frac{m_{\rho}}{m_{\pi\pi}}\left(\frac{B(|\vec{p}_{\pi}'|)}{B(|\vec{p}_{\pi}|)}\right)^{2}, \tag{15}
$$

where $\Gamma_{0}$ is the nominal $\rho$ width, and $B(x)$ is a Blatt-Weisskopf damping factor given by

$$
B(x) = \frac{1}{\sqrt{1 + R^{2}x^{2}}}, \tag{16}
$$

with $R = 3 \ (\text{GeV}/c)^{-1}$.

For the $B^{-} \rightarrow \omega \ell^{-} \bar{\nu}_{\ell}$ decay, a simpler non-relativistic form of the Breit-Wigner function is used for the $\omega$ line shape:

$$
|BW(m)|^{2} = \frac{1}{2\pi} \frac{\Gamma}{(m - m_{\omega})^{2} + (\Gamma/2)^{2}}, \tag{17}
$$

where $m_{\omega}$ and $\Gamma$ are the nominal mass and width of the $\omega$ meson.

III. DATA SAMPLE AND SIMULATION

We use Belle data collected at the energy corresponding to the maximum of the $\Upsilon(4S)$ resonance (10.58 GeV in centre-of-mass frame), equivalent to an integrated luminosity of 711 fb$^{-1}$. Using $B(\Upsilon(4S) \rightarrow B^{0}\bar{B}^{0}) = 0.486 \pm 0.006$ and $B(\Upsilon(4S) \rightarrow B^{+}B^{-}) = 0.514 \pm 0.006$ [5], we can estimate the numbers of produced neutral and charged $B$-meson pairs, $N_{B^{0}\bar{B}^{0}} = (373 \pm 7) \times 10^{6}$ and $N_{B^{+}B^{-}} = (398 \pm 7) \times 10^{6}$. We also utilise a sample of 79 fb$^{-1}$ collected below the $B\bar{B}$ threshold to study the contribution of the $e^{+}e^{-} \rightarrow q\bar{q}$ process, so-called continuum, where $q$ is a $u$, $d$, $s$, or $c$ quark.
Monte Carlo (MC) samples of $e^+e^- \to \Upsilon(4S) \to B\bar{B}$ and continuum, equivalent to five times the integrated luminosity, are used to study the major backgrounds. The simulation accounts for changes in background conditions and beam collision parameters. Final state radiation (FSR) from charged particles is modeled using the PHOTOS package [22].

Dedicated MC samples are generated for charmless semileptonic decays, which are not present in the samples mentioned above. The total number of generated events for the signal MC is based on the number of $B\bar{B}$ pairs in data, scaled by a factor of 20 and assuming branching fractions of $B(\bar{B}_0 \to X + \pi^\pm \ell^- \bar{\nu}_\ell) = 1.709 \times 10^{-3}$ and $B(B^- \to X_0^0 \ell^- \bar{\nu}_\ell) = 1.835 \times 10^{-3}$.

Signal samples with $\bar{B} \to \pi^\pm \nu_\ell$, $\bar{B} \to \rho^\pm \nu_\ell$ and $B^- \to \omega^\pm \nu_\ell$ decays are modeled using Light Cone Sum Rule (LCSR) form factor predictions [23, 24]. Other decays to exclusive meson states are modeled using the updated quark model by Isgur-Scora-Grinstein-Wise (ISGW2) [25]. The inclusive component of charmless semileptonic decays is modeled to leading order $\alpha_s$ based on a prediction in the Heavy-Quark Expansion (HQE) framework [26]. The fragmentation process of the resulting parton to the final hadron state is modeled using the PYTHIA package [27].

In the analysis, for the $\bar{B} \to \pi^\pm \nu_\ell$ decay modes, the signal MC events are reweighted to reproduce the best parametrization by Bourrely, Caprini and Lellouch (BCL), Eq. 39 in [28], because the extrapolation of the LCSR prediction from [23] is inadequate for the high $q^2$ region.

### IV. EVENT SELECTION

Semileptonic $B$-meson decay candidates in events passing the full reconstruction procedure are selected. This procedure provides a NeuroBayes output variable $\alpha_{\text{tag}}$ that varies from zero to unity and tends to have larger values in cases where the fully reconstructed tagging candidate is a correctly reconstructed $B$ meson. To suppress continuum events, the $\alpha_{\text{tag}}$ variable, combined with 18 modified Fox-Wolfram moment variables [29] in a neural net, is used to form a variable, $\alpha_{\text{tag}}^\text{cs}$. Only high quality hadronic tag candidates with $\ln \alpha_{\text{tag}}^\text{cs} > -6$ are selected. This corresponds to a rejection of candidates with a probability to be a $B$ meson of less than 0.25%. An additional selection criterion is applied based on the beam-constrained mass $M_{bc} = \sqrt{E_{\text{beam}}^2/c^4 - (\sum p_i/c)^2}$, where $E_{\text{beam}}$ is the beam energy in the centre of mass frame and the $\vec{p}_i$ are the 3-momenta of the detected particles that form the $B$-meson candidate in the same frame. The candidate must satisfy the condition $M_{bc} > 5.27$ GeV/c².

It is possible to have several $B$ candidates after full reconstruction. In this case, depending on the recoiling system of interest, we select the candidate with the highest probability assigned by the full reconstruction algorithm.

All charged particles are required to originate from the region near the interaction point (IP) of the electron and positron beams. With respect to a cylindrical system with origin at the IP, axis of symmetry $z$ aligned opposite the positron beam direction and radial coordinate $r$, this region is defined as $|z_{\text{PCA}}| < 2$ cm and $r_{\text{PCA}} < 0.4$ cm, where $z_{\text{PCA}}$ and $r_{\text{PCA}}$ are the coordinates of the point of closest approach (PCA) of the reconstructed charged particle to the $z$ axis. All other charged particles are ignored. After applying the above, we treat all selected charged particles as originating from $B$-meson decays.

Electron candidates are identified using the ratio of the energy detected in the ECL to the track momentum, the ECL shower shape, position matching between the track and ECL
cluster, the energy loss in the CDC, and the response of the ACC [30]. Muons are identified based on their penetration range and transverse scattering in the KLM detector [31]. In the momentum region relevant to this analysis, charged leptons are identified with an efficiency of about 90% while the probability to misidentify a pion as an electron (muon) is 0.25% (1.4%). Charged pion candidates are selected with an efficiency of 85% and a kaon misidentification probability of 19%, based on the responses of the CDC, ACC and TOF subdetectors.

To reject leptons from $\gamma$-conversions in the detector material and from $J/\psi$ and $\psi'$ decays, $M_{\ell\ell}$, the invariant mass of all oppositely charged lepton ($\ell = e$ or $\mu$) pairs, is checked and particles are vetoed if $M_{\ell\ell} < 0.1$ GeV/$c^2$, $3.00$ GeV/$c^2 < M_{\ell\ell} < 3.12$ GeV/$c^2$ or $3.60$ GeV/$c^2 < M_{\ell\ell} < 3.75$ GeV/$c^2$.

After a tag candidate has been selected, we look for a lepton amongst the rest of the reconstructed particles not already assigned to this tagging $B$ meson. For $B^{\pm}$, only leptons with the correct charge are selected, whereas for $B^0$, because of mixing, both lepton charges—in other words, all flavors regardless of the reconstructed flavor of the neutral $B$-meson tag—are accepted. A chosen electron must have a momentum in the laboratory frame $|\vec{p}_{\text{lab}}| > 300$ MeV/$c$, whilst a muon must satisfy $|\vec{p}_{\text{lab}}| > 600$ MeV/$c$. These thresholds are chosen based on the known performance properties of the Belle particle identification algorithms. If several particles pass these requirements, the particle with the highest probability to be a lepton, as assigned by the reconstruction algorithm, is selected.

In the electron case, we consider all photons in the event that do not belong to the tag side; if a photon is found whose direction lies within a $3^\circ$ cone around the electron direction, we add the photon 4-momentum to that of the electron and exclude the photon from further analysis. In cases where more than one photon is found, only the nearest photon is merged with the electron.

From the tag side, we derive the signal $B$ meson momentum 4-vector in the $\Upsilon(4S)$ rest frame using only the tag direction, by explicitly requiring the invariant mass to be the $B$ meson mass:

$$p_{B_{\text{sig}}} \equiv (E_{B_{\text{sig}}}/c, \vec{p}_{B_{\text{sig}}}) = c \left( \frac{m_{\Upsilon(4S)}}{2} - \frac{m_{B_{\text{tag}}}}{2} \right)^2 - \frac{m_{\Upsilon(4S)}^2}{4} - m_B^2. \quad (18)$$

We select photons that are not assigned to the tag side with energy in the laboratory frame of $E_{\gamma} > 50$ MeV. To form a $\pi^0$ candidate, we take all possible combinations of two photons; those with invariant mass in the range $|M_{\gamma\gamma} - m_{\pi^0}| < 15$ MeV/$c^2$ are selected as $\pi^0$ candidates. The selection is shown in Fig. 4(b).

We require the number of signal-side charged particles, i.e., charged particles that have not been assigned to the tagging $B$ meson candidate, to equal the number of charged particles expected for the particular decay mode under study.

To calculate the residual energy, $E_{ECL}$, in the electromagnetic calorimeter, we use photons that have not been assigned to either the signal or tag sides. The photons are boosted from the laboratory frame to the $\Upsilon(4S)$ rest frame and the energies are summed. For each decay mode, the selection criterion on the residual energy is optimised for maximal signal significance.

Combining the momentum 4-vectors of the selected hadron system and the lepton on the signal side, and denoting the so-constructed pseudoparticle $Y$, we have $p_Y = p_{\text{hadrons}} + p_\ell$. We can then calculate the cosine of the angle between the direction of the signal side $B$
meson and the $Y$ in the $\Upsilon(4S)$ frame:

$$\cos \theta_{BY} = \frac{2E_{B_{\text{sig}}}E_{Y}/c^2 - m_\rho^2c^2 - m_Y^2c^2}{2|\vec{p}_{B_{\text{sig}}}||\vec{p}_Y|},$$

(19)

where $m_Y$ is the invariant mass of the pseudoparticle. For signal decays, the condition $|\cos \theta_{BY}| < 1$ must be fulfilled. Allowing for resolution effects, we select events using the loose selection $|\cos \theta_{BY}| \leq 3$, keeping all correctly reconstructed events and suppressing a majority of the background. This choice provides us with enough background events to fix background shapes in the fit procedure described below.

Having reconstructed the momentum 4-vectors of the candidate signal $B$ meson and pseudoparticle $Y$, we define the missing momentum 4-vector as

$$p_{\text{miss}} \equiv (E_{\text{miss}}/c, \vec{p}_{\text{miss}}) = p_{B_{\text{sig}}} - p_Y.$$  

(20)

For a correctly reconstructed semileptonic decay, $p_{\text{miss}}$ represents the momentum 4-vector of a single missing neutrino, with missing mass squared $M_{\text{miss}}^2 \equiv p_{\text{miss}}^2/c^2$ consistent with zero.

The missing energy is required to satisfy $E_{\text{miss}} > 300$ MeV to avoid backgrounds where the $B$ meson decays hadronically but a pion from this decay is misidentified as a muon.

For $B^- \rightarrow \pi^0\ell^+\bar{\nu}_\ell$ candidates, we select the $\pi^0$ that gives the smallest value of the magnitude of $M_{\text{miss}}^2$, defined in this case as $|p_{B_{\text{sig}}}-p_\ell-p_{\pi^0}|^2$. The angle $\psi_{\gamma\gamma}$ between photons from the $\pi^0$ decay must satisfy $\cos \psi_{\gamma\gamma} > 0.25$, which mainly suppresses background where one photon candidate arises from activity in the backward endcap and the other from the forward endcap, forming a fake $\pi^0$. The residual energy is required to satisfy the condition $E_{\text{ECL}} < 0.6$ GeV.

For $B^0 \rightarrow \pi^+\ell^-\bar{\nu}_\ell$ candidates, we require that both charged particles be close to each other at the PCA: $|z_{\pi^+} - z_{\ell^-}| < 1$ mm. Because the pion and lepton originate from the same vertex, they should have matching $z$-coordinate values at the start of the track, in the vicinity of the IP. We require the residual energy to satisfy $E_{\text{ECL}} < 1$ GeV. In the case of the charged lepton being a muon, we test the hypothesis that the selected pion is actually a muon from a $J/\psi$ decay misidentified as a pion, and reject events where $|M_{\mu\pi} - m_{J/\psi}| < 20$ MeV$/c^2$, assuming the muon hypothesis for both particles.

For $B^- \rightarrow \rho^0\ell^-\bar{\nu}_\ell$ candidates, we require all charged particles to originate from the same vertex, $|z_{\rho} - z_{\ell^-}| < 1$ mm and $|z_{\rho} - z_{\pi^+}| < 1$ mm. The residual energy must satisfy $E_{\text{ECL}} < 0.7$ GeV. We select events where the invariant mass of the two pions is around the nominal $\rho$ meson mass, requiring $|M_{\pi^+\pi^-} - m_{\rho}| < 2\Gamma_{\rho}$ where $m_{\rho} = 775.5$ MeV$/c^2$ and $\Gamma_{\rho} = 149.1$ MeV$/c^2$ are the nominal $\rho$ mass and decay width, respectively.

For $B^0 \rightarrow \rho^0\ell^-\bar{\nu}_\ell$ candidates, we select the $\pi^+\pi^0$ pair with the largest energy $E_{\pi^+\pi^0}$ in the $\Upsilon(4S)$ rest frame. The residual energy must satisfy $E_{\text{ECL}} < 0.7$ GeV. The angle between the photons must satisfy $\cos \psi_{\gamma\gamma} > 0.4$. The two charged particles must originate from the same vertex: $|z_{\pi^+} - z_{\pi^0}| < 1$ mm. We reject events where the invariant mass of the two particles, assuming the muon hypothesis, lies close to the $J/\psi$ mass, i.e., with $|M_{\mu\pi} - m_{J/\psi}| < 20$ MeV$/c^2$. As for $B^- \rightarrow \rho^0\ell^-\bar{\nu}_\ell$, we require $|M_{\pi^+\pi^-} - m_{\rho}| < 2\Gamma_{\rho}$.

For $B^- \rightarrow J/\psi\ell^-\bar{\nu}_\ell$ candidates where $\omega \rightarrow \pi^+\pi^-\pi^0$, we select the $\pi^+\pi^-\pi^0$ combination containing the $\pi^0$ that has the invariant mass closest to the nominal $\omega$ meson mass and require $-40$ MeV$/c^2 < M_{\pi^+\pi^-\pi^0} - m_{\omega} < 30$ MeV$/c^2$, where $m_{\omega} = 782.65$ MeV$/c^2$. The residual energy must satisfy $E_{\text{ECL}} < 0.5$ GeV. The angle between the photons must satisfy $\cos \psi_{\gamma\gamma} > 0.25$. The charged particles must originate from the same vertex: $|z_{\pi^+} - z_{\pi^0}| < 1$ mm and $|z_{\pi^+} - z_{\pi^0}| < 1$ mm.
For $B^- \rightarrow \omega \ell^- \bar{\nu}_\ell$ candidates where $\omega \rightarrow \pi^0 \gamma$, we consider $\pi^0 \gamma$ pairs for which $-40 \text{ MeV}/c^2 < M_{\pi^0 \gamma} - m_\omega < 30 \text{ MeV}/c^2$ and then select the pair that gives the smallest value of $M^2_{\text{miss}} = |p_{\text{Bsig}} - p_\ell - p_{\pi^0 \gamma}|^2$. The residual energy must satisfy $E_{\text{ECL}} < 0.5 \text{ GeV}$. The angle between the photons from the $\pi^0$ decay must satisfy $\cos \theta_{\pi^0} > 0.4$. The angle $\theta_\gamma$ between the photon from the $\omega$ decay in the $\omega$ rest frame and the $\omega$ direction in the laboratory frame must satisfy $| \cos \theta_\gamma | < 0.5$.

V. HADRONIC TAG CALIBRATION

In this analysis, we use charmed semileptonic $B$-meson decays to calibrate the tagging efficiency, due to their large and well known branching fractions. We can predict the number of events $N(B \rightarrow \text{hadrons}, B \rightarrow X_c \ell^- \bar{\nu}_\ell)$, where one $B$ meson is reconstructed by the full reconstruction algorithm in a $B$-meson hadronic decay mode and the other $B$ meson is reconstructed in an exclusive charmed semileptonic mode. We define

$$N(B \rightarrow \text{hadrons}, B \rightarrow X_c \ell^- \bar{\nu}_\ell) =$$

$$N_{\text{B}} \times B(B \rightarrow \text{hadrons}) \times B(\bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell) \times \varepsilon_{\text{rec}}^{\text{rec}}(B \rightarrow \text{hadrons}, \bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell),$$

where $\varepsilon_{\text{rec}}^{\text{rec}}(B \rightarrow \text{hadrons}, \bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell)$ is the reconstruction efficiency for the specific tag and signal modes. To correct for the specific hadronic tag modes, we factorise the efficiency

$$\varepsilon_{\text{rec}}^{\text{rec}}(B \rightarrow \text{hadrons}, \bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell) = \varepsilon_{\text{rec}}^{\text{rec}}(B \rightarrow \text{hadrons}) \times \varepsilon_{\text{rec}}^{\text{rec}}(\bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell) \times C,$$

where $C$ is a correlation factor between the tag and signal sides that accounts for the lower probability to reconstruct the tag in the case where many particles are present on the signal side. We assume that the MC accurately describes the product $\varepsilon_{\text{rec}}^{\text{rec}}(\bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell) \times C$ because the dynamics of exclusive $\bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell$ decays are well known.

The decay rates in the MC used to calibrate the hadronic tag efficiency are reweighted to the recent PDG values using the correction factors given in Table I. We adjust the number of produced $B^0 \bar{B}^0$ and $B^+ B^-$ pairs in the MC, which were produced with the assumption of an equal production rate, using the $\Upsilon(4S)$ branching fractions into $B$ mesons mentioned in Section III.

To evaluate the tag correction factor, we fit the $M^2_{\text{miss}}$ distribution separately for each hadronic tag mode, split by charmed semileptonic mode. For each tag mode, we calculate the average correction factor over all charmed semileptonic modes and use it to reweight events in the MC.

Overall, the tag efficiency correction is about $\varepsilon_{\text{DATA}}^{\text{rec}}(B \rightarrow \text{hadrons})/\varepsilon_{\text{MC}}^{\text{rec}}(B \rightarrow \text{hadrons}) \sim 0.75$ and varies by several percent depending on the chosen semileptonic mode, due to tag- and signal-side interference. The statistical precision of the calibration is 1.3% for $B^\pm$ and 1.8% for $B^0$ decay modes. We estimate the systematic uncertainty due to the PDG branching fraction uncertainties to be 3.0% for $B^\pm$ and 2.5% for $B^0$ decay modes. To select semileptonic decays with $D^{(*)}$ mesons, we use the particle identification capabilities of the Belle detector. We estimate the systematic uncertainty due to particle identification for the $B^+$ tag to be 2.3% and for the $B^0$ tag 3.0%. The total uncertainty of the tag correction, with correlations between modes included, is estimated to be 4.2% for $B^+$ and 4.5% for $B^0$. We do not count the lepton identification correction and its uncertainty as part of the systematic uncertainty because it cancels in the ratio for the studied charmless semileptonic decays.
TABLE I: Branching fractions with uncertainties from PDG [5], used for the hadronic tag calibration, as well as the branching fraction used in the Belle MC.

| Decay process           | $B^{\text{PDG}}$, % | $B^{\text{MC}}$, % | $B$ ratio |
|-------------------------|---------------------|---------------------|-----------|
| $B^{-} \to D^{0} \ell^{-} \bar{\nu}_{\ell}$ | $2.23 \pm 0.11$   | $2.31$             | 0.965     |
| $B^{-} \to D^{*0} \ell^{-} \bar{\nu}_{\ell}$ | $5.68 \pm 0.19$   | $5.79$             | 0.981     |
| $\bar{B}^{0} \to D^{+} \ell^{-} \bar{\nu}_{\ell}$ | $2.17 \pm 0.12$   | $2.13$             | 1.019     |
| $\bar{B}^{0} \to D^{*+} \ell^{-} \bar{\nu}_{\ell}$ | $5.05 \pm 0.12$   | $5.33$             | 0.947     |
| $D^{0} \to K^{-}\pi^{+}$ | $3.87 \pm 0.05$   | $3.82$             | 1.013     |
| $D^{0} \to K^{-}\pi^{+}\pi^{0}$ | $13.9 \pm 0.5$    | $13.43$            | 1.035     |
| $D^{0} \to K^{-}2\pi^{+}\pi^{-}$ | $8.07 \pm 0.20$   | $7.155$            | 1.128     |
| $D^{+} \to K^{-}2\pi^{+}$ | $9.13 \pm 0.19$   | $9.594$            | 0.952     |
| $D^{+} \to K^{-}2\pi^{+}\pi^{0}$ | $5.99 \pm 0.18$   | $6.03$             | 0.993     |
| $D^{+} \to K^{-}3\pi^{+}\pi^{-}$ | $0.56 \pm 0.05$   | $0.6252$           | 0.896     |
| $D^{*0} \to D^{0}\pi^{0}$ | $61.9 \pm 2.9$    | $61.9$             | 1.000     |
| $D^{*0} \to D^{0}\gamma$ | $38.1 \pm 2.9$    | $38.1$             | 1.000     |
| $D^{*+} \to D^{0}\pi^{+}$ | $67.7 \pm 0.5$    | $67.7$             | 1.000     |
| $D^{*+} \to D^{+}\pi^{0}$ | $30.7 \pm 0.5$    | $30.7$             | 1.000     |

VI. SIGNAL EXTRACTION

To obtain the number of signal events passing all selection criteria for any given decay mode, we fit the $M^{2}_{\text{miss}}$ distribution, for which signal events are expected to peak at $M^{2}_{\text{miss}} = 0$. We use a maximum likelihood technique [32] which also takes into account finite MC statistics in the template histograms that form the components of the fit. The effect on the fitting procedure of using MC $M^{2}_{\text{miss}}$ templates with finite statistics is checked using a toy MC procedure. We find that the fit procedure itself does not introduce a bias for the decay modes studied, and parameter uncertainties match expectations.

A. Components of the fit

To describe the data $M^{2}_{\text{miss}}$ distributions, we divide the MC samples into various components, each defining a template, depending on the decay mode studied. To better describe the amount of $\bar{B} \to X_{u} \ell^{-} \bar{\nu}_{\ell}$ cross-feed, we adjust, where relevant, the MC branching fractions to those obtained in this study.

For the $B^{-} \to \pi^{0}\ell^{-}\bar{\nu}_{\ell}$ decay, we define the following components: $B^{-} \to \pi^{0}\ell^{-}\bar{\nu}_{\ell}$ signal, $\bar{B} \to X_{u} \ell^{-} \bar{\nu}_{\ell}$ cross-feed, other $B$-meson decays and $q\bar{q}$ continuum. The continuum component is fixed to the MC prediction and the normalisations of all other components are free parameters of the fit.

For the $\bar{B}^{0} \to \pi^{+}\ell^{-}\bar{\nu}_{\ell}$ decay, we define the following components: $\bar{B}^{0} \to \pi^{+}\ell^{-}\bar{\nu}_{\ell}$ signal, $\bar{B}^{0} \to \rho^{+}\ell^{-}\bar{\nu}_{\ell}$ cross-feed, other $\bar{B} \to X_{u} \ell^{-} \bar{\nu}_{\ell}$ cross-feed, other $B$-meson decays and $q\bar{q}$ contin-
uum. The continuum component is fixed to the MC prediction, the amount of $B^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ cross-feed is fixed to the value obtained in the $B^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ fit and all other components are free parameters of the fit.

For the $B^- \to \rho^0 \ell^- \bar{\nu}_\ell$ decay, we define the following components: $B^- \to \rho^0 \ell^- \bar{\nu}_\ell$ signal, $B^- \to f_0 \ell^- \bar{\nu}_\ell$, $B^- \to f_2 \ell^- \bar{\nu}_\ell$, $B^- \to \omega \ell^- \bar{\nu}_\ell$, other $B^- \to X_u \ell^- \bar{\nu}_\ell$ cross-feed, $B^- \to D^{0*0} \ell^- \bar{\nu}_\ell$ in which the $D^0$ decays to $K^- \pi^+$ or $\pi^+ \pi^-$ final states, other $B$-meson decays and $q\bar{q}$ continuum. The continuum, $B^- \to f_0 \ell^- \bar{\nu}_\ell$ and $B^- \to \omega \ell^- \bar{\nu}_\ell$ components are small and fixed to the MC prediction; the amounts of $B^- \to f_2 \ell^- \bar{\nu}_\ell$, $B^- \to D^{0*0} \ell^- \bar{\nu}_\ell$ in which the $D^0$ decays to $K^- \pi^+$ or $\pi^+ \pi^-$ final states and cross-feeds are fixed to the values obtained from the invariant mass fit that is described later. All other components are free parameters of the fit.

For the $B^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ decay, we define the following components: $B^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ signal, $B^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ cross-feed, other $B^- \to X_u \ell^- \bar{\nu}_\ell$ cross-feed, $B^0 \to D^{0*0} \ell^- \bar{\nu}_\ell$ in which the $D^0$ decays to $\pi^+ \pi^0$, other $B$-meson decays and $q\bar{q}$ continuum. The continuum component is fixed to the MC prediction, the amount of $B^- \to \omega \ell^- \bar{\nu}_\ell$ cross-feed is fixed to the values obtained in the $B^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ fit, and the amount of $B^0 \to D^{0*0} \ell^- \bar{\nu}_\ell$ in which the $D^+$ decays to $\pi^+ \pi^0$ is fixed to the value obtained from the invariant mass fit. The normalisations of all other components are free parameters of the fit.

For the $B^- \to \omega \ell^- \bar{\nu}_\ell$ decay, we define the following components: $B^- \to \omega \ell^- \bar{\nu}_\ell$ signal ($\omega \to \pi^+ \pi^- \pi^0$ or $\omega \to \pi^0 \gamma$), $B^- \to X_u \ell^- \bar{\nu}_\ell$ cross-feed, other $B$-meson decays and $q\bar{q}$ continuum. The continuum component is fixed to the MC prediction and all other components are free parameters of the fit.

B. Fit results

The fitted $M^2_{\text{miss}}$ distributions are shown in Fig. 1 for $B \to \pi \ell^- \bar{\nu}_\ell$ decays, in Fig. 2 for $B \to \rho \ell^- \bar{\nu}_\ell$ decays and in Fig. 3 for $B^- \to \omega \ell^- \bar{\nu}_\ell$ decays.

The parameter values obtained from the fit, as well as the values of the fixed parameters, are presented in Tables II–VI.

Figure 4 shows various kinematic variables as well as the selection criteria for several decay modes. In these figures, the MC components have been scaled according to the fit result. The same distributions for other decay modes also show similar level of data/MC agreement and are not shown here.

Since the signal MC has been generated in proportion to the number of $B\bar{B}$ pairs, the assumption of efficiency cancellation lets us evaluate the branching fraction of specific semileptonic decay modes over the entire $B$ meson decay phase space as follows:

$$B^\text{DATA}(B \to X_u \ell \nu) = B^\text{MC}(B \to X_u \ell \nu) \frac{N^\text{fit}}{N^\text{MC}},$$

where $N^\text{fit}$ is the fitted signal yield, and $N^\text{MC}$ is the number of signal events in MC with efficiency corrections applied. The fitted signal yields and corresponding MC predictions, along with the resulting branching fractions, are summarised in Table VII. Because of the marginal contribution of the $B^- \to \omega(\pi^0 \gamma) \ell^- \bar{\nu}_\ell$ decay, as seen in this table, we do not consider this mode further. The systematic uncertainties are described below.
FIG. 1: (Color online) Fit to the $M_{\text{miss}}^2$ distributions in data for $B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell$ decays (top) and $B^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$ decays (bottom). The fit components are described in the text.

FIG. 2: (Color online) Fit to the $M_{\text{miss}}^2$ distribution in data for $B^- \rightarrow \rho^0 \ell^- \bar{\nu}_\ell$ decays (top) and $B^0 \rightarrow \rho^+ \ell^- \bar{\nu}_\ell$ (bottom). The fit components are described in the text.
FIG. 3: (Color online) Fit to the $M^2_{\text{miss}}$ distribution in data for $B^- \rightarrow \omega \ell^- \bar{\nu}_\ell$ decays where $\omega \rightarrow \pi^+\pi^-\pi^0$ (top) and $\omega \rightarrow \pi^0\gamma$ (bottom). The fit components are described in the text.

| TABLE II: Fitted yields for $B^- \rightarrow \pi^0\ell^-\bar{\nu}_\ell$ decays. |
|--------------------------------------------------|
| Component | Yield       |
| $B^- \rightarrow \pi^0\ell^-\bar{\nu}_\ell$ | $232.2 \pm 22.6$ |
| $\bar{B} \rightarrow X_u\ell^-\bar{\nu}_\ell$ | $100.0 \pm 86.7$ |
| $B\bar{B}$ | $1993.4 \pm 90.7$ |
| $q\bar{q}$ | $18.5$ (fixed) |
| $\chi^2$/ndf | $56.3/50$ |

C. Signal extraction in bins of $q^2$

We also perform signal extractions in bins of $q^2$. To obtain the number of signal events, we perform a two-dimensional binned maximum likelihood fit in the $q^2$-$M^2_{\text{miss}}$ plane. The shapes of the fit components are taken from MC and they are organised as described above. The signal component, as well as the $B\bar{B}$ component, is allowed to float in each $q^2$ bin independently. The rest of the components are varied or fixed in the same manner as in the $q^2$-independent $M^2_{\text{miss}}$ fit and the parameters of the fit are the yields of each component in the entire $q^2$-$M^2_{\text{miss}}$ plane. The $M^2_{\text{miss}}$ distributions are shown in Fig. 5 for $B^-\rightarrow \pi^0\ell^{-}\bar{\nu}_\ell$ decays, Fig. 6 for $\bar{B}^0\rightarrow \pi^+\ell^{-}\bar{\nu}_\ell$ decays, Fig. 7 for $B^-\rightarrow \rho^0\ell^{-}\bar{\nu}_\ell$ decays, Fig. 8 for $\bar{B}^0\rightarrow \rho^+\ell^{-}\bar{\nu}_\ell$ decays and Fig. 9 for $B^-\rightarrow \omega(3\pi)\ell^{-}\bar{\nu}_\ell$ decays. We correct for the effects of finite detector resolution and bremsstrahlung on the $q^2$ distributions using a simple unfolding procedure described in our previous untagged measurement [13], involving the product of the inverse response matrix that is built using the true and reconstructed $q^2$ variables, with the vector of yields as a function of $q^2$. The extracted yields and partial branching fractions, as well as the full statistical correlation matrices, are given in the Appendix. A comparison of the yields and resulting branching fractions obtained from the fits in bins of $q^2$ with those obtained from fits to the entire $q^2$ range is shown in Table VIII. As can be seen, they are in excellent agreement.

D. Discussion

In the case of exact isospin symmetry, there are known relations between hadronic states with different isospin projections. For $\bar{B}\rightarrow \pi\ell^{-}\bar{\nu}_\ell$ decays,

$$2 \times \frac{\mathcal{B}(B^-\rightarrow \pi^0\ell^{-}\bar{\nu}_\ell)}{\mathcal{B}(\bar{B}^0\rightarrow \pi^+\ell^{-}\bar{\nu}_\ell)} = 1$$

(24)

and similarly, for $B\rightarrow \rho\ell^{-}\bar{\nu}_\ell$ decays,

$$2 \times \frac{\mathcal{B}(B^-\rightarrow \rho^0\ell^{-}\bar{\nu}_\ell)}{\mathcal{B}(B^0\rightarrow \rho^+\ell^{-}\bar{\nu}_\ell)} = 1.$$  

(25)

FIG. 5: (Color online) Projection onto the $M_{\text{miss}}^2$ axis of the fitted distribution to data for $B^+ \rightarrow \pi^0 \ell^- \bar{\nu}_\ell$ decay, for 7 bins in $q^2$.

FIG. 6: (Color online) Projection onto the $M_{\text{miss}}^2$ axis of the fitted distribution to data for $B^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$ decay, for 13 bins in $q^2$. 
FIG. 7: (Color online) Projection onto the $M_{\text{miss}}^2$ axis of the fitted distribution to data for $B^- \to \rho^0 \ell^{-} \bar{\nu}_\ell$ decay, for 11 bins in $q^2$.

FIG. 8: (Color online) Projection onto the $M_{\text{miss}}^2$ axis of the fitted distribution to data for $B^0 \to \rho^+ \ell^{-} \bar{\nu}_\ell$ decay, for 6 bins in $q^2$.

Using the lifetime ratio of neutral to charged $B$ mesons from the PDG [5], $\tau_{B^+}/\tau_{B^0} = 1.079 \pm 0.007$, we can test the isospin relations using the obtained branching fractions and taking into account correlations between measurements:

$$2 \times \frac{\mathcal{B}(B^- \to \pi^0 \ell^{-} \bar{\nu}_\ell)}{\mathcal{B}(B^0 \to \pi^+ \ell^{-} \bar{\nu}_\ell)} \frac{\tau_{B^0}}{\tau_{B^+}} = 1.00 \pm 0.13_{\text{tot}}$$ (26)

and

$$2 \times \frac{\mathcal{B}(B^- \to \rho^0 \ell^{-} \bar{\nu}_\ell)}{\mathcal{B}(B^0 \to \rho^+ \ell^{-} \bar{\nu}_\ell)} \frac{\tau_{B^0}}{\tau_{B^+}} = 1.06 \times (1 \pm 0.13_{\text{tot}}),$$ (27)

FIG. 9: (Color online) Projection onto the $M_{\text{miss}}^2$ axis of the fitted distribution to data for $B^- \to \omega \ell^{-} \bar{\nu}_\ell$ decay, for 3 bins in $q^2$. 

20
which are in a good agreement with the predictions. Using isospin relations, we can present results for the combined branching fractions, taking into account correlations in the systematic uncertainties:

\[
B(\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell) = (1.49 \pm 0.08_{\text{stat}} \pm 0.07_{\text{syst}}) \times 10^{-4}
= (1.49 \pm 0.10_{\text{tot}}) \times 10^{-4}
\]

(28)

and

\[
B(\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell) = (3.34 \pm 0.16_{\text{stat}} \pm 0.17_{\text{syst}}) \times 10^{-4}
= (3.34 \pm 0.23_{\text{tot}}) \times 10^{-4},
\]

(29)

where the total error is obtained by adding the statistical and systematic uncertainties in quadrature. For \( \bar{B} \to \pi^- \bar{\nu}_\ell \) decay, this measurement agrees with recent untagged results from Belle [13] and \( \text{BABAR} \) [12] at a similar level of precision. For \( \bar{B} \to \rho^- \bar{\nu}_\ell \) decay, the branching fraction is 43% (2.7\( \sigma \)) higher than the current PDG value \( B^{\text{PDG}}(\bar{B} \to \rho^- \bar{\nu}_\ell) = (2.34 \pm 0.15 \pm 0.24) \times 10^{-4} \) and the precision is almost twice that of the PDG value.

The branching fraction of \( B^- \to \omega \ell^- \bar{\nu}_\ell \) decay is in good agreement with the PDG value \( B^{\text{PDG}}(B^- \to \omega \ell^- \bar{\nu}_\ell) = (1.15 \pm 0.17) \times 10^{-4} \) and has the same precision.

We note that the obtained branching fractions are fully inclusive of soft photon emission. As an example, the dependence of the reconstruction efficiency of the \( \bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell \) decay on the energy carried away by photons is shown in Fig. 10. It is seen that the detection efficiency is constant for total emitted energy below 300 MeV, where the internal bremsstrahlung process should dominate; MC describes this process using the PHOTOS package. For higher emitted energies, the efficiency drops and should naturally suppress possible direct (or structure-dependent) emission, which is not included in MC.

**VII. SYSTEMATIC UNCERTAINTIES**

The systematic uncertainties are organized into two categories: those related to detector simulation, such as the charged track reconstruction efficiency, particle identification and neutral cluster reconstruction; and effects of the form factor model used in the MC.
The difference between the track reconstruction efficiency for data and MC is estimated using partially reconstructed $D^*$ mesons and found to be 0.35% per charged particle track. This difference is assigned as the track reconstruction systematic error.

We estimate the $\pi^0$ reconstruction efficiency uncertainty to be 2%, from a dedicated study of $\eta$ decays in the modes $\eta \to \pi^+\pi^-\pi^0$ and $\eta \to \gamma\gamma$.

By evaluating the full reconstruction tag efficiency using charmed semileptonic decays of $B$ mesons, we effectively measure the ratio of the branching fractions between charmed and charmless semileptonic decays. In this case, the systematic uncertainty due to the lepton identification mostly cancels. However, the momentum spectra of charmed and charmless semileptonic decays are not the same and this leads to a small difference in the lepton identification efficiency, which we assign as a systematic uncertainty. We conservatively estimate this uncertainty to be the difference between the efficiencies for charmed and charmless semileptonic decay modes and the value is 1%.

The $K/\pi$ separation uncertainty appears in the analysis when we apply a kaon track veto. To obtain the effect of the kaon veto for each decay, the pion angular and momentum distributions are convoluted with the efficiency obtained from a dedicated study of particle identification efficiency using $D^*$ decays. We estimate the uncertainty from the kaon veto to be $\sim 1\%$ per pion track.

We estimate the uncertainty from a possible shape variation in the $M^2_{\text{miss}}$ template histogram for the $B\bar{B}$ component, due to inaccuracies in the charmed semileptonic decay branching fractions used in the MC, by varying these fractions according to the PDG values [5]. The variation in the extracted yields is $\leq 0.1\%$. Due to the smallness of this variation, this uncertainty is not listed in the summary systematic table.

We also establish that our branching fraction results are not sensitive to the particular values chosen for variables used in our selection criteria by varying these within reasonable limits and comparing the results obtained. We find that the variations in the extracted branching fractions stay within statistical fluctuations.

We assign a systematic uncertainty for the modeling of charmless semileptonic cross-feed for the $\bar{B}^0 \to \pi^+\ell^-\bar{\nu}_\ell$ decay and $\bar{B} \to \rho \ell^-\bar{\nu}_\ell$ decays where it was fixed in the fit procedure.

### A. Background to the $\bar{B} \to \rho \ell^-\bar{\nu}_\ell$ decay

In the MC simulation, the inclusive component of charmless semileptonic $B$ meson decays is generated using a HQE model, producing partons that are subsequently hadronized into various hadronic final states using the PYTHIA6.2 package [27]. The most difficult background for $\bar{B} \to \rho \ell^-\bar{\nu}_\ell$ is $\bar{B} \to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ with a non-resonant pion pair, because it is completely indistinguishable from signal when looking at the $M^2_{\text{miss}}$ distribution alone.

To estimate the possible $\bar{B} \to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ non-resonant component, we perform a binned two-dimensional maximum likelihood fit to the $M_{\pi\pi}M^2_{\text{miss}}$ distribution both for $B^- \to \rho^0\ell^-\bar{\nu}_\ell$ and $\bar{B}^0 \to \rho^+\ell^-\bar{\nu}_\ell$ decays, where the bin size in $M^2_{\text{miss}}$ is the same as shown in Fig. 2 and the bins in invariant mass are shown as vertical lines in Fig. 11. Additionally, this fit allows us to fix the yield of the $B^- \to f_2\ell^-\bar{\nu}_\ell$ decay where $f_2 \to \pi^+\pi^-$, and $B^- \to D^{(*)0}\ell^-\bar{\nu}_\ell$ where $D^0 \to K^+\pi^-$ and the kaon was misidentified as a pion, as well as $D^0 \to \pi^+\pi^-$. The $M_{\pi\pi}$ projections of the fitted distributions in the region $|M^2_{\text{miss}}| < 0.25$ GeV/$c^2$, with the $\bar{B} \to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ component fixed to zero, are shown in Fig. 11. For illustration purposes, the yield of $\bar{B} \to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ predicted by MC is shown at the top of the stack. Relevant numbers extracted from the fit are shown in Table IX. It can be seen that the numbers of
FIG. 11: (Color online) Projection of the fitted distribution to data for the $B^-\to\rho^-\ell^-\bar{\nu}_\ell$ decay onto the $M_{\pi\pi}$ axis. Top plot – $B^-\to\rho^0\ell^-\bar{\nu}_\ell$, bottom plot – $B^0\to\rho^+\ell^-\bar{\nu}_\ell$. The inclusive component $B\to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ predicted by MC is shown on the top of the stack. Vertical lines show the bins in invariant mass used during the fit procedure. The hatched region shows the actual selection criterion on the invariant mass.

$B^-\to\rho^0\ell^-\bar{\nu}_\ell$ and $B^0\to\rho^+\ell^-\bar{\nu}_\ell$ decays are in excellent agreement with those obtained from the $M_{\text{miss}}^2$ distribution fit. The results show that for the $B^-\to\rho^0\ell^-\bar{\nu}_\ell$ decay, the inclusive component decaying into two pions is overestimated in the current MC scheme; at our present sensitivity, the yield is consistent with zero. The extracted number of $B^-\to f_2\ell^-\bar{\nu}_\ell$ decays is more than 5σ away from zero and almost 3 times larger than the ISWG2 model prediction, but we cannot claim that the peak in data around 1.3 GeV/$c^2$ is completely saturated by $B^-\to f_2\ell^-\bar{\nu}_\ell$ decays, and to do this an additional dedicated study is needed. From the above, we estimate the uncertainty from the $B\to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ non-resonant cross-feed to be 1%. For the $B^0\to\rho^+\ell^-\bar{\nu}_\ell$ decay, the fit cannot completely rule out a two-pion inclusive component, but it shows that it is overestimated in MC by at least a factor of two. As a result of the fit, we estimate the uncertainty from the $B\to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ cross-feed to be 5%. In light of the above, in this analysis we excluded the inclusive component that decays to two pions from the generated MC event samples.

The other backgrounds to the $B^-\to\rho^0\ell^-\bar{\nu}_\ell$ decay, $B^-\to\omega\ell^-\bar{\nu}_\ell$ where $\omega\to\pi^+\pi^-$ and $B^-\to f_0\ell^-\bar{\nu}_\ell$ where $f_0\to\pi^+\pi^-$, are expected to be small. Thus, we assign a conservative 100% uncertainty for the $B^-\to\omega\ell^-\bar{\nu}_\ell$ and $B^-\to f_0\ell^-\bar{\nu}_\ell$ components, predicted by the MC simulation. We estimate the total uncertainty from $X_u$ cross-feed to the $B^-\to\rho^0\ell^-\bar{\nu}_\ell$ decay
branching fraction measurement to be 2.4%.

B. Cross-feed from $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ to $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ decays

There is a large cross-feed from $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ to $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ decays because those decays have an identical track topology, with one lepton and one charged pion on the signal side.

For the $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ decay mode, the uncertainty in the $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ cross-feed of 0.9% is estimated from the difference in the yields obtained from the $M_{\pi\pi}^2$ fit where the $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ component was first fixed using the PDG branching fraction value and then to the value obtained in this analysis.

In order to estimate how well the MC describes the shape of this background, we study the effect of vetoing events in the $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ $M_{\text{miss}}^2$ distribution that also pass the selection criteria for $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ events. To suppress as many cross-feed events as possible, we use looser selection criteria to identify $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ decays and compare this to the default selection. About 43% of MC generated $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ decays are removed from the $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ sample in this case. The ratio $N_{\text{DATA}}/N_{\text{MC}}$ changes by $\sim 2\%$ with an expected uncertainty of about 1.4% due to signal counting. We also observe that the veto changes the background shapes under the signal peak considerably, without introducing a large effect on the data/MC ratio. We can therefore say that the MC reproduces the $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ shapes sufficiently well to justify not assigning an additional systematic uncertainty due to this shape variation.

C. Continuum description

A check of the continuum description uncertainty is made using 79 fb$^{-1}$ of off-peak data, collected at a collision energy 60 MeV below the $\Upsilon(4S)$ peak. It is difficult to compare data and MC directly within the selection criteria used in the analysis because of the low off-peak sample size. We loosen the selection criteria on the $Q_\text{tag}^2$ and $M_{\text{bc}}$ variables and compare yields and distributions between $q \bar{q}$ continuum MC and off-peak data. The total number of selected events for each studied decay mode is given in Table X. A comparison of several distributions for the $B^- \to \rho^0 \ell^- \bar{\nu}_\ell$ decay is shown in Fig. 12. Decay distributions for other

decay modes convey a similar picture. As can be seen, the data/MC agreement in most cases is at the level of 10%. Also, the $M_{bc}$ and $M_{miss}^2$ distributions are found to be in good agreement.

It is difficult to claim that within the tighter, default selection criteria used in this analysis, the MC describes continuum events with the same level of agreement. Because of this, the uncertainty due to the continuum description is checked by scaling the continuum template histogram by a factor of 50% and examining the effect on the fits. Based on this, the systematic uncertainty due to the continuum description in MC is found to be less than 1% for all decay modes.
D. Model uncertainty

We estimate the uncertainty related to the form factor shape of $\bar{B} \to \pi \ell^\pm \bar{\nu}_\ell$ as the difference in efficiency when comparing the BCL [28] and KMOW [33] form factor parametrizations. For $\bar{B} \to \rho \ell^\pm \bar{\nu}_\ell$ and $B^- \to \omega \ell^\pm \bar{\nu}_\ell$ decays, we estimate the uncertainty as the difference in the total efficiencies obtained using the LCSR calculation [24] and the ISGW2 model result [25]. The $B^- \to \omega \ell^\pm \bar{\nu}_\ell$ decay has a slightly larger uncertainty than the other decays due to the steeper efficiency dependence on $q^2$.

E. Summary of systematic uncertainties

The summary of the systematic uncertainties is given in Table XI. The total uncertainty is obtained by summing the individual uncertainties in quadrature. For branching fractions evaluated in bins of $q^2$, we assume for each source of systematic uncertainty (with model uncertainty excluded) that the size of the uncertainty is the same for all $q^2$ bins. As a consequence, the total systematic uncertainty is also assumed to be fully correlated between different $q^2$ bins, i.e., it does not affect the shape of the measured $q^2$ spectrum. As there is one dominating source of systematic error—the tag calibration—this assumption should be valid to a good approximation.

To average between different isospin modes, we assume partial correlation in the tag efficiency calibration uncertainty (100% correlation in particle ID and 30% correlation in branching fractions uncertainties used for tag calibration), and 100% correlation in track reconstruction, lepton ID, and kaon veto. The other components of the systematic uncertainty listed in Table XI are assumed to be uncorrelated. Under this assumption, the systematic correlation between the $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ and $B^- \to \pi^0 \ell^- \bar{\nu}_\ell$ modes is 49% and between the $\bar{B}^0 \to \rho^+ \ell^- \bar{\nu}_\ell$ and $B^- \to \rho^0 \ell^- \bar{\nu}_\ell$ modes 35%.

VIII. EXTRACTION OF $|V_{ub}|$

To extract a value for $|V_{ub}|$, we use the expression

$$|V_{ub}| = \sqrt{\frac{C_v \Delta \mathcal{B}}{\tau_B \Delta \zeta}}, \quad (30)$$

where $C_v = 2$ for $B^+$ decay modes and $C_v = 1$ for $B^0$ decay modes, $\tau_B$ is the lifetime of the corresponding $B$ meson, $\Delta \mathcal{B}$ is the measured partial branching fraction within a given region of $q^2$ and $\Delta \zeta = \int d\Gamma/|V_{ub}|^2$ is the normalised partial decay width calculated within that $q^2$ region for each model. Values of $|V_{ub}|$ extracted from charmless semileptonic partial branching fractions within the $q^2$ region valid for each model are given in Table XII. For low $q^2$, the form factor predictions are made using LCSR calculations while, for high $q^2$, the predictions are calculated using Lattice QCD (LQCD). Some calculations give form factor predictions corresponding to the entire $q^2$ region. It is evident that the main contribution to the $|V_{ub}|$ uncertainty comes from theory. The experimental uncertainty is typically 2-3 times less than the corresponding theoretical one. The lifetime values $\tau_{B^0} = 1.519 \pm 0.007$ ps and $\tau_{B^+} = 1.641 \pm 0.008$ ps are taken from the PDG [5].
TABLE XI: Systematic uncertainties for the branching fraction results in percent.

| Source of uncertainty         | Assigned systematic uncertainty for $\bar{B} \to X_u \ell^- \bar{\nu}_\ell$ decays |
|------------------------------|--------------------------------------------------------------------------------------|
| $X_u$                        | $\pi^+$  | $\pi^0$ | $\rho^+$ | $\rho^0$ | $\omega(3\pi)$ |
| **Detector Simulation:**      |          |          |          |          |                |
| Track reconstruction         | 0.35     | -        | 0.35     | 0.7      | 0.7            |
| $\pi^0$ reconstruction       | -        | 2.0      | 2.0      | -        |                |
| Lepton identification        | 1.0      | 1.0      | 1.0      | 1.0      | 1.0            |
| Kaon veto                    | 0.9      | -        | 1.0      | 2.0      | 2.0            |
| Continuum description        | 1.0      | 0.5      | 0.5      | 0.7      | 0.0            |
| $X_u$ cross-feed             | 0.9      | -        | 5.0      | 2.4      | -              |
| Tag calibration              | 4.5      | 4.2      | 4.5      | 4.2      | 4.2            |
| Combined                     | 4.9      | 4.8      | 7.2      | 5.4      | 5.2            |
| **Form Factor Shapes:**      | 1.1      | 1.9      | 1.7      | 1.3      | 3.8            |
| Total systematic error       | 5.0      | 5.1      | 7.4      | 5.6      | 6.4            |

We also perform a $|V_{ub}|$ determination with a model-independent description of $\bar{B} \to \pi \ell^- \bar{\nu}_\ell$ decays assuming isospin symmetry and the BCL form factor parametrization [28], the most recent LQCD calculation by the FNAL/MILC collaboration [36], and the vector form factor value for $f_+(q^2)$ at $q^2 = 0$ calculated in the LCSR framework from [39]. We define a goodness of fit as follows:

$$\chi^2 = \chi^2_{\bar{B} \to \pi \ell^- \bar{\nu}_\ell} + \chi^2_{\text{LCSR}} + \chi^2_{\text{LQCD}}. \quad (31)$$

Here, $\chi^2$ for the $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ and $B^- \to \pi^0 \ell^- \bar{\nu}_\ell$ decay modes is given by:

$$\chi^2_{\bar{B} \to \pi \ell^- \bar{\nu}_\ell} = \sum_{i,j} \delta B_i (C^\text{EXP})^{-1}_{ij} \delta B_j, \quad (32)$$

where $C^\text{EXP} = C^\text{EXP}_{\text{stat}} + C^\text{EXP}_{\text{syst}}$ is the full experimental variance matrix. The statistical variance matrix $C^\text{EXP}_{\text{stat}}$ is presented in the Appendix. The systematic variance matrix $C^\text{EXP}_{\text{syst}}$ is obtained from the uncertainties given in Table XI, excluding the form factor shape uncertainty.

The difference between the measured and predicted partial branching fractions $\delta B_i$ in the $q^2$ range $\Delta q^2_i$ is given by:

$$\delta B_i = B_{i}^\text{exp} - \frac{C_v}{C_v} \int_{\Delta q^2_i} \frac{G_F^2}{24\pi^3} |V_{ub}|^2 \left| f_+(q^2, \vec{b}) \right|^2 |\vec{p}_{\pi}|^3 dq^2, \quad (33)$$

where $C_v = 2$ for $B^- \to \pi^0 \ell^- \bar{\nu}_\ell$ and $C_v = 1$ for $\bar{B}^0 \to \pi^+ \ell^- \bar{\nu}_\ell$, and $f_+(q^2, \vec{b})$ is expressed using the BCL form factor parametrization [28]:

$$f_+(q^2, \vec{b}) = \frac{1}{1 - q^2/m_B^2} \sum_{k=0}^{K} b_k(t_0) z(q^2)^k. \quad (34)$$

27
TABLE XII: Values of the CKM matrix element $|V_{ub}|$ based on rates of exclusive $\bar{B} \to X_u \ell^− \bar{\nu}_\ell$ decays and theoretical predictions of form factors within various $q^2$ ranges. The first uncertainty is statistical, the second is experimental systematic and the third is theoretical. The theoretical uncertainty for the ISGW2 model is not available.

| $X_u$ | Theory | $q^2$ | $N^{\text{fit}}$ | $N^{\text{MC}}$ | $\Delta B$ | $\Delta \zeta$ | $|V_{ub}|$ |

|       |        |       |          |     |          |            |            |            |
|       |        |       |          |     |          |            |            |            |
|       |        |       |          |     |          |            |            |            |
|       |        |       |          |     |          |            |            |            |
|       |        |       |          |     |          |            |            |            |
|       |        |       |          |     |          |            |            |            |

The factor in front of the sum describes the pole due to the presence of the $B^*$ vector resonance with mass $m_{B^*} = 5.325$ GeV/$c^2$; the vector $\vec{b} = (b_0, b_1, b_2, \ldots, b_K)$ for a chosen value of $K$ represents the set of parameters to be determined by the fit. The function $z(q^2) \equiv z(q^2, t_0)$ is given by

$$z(q^2, t_0) = \frac{\sqrt{t_+ - q^2} - \sqrt{t_+ - t_0}}{\sqrt{t_+ - q^2} + \sqrt{t_+ - t_0}} ,$$

where $t_+ = (m_B + m_\pi)^2$ and the optimal choice for $t_0$ is $t_0 = t_{\text{opt}} \equiv (m_B + m_\pi)(\sqrt{m_B} - \sqrt{m_\pi})^2$, which provides a mapping of the physical region $0 < q^2 < (m_B - m_\pi)^2$ onto the symmetric interval $|z| < 0.279$ in the complex $z$-plane. The last parameter $b_K$ in the vector $\vec{b}$ is
TABLE XIII: The elements $B_{0k}$ calculated with $t_0 = t_{opt}$ in units of $10^{-4}$. The other elements can be obtained by the relation $B_{j(j+k)} = B_{0k}$ and the symmetry property $B_{jk} = B_{kj}$.

| $k$ | 0  | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   | 10 | 11  | 12  | 13  | 14  |
|-----|----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| $B_{0k}$ | 197.08 | 41.93 | −109.16 | −58.89 | −2.24 | 12.18 | 11.09 | 5.02 | 2.13 | 0.26 | −0.07 | −0.27 | −0.16 | −0.14 | −0.07 |

constrained by angular momentum conservation at the $B\pi$ threshold:

$$b_K = -\frac{(-1)^K}{K} \sum_{k=0}^{K-1} (-1)^k b_k,$$

leaving only $(b_0, b_1, b_2, \ldots, b_{K-1})$ free. Unitarity and crossing symmetry properties of the form factor constrain the $\vec{b}$ parameters:

$$\sum_{j,k=0}^{K} B_{jk} b_j b_k \leq 1,$$

where the coefficients $B_{0k}$, $0 \leq k \leq 14$ are given in Table XIII.

The contribution to the $\chi^2$ function from the LQCD points is:

$$\chi^2_{\text{LQCD}} = \sum_{i,j} \delta f^\dagger_{+ \text{LQCD}}(q_i^2) (C^\text{LQCD})_{ij}^{-1} \delta f^\dagger_{+ \text{LQCD}}(q_j^2),$$

where $C^\text{LQCD}$ is the full variance matrix provided with the LQCD points $f^\dagger_{+ \text{LQCD}}(q_i^2)$, and

$$\delta f^\dagger_{+ \text{LQCD}}(q_i^2) = f^\dagger_{+ \text{LQCD}}(q_i^2) - f_{+}(q_i^2, \vec{b}).$$

The LQCD points are highly correlated and more than half of the eigenvalues of the LQCD covariance matrix are extremely small (of the order of $10^{-6}$ of the largest eigenvalue) or even negative. To treat this situation, we omit some of the LQCD points as suggested in Ref. [8], leaving only 4 points out of 12. This allows us to build the contribution to the $\chi^2$ from LQCD data.

The LCSR contribution to the total $\chi^2$ is:

$$\chi^2_{\text{LCSR}} = \left( \frac{f^\dagger_{+ \text{LCSR}}(0) - f_{+}(0, \vec{b})}{\delta f^\dagger_{+ \text{LCSR}}(0)} \right)^2,$$

where $f^\dagger_{+ \text{LCSR}}(0) = 0.261^{+0.020}_{-0.023}$ from [39]. In this formalism, the free parameters are $|V_{ub}|$ and the real coefficients $b_k$, $0 \leq k < K$; thus, the total number of free parameters is $N = K + 1$.

A typical fit is shown in Fig. 13, using $\bar{B}^0 \rightarrow \pi^+\ell^-\bar{\nu}_\ell$ and $B^- \rightarrow \pi^0\ell^-\bar{\nu}_\ell$ data, LQCD points and the LCSR form factor prediction at $q^2 = 0$ with $N = 4$.

The fit results obtained using different numbers of parameters in the BCL parametrization, along with all possible combinations of $\bar{B}^0 \rightarrow \pi^+\ell^-\bar{\nu}_\ell$ and $B^- \rightarrow \pi^0\ell^-\bar{\nu}_\ell$ differential branching fractions obtained in this analysis, as well as the theoretical predictions, are shown in Table XIV. It can be seen that the values of $|V_{ub}|$ are in agreement for the different
FIG. 13: Fit to data obtained in this analysis, LQCD points and the LCSR prediction at $q^2 = 0$ using the BCL parametrization, with the number of free parameters $N = 4$. The shaded regions represent the uncertainties of the fit.

For $N > 4$, the form factor parametrization starts to oscillate, reflecting the statistical fluctuations in the data, and does not satisfy the unitarity condition on the parameters $\sum B_{jk}b_jb_k \leq 1$.

To estimate the effect of truncating the series in $z$, we use the most recent untagged Belle [13] and BABAR [12] data, which have better statistical and completely different systematic uncertainties. An example of the combined fit is shown in Fig. 14, with $N = 6$, the largest number of parameters where the unitarity condition is not saturated. For larger numbers of parameters, we artificially force the unitarity condition by adding a component to the $\chi^2$ function that is zero if the unitarity condition is not saturated and steeply rising.
and LCSR prediction with differential branching fractions measured in this analysis, the LQCD form factor points terms in the expansion.

The values of $\chi^2$ extracted using different numbers of terms in the form factor expansion are shown in Table XV. To be sure that the $\chi^2$ minimum is a true minimum, we repeated the fit many times, starting with a random initial vector of parameters $\bar{b}$ that satisfies the unitarity condition. It can be seen from Table XV that the value of $\chi^2$ are shown in Table XV. To be sure that the data set was included in the fit and the “+” sign indicates that the corresponding data set was included in the fit and the “−” sign otherwise.

\[
\chi^2_{\text{unitarity}} = \frac{1}{1-u^{150}} - 1, \quad u = \sum_{j,k=0}^{K} B_{jk} b_j b_k. \tag{41}
\]

The values of $|V_{ub}|$ extracted using different numbers of terms in the form factor expansion are shown in Table XV. To be sure that the $\chi^2$ minimum is a true minimum, we repeated the fit many times, starting with a random initial vector of parameters $\bar{b}$ that satisfies the unitarity condition. It can be seen from Table XV that the value of $|V_{ub}|$ is stable starting from $N = 4$; additional parameters only slightly improve the overall $\chi^2$. From this, we can conclude that the number of terms in the expansion, $K = N - 1 = 3$, is enough to describe the current data with a negligibly small $\sim 0.5\%$ systematic uncertainty due to unaccounted terms in the expansion.

As a result of the model-independent fit of both the $B^0 \to \pi^+ \ell^- \bar{\nu}_\ell$ and $B^- \to \pi^0 \ell^- \bar{\nu}_\ell$ differential branching fractions measured in this analysis, the LQCD form factor points and LCSR prediction with $N = 4$, we quote $|V_{ub}| = (3.52 \pm 0.29) \times 10^{-3}$. It is difficult
TABLE XV: Fit results with different number of free parameters \( N \) and forced unitarity bound on the coefficients of the expansion using untagged Belle [13], \( \text{BABAR} \) [12] and tagged (this study) data and the LCSR and LQCD calculations. Note that in this approach the \(|V_{ub}|\) error cannot be reliably estimated for \( N > 6 \) near to the unitarity bound.

| \( N \) | \( |V_{ub}| \times 10^3 \sum B_{jk} b_j b_k \) | \( \chi^2/\text{ndf} \) |
|------|---------------------|------------------|
| 3    | 3.47 ± 0.21         | 0.0148 46.39/47  |
| 4    | 3.41 ± 0.22         | 0.0232 45.37/46  |
| 5    | 3.39 ± 0.22         | 0.1073 44.76/45  |
| 6    | 3.39 ± 0.22         | 0.2289 44.74/44  |
| 7    | 3.39 ± 0.20         | 0.9501 44.65/43  |
| 8    | 3.39 ± 0.08         | 0.9503 44.65/42  |
| 9    | 3.39 ± 0.09         | 0.9525 44.62/41  |
| 10   | 3.39 ± 0.09         | 0.9525 44.62/40  |
| 11   | 3.39 ± 0.09         | 0.9527 44.59/39  |
| 12   | 3.39 ± 0.11         | 0.9531 44.59/38  |
| 13   | 3.39 ± 0.09         | 0.9538 44.58/37  |
| 14   | 3.39 ± 0.10         | 0.9539 44.58/36  |
| 15   | 3.39 ± 0.09         | 0.9545 44.56/35  |

to unequivocally separate the experimental and theoretical uncertainties so we quote only a total error. Using only the LCSR prediction or LQCD points in the fit as shown in Table XIV, we can conclude that the LCSR prediction and LQCD points have almost equal contributions to the total uncertainty.

In Fig. 15, we show the value of \(|V_{ub}|\) obtained in this analysis, compared to values obtained from other recent measurements and global determinations. The extracted value of \(|V_{ub}|\) has comparable precision to, and agrees with, the values obtained from untagged Belle [13] and \( \text{BABAR} \) [12] data using the same method of determination as in this analysis. The figure shows both the values quoted in the Belle and \( \text{BABAR} \) papers and the values obtained by refitting using the original data and the method used in the present analysis. The combined fit shown uses data from all three analyses. Our value is also in agreement with the results of global fits performed by the CKMfitter [40] and UTfit [41] groups, where they excluded \(|V_{ub}|\) related inputs from the fits. The tension between the value of \(|V_{ub}|\) extracted from \( \bar{B} \to \pi \ell^- \bar{\nu}_\ell \) decays and that measured in inclusive semileptonic decays of \( B \) mesons, represented in the figure by the latest PDG [5] value, remains significant (\( \sim 3\sigma \)).

We note that all theoretical predictions used in \(|V_{ub}|\) extraction procedures described above assume no photon emission in the final state. For future experiments with much larger data samples, it will become crucial for theory to take into account radiative effects to describe high precision experimental data.
IX. CONCLUSION

We measure the total branching fractions for $B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell$, $B^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$, $B^- \rightarrow \rho^0 \ell^- \bar{\nu}_\ell$, $B^0 \rightarrow \rho^+ \ell^- \bar{\nu}_\ell$ and $B^- \rightarrow \omega \ell^- \bar{\nu}_\ell$ decays using fully reconstructed hadronic $B$ decays as a tag. This technique provides exceptionally clean signal samples and thus low systematic uncertainty in the final results. The $B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell$ and $B^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$ branching fractions are in a good agreement with the previous Belle result [13] using an untagged reconstruction technique and with the recent BABAR measurement [12], and also with the isospin symmetry relation. The $B^- \rightarrow \rho^0 \ell^- \bar{\nu}_\ell$ and $B^0 \rightarrow \rho^+ \ell^- \bar{\nu}_\ell$ branching fractions are also in good agreement with the isospin symmetry relation. The $B \rightarrow \rho \ell^- \bar{\nu}_\ell$ branching fraction is 43% (2.7$\sigma$) higher than the PDG value and its precision is almost a factor of two better. This raises the probability that, in the previous analyses, backgrounds to $B \rightarrow \rho \ell^- \bar{\nu}_\ell$ decays may have been considerably overestimated.

For the first time, we have an indication of neutral charmless hadronic states above 1 GeV/$c^2$ in invariant mass in semileptonic decays of $B$ mesons. The broad peak observed in the $\pi^+\pi^-$ invariant mass distribution around 1.3 GeV/$c^2$ is dominated in our fit by the $B^- \rightarrow f_2 \ell^- \bar{\nu}_\ell$ decay where $f_2 \rightarrow \pi^+\pi^-$. The fitted yield is 2-3 times higher than expected.

FIG. 14: The combined fit to the most recent data and theory inputs using the BCL parametrization with the number of free parameters $N = 6$ using untagged Belle [13] and BABAR [12] and tagged (this study) data. Shaded regions represent the uncertainties of the fit.
FIG. 15: The comparison of $|V_{ub}|$ values obtained with the BCL form factor parameterization with the number of terms in expansion $K = 3$, using LCSR and LQCD inputs for tagged (this analysis), untagged Belle [13] and BABAR [12] data as well as a combined fit with those three data sets. The value of $|V_{ub}|$ based on inclusive semileptonic decays of $B$ mesons is taken from the recent PDG [5] review. The CKMfitter [40] and UTfit [41] estimates of $|V_{ub}|$ are from global fits where $|V_{ub}|$ related inputs are excluded. The dashed lines represent $|V_{ub}|$ values quoted in the original papers.

From the ISGW2 model and, assuming the absence of the non-resonant $\bar{B} \to X_u(\pi\pi)\ell^-\bar{\nu}_\ell$ decay, it has high statistical significance. A dedicated study is needed to fully explore the region above 1 GeV/$c^2$.

From the studied decays, we extract values of $|V_{ub}|$ in various $q^2$ regions where the theoretical predictions of the hadronic form factors are valid. The resulting values of $|V_{ub}|$ are in a good agreement with each other. We also measure the $q^2$ dependence of the partial branching fractions, which can be used to test the theoretical predictions for the hadronic form factors.

For the $\bar{B} \to \pi\ell^-\bar{\nu}_\ell$ decay, we extract a value of $|V_{ub}| = (3.52 \pm 0.29) \times 10^{-3}$ using our measured partial branching fractions, a recent LCSR calculation, LQCD points and a model-independent description of the $f_+(q^2)$ hadronic form factor. We also present values of $|V_{ub}|$ obtained from fits where we do not assume that the theoretical inputs from LCSR and LQCD can be included in the same fit. Within the BCL parametrization, we have shown that 3 terms in the $z$ expansion are enough to extract a value of $|V_{ub}|$ with negligibly small systematic uncertainty due to truncating the expansion.

APPENDIX

In this Appendix, we present the fitted event yields, unfolded yields, efficiencies and
corresponding partial branching fractions for the decays investigated in this study, in bins
of $q^2$ in Tables XVI, XVIII, XX, XXII and XXIV. We also give the statistical correlations
between $q^2$ bins in Tables XVII, XIX, XXI, XXIII and XXV.
TABLE XVI: Raw $\bar{B}^0 \to \pi^+\ell^-\bar{\nu}_\ell$ yields obtained from the two-dimensional fit, unfolded yields, efficiencies and partial branching fractions in bins of $q^2$.

| $\Delta q^2$ GeV$^2$/c$^2$ | $N_{\text{fit}}$ | $N_{\text{unfolded}}^{\text{fit}}$ | $\varepsilon$ | $\Delta B$ |
