RANK-DETERMINING SETS OF METRIC GRAPHS

YE LUO

Abstract. A metric graph is a geometric realization of a finite graph by identifying each edge with a real interval. A divisor on a metric graph $\Gamma$ is an element of the free abelian group on $\Gamma$. The rank of a divisor on a metric graph is a concept appearing in the Riemann-Roch theorem for metric graphs (or tropical curves) due to Gathmann and Kerber \cite{gathmann}, and Mikhalkin and Zharkov \cite{mikhalkin}. We define a rank-determining set of a metric graph $\Gamma$ to be a subset $A$ of $\Gamma$ such that the rank of a divisor $D$ on $\Gamma$ is always equal to the rank of $D$ restricted on $A$. We show constructively in this paper that there exist finite rank-determining sets. In addition, we investigate the properties of rank-determining sets in general and formulate a criterion for rank-determining sets. Our analysis is based on an algorithm to derive the $r_0$-reduced divisor from any effective divisor in the same linear system.

1. Introduction

In the past few years, people have been attracted to investigate the analogies and connections among linear systems on algebraic curves, finite graphs, metric graphs and tropical curves \cite{hladky,kral,norine,gathmann,mikhalkin}. In particular, a recent work of Hladký, Král’ and Norine \cite{norine} shows that the rank of a divisor $D$ on a graph equals the rank of $D$ on the corresponding metric graph $\Gamma$. However, their result requires that all the edges of $\Gamma$ have length 1 and $D$ is zero on the interiors of the edges. As an initial step of this paper, we assert that these restrictions are not necessary by proving that for an arbitrary metric graph $\Gamma$ with a vertex set $\Omega$ and an arbitrary divisor $D$ on $\Gamma$, the rank $r(D)$ of $D$ equals the $\Omega$-restricted rank $r_\Omega(D)$ of $D$. This result motivates us into further investigations on the subsets of $\Gamma$ having such a property, to which we give the name rank-determining sets.

1.1. Preliminaries. Throughout this paper, a graph $G$ means a finite connected multigraph with no loop edges, and a metric graph $\Gamma$ means a graph having each edge assigned a positive length. And roughly speaking, a tropical curve is a metric graph where we admit some edges incident with vertices of degree 1 having infinite length \cite{mikhalkin, zharkov}. We will expand our discussions within the framework of metric graphs, while the conclusions also apply for tropical curves.

Denote the vertex set and the edge set of a graph $G$ by $V(G)$ and $E(G)$, respectively. The genus $g$ of $G$ is the first Betti number of $G$ or the maximum number of independent cycles of $G$, which equals $\#E(G) - \#V(G) + 1$.

We can also define vertices and edges on a metric graph $\Gamma$. We call $\Omega$ a vertex set of $\Gamma$ and the elements of $\Omega$ vertices, if $\Omega$ is a nonempty finite subset of $\Gamma$ satisfying the following conditions:

(i) $\Gamma \setminus \Omega$ is a disjoint union of subspaces $e_i^o$ isometric to open intervals.

2000 Mathematics Subject Classification. 05C38, 14H99.

Key words and phrases. Finite graph, Metric graph, Tropical curve, Algebraic curve, Rank-determining set, Special open set.
(ii) Let $e_i$ be the closure of $e^o_i$. For all $i$, $e_i \setminus e^o_i$ contains exactly two distinct points, which are both elements of $\Omega$. We call $e_i$ an edge of $\Gamma$, $e^o_i$ the interior of $e_i$, and $v \in e^o_i$ an internal point of $e_i$. And we say that the two vertices in $e_i \setminus e^o_i$ are two ends (or end-points) of $e_i$ or $e^o_i$, while $e_i$ is an edge connecting these vertices.

Clearly, $\Gamma$ is loopless with respect to $\Omega$. And by our definition of a vertex set, there might be multiple edges between two vertices, which is not allowed in definitions of vertex sets by other authors (see, e.g., [4]). Throughout this paper, whenever we mention a vertex or an edge of a metric graph $\Gamma$, we always assume a vertex set of $\Gamma$ is predetermined, whether or not it is presented explicitly. Given a vertex set of $\Gamma$, the genus of $\Gamma$ can be computed just like in the graph case (note that the genus is independent of how we choose vertex sets).

By identifying each edge with a closed interval, the subintervals are called segments of $\Gamma$. The boundary points of a segment are called the end-points. And to avoid confusion in case of multiple edges, $e$ can be represented by $[w_1, v, w_2]$. We use $\text{dist}(x, y)$ to denote the distance between two points $x$ and $y$ measured on $\Gamma$, and define the distance between two subsets $X$ and $Y$ of $\Gamma$, denoted by $\text{dist}(X, Y)$, to be $\inf\{\text{dist}(x, y), x \in X, y \in Y\}$. If $e'$ is a segment, and $x, y \in e'$, then we use $\text{dist}_{e'}(x, y)$ to denote the distance between $x$ and $y$ measured on $e'$.

For simplicity of notation, if $v$ is a point of a metric graph, sometimes we refer to the singleton $\{v\}$ by just writing $v$.

A divisor $D$ on $G$ is an element of the free abelian group $\text{Div}G$ on the vertex set of $G$. We can uniquely write a divisor $D \in \text{Div}G$ as $D = \sum_{v \in V(G)} D(v)(v)$, where $D(v) \in \mathbb{Z}$ evaluates $D$ at $v$. The degree of $D$ is defined by the formula $\text{deg}(D) = \sum_{v \in V(G)} D(v)$. A divisor $D$ is called effective if $D(v) \geq 0$ for all $v \in V(G)$. We denote the set of all effective divisors on $G$ by $\text{Div}_+G$, and the set of all effective divisors of degree $s$ on $G$ by $\text{Div}_s^+G$. Provided a function $f : V(G) \rightarrow \mathbb{Z}$, the divisor associated to $f$ is given by

$$D_f = \sum_{v \in V(G)} \sum_{e = uv \in E(G)} (f(v) - f(w))(v),$$

and called principal. It is easy to see that the principal divisors have degree 0. For two divisors $D$ and $D'$, we say that $D$ is linearly equivalent to $D'$ or $D \sim D'$ if $D - D'$ is principal.

And we defined the linear system associated to a divisor $D$ to be the set $|D|$ of all effective divisors linearly equivalent to $D$. Since $|D|$ does not have a pure dimension, Baker and Norine [3] introduced the concept of the rank of a divisor $D$, denoted by $r_G(D)$, to describe the dimensional aspect of $|D|$. Explicitly, $r_G(D) = -1$ if $|D| = \emptyset$, and $r_G(D) \geq s \geq 0$ if and only if $|D - E| \neq 0$ for all $E \in \text{Div}_s^+G$. When it is clear that $D$ is defined on $G$, we usually omit the subscript and write $r(D)$ instead of $r_G(D)$.

Analogously, for a metric graph (or a tropical curve) $\Gamma$, elements of the free abelian group $\text{Div}\Gamma$ on $\Gamma$ are called divisors on $\Gamma$. We can define the degree of a divisor and the notion of effective divisors in a similar way. A rational function $f$ on $\Gamma$ is a continuous, piecewise linear real function with integral slopes. The order $\text{ord}_v f$ of $f$ at a point $v \in \Gamma$ is the sum of the outgoing slopes of all the segments emanating from $v$. Any rational function $f$ has an associated a divisor $(f) := \sum_{v \in \Gamma} \text{ord}_v f \cdot (v)$. We say $(f)$ is principal for all rational
functions $f$, and define linear equivalence relations and linear systems as on graphs. Also, we may define the rank $r(T(D))$ of a divisor $D$ on $T$. Explicitly, $r(T(D)) = -1$ if $|D| = \emptyset$, and $r(T(D)) \geq s \geq 0$ if and only if $|D - E| \neq \emptyset$ for all $E \in \text{Div}^+T$. We may omit the subscript and use $r(D)$ to represent the rank of a divisor $D$, when there is no confusion that $D$ is defined on $T$.

1.2. Overview. As an analogue of the classical Riemann-Roch theorem on Riemann surfaces, Baker and Norine formulated and proved the Riemann-Roch theorem for the rank of divisors on finite graphs [3]. We define the canonical divisor on a graph $G$ to be the divisor $K$ given by $K = \sum_{v \in V(G)}(\deg(v) - 2)(v)$.

**Theorem 1.1** (Riemann-Roch theorem for graphs). Let $G$ be a graph of genus $g$ and $K$ the canonical divisor on $G$. Then for all $D \in \text{Div}G$, we have

$$r_G(D) - r_G(K - D) = \deg(D) + 1 - g.$$ 

Not long after, such an analogy was extended to metric graphs and tropical curves by Gathmann and Kerber [7], by Hladký, Král’ and Norine [8], and by Mikhalkin and Zharkov [10]. For a metric graph (or a tropical curve) $T$, we may also define the canonical divisor on $T$ to be the divisor $K$ given by $K = \sum_{v \in T}(\deg(v) - 2)(v)$.

**Theorem 1.2** (Riemann-Roch theorem for metric graphs and tropical curves). Let $T$ be a metric graph (or a tropical curve) of genus $g$ and $K$ the canonical divisor on $T$. Then for all $D \in \text{Div}T$, we have

$$r_T(D) - r_T(K - D) = \deg(D) + 1 - g.$$ 

The following theorem, conjectured by Baker and proved by Hladký, Král’ and Norine [8], states another important property about rank of divisors. For a graph $G$, by assigning all edges length 1, we obtain a metric graph corresponding to $G$.

**Theorem 1.3.** Let $T$ be the metric graph corresponding to a graph $G$. Let $D$ be a divisor on $G$. Let $r_G(D)$ be the rank of $D$ on $G$, and $r_T(D)$ the rank of $D$ on $T$. Then we have $r_G(D) = r_T(D)$.

We introduce a new notion of rank here.

**Definition 1.4.** Let $T$ be a metric graph and $A$ a nonempty subset of $T$.

(i) Define the $A$-restricted rank $r_A(D)$ of a divisor $D \in \text{Div}T$ by $r_A(D) = -1$ if $|D| = \emptyset$, and $r_A(D) \geq s \geq 0$ if and only if $|D - E| \neq \emptyset$ for all $E \in \text{Div}^+_A$.

(ii) $A$ is said to be a rank-determining set of $T$, if it holds for every divisor $D \in \text{Div}T$ that $r(D) = r_A(D)$.

One may also call $r_A(D)$ the rank of $D$ restricted on $A$. Clearly, $T$ itself is a rank-determining set of $T$ and we say it is trivial. It is natural to ask if there exist nontrivial rank-determining sets, or more ambitiously, finite ones? One of the main results of this paper is the following theorem, which gives an affirmative answer.

**Theorem 1.5.** Let $\Omega$ be a vertex set of a metric graph $T$. Then $\Omega$ is a rank-determining set of $T$. 

3
It is easy to see that Theorem 1.5 generalizes Theorem 1.3 to all metric graphs $\Gamma$ and all divisors $D$ on $\Gamma$. And since $\text{Div}_+^e \Omega$ is always a finite set, this theorem also provides an algorithm for computing the rank of a divisor on $\Gamma$.

There exist finite rank-determining sets other than vertex sets. In particular, we will prove the following conjecture of Baker.

**Theorem 1.6.** Let $\Gamma$ be a metric graph of genus $g$. Then there exists a finite rank-determining set of cardinality $g + 1$.

Theorem 1.6 has a counterpart in the algebraic curve case, as stated in the following theorem. (See Remark 3.13 for a sketch of the proof.)

**Theorem 1.7** (R. Varley). For a nonsingular projective algebraic curve $C$, any set of $g + 1$ distinct points is a rank-determining set.

It is clear that the equivalence relation among divisors on $\Gamma$ changes if we use a different metric. However, rank-determining sets will not be affected, even though their definition uses the notion of linear systems on $\Gamma$.

**Theorem 1.8.** Rank-determining sets are preserved under homeomorphisms.

In Section 2 we present an algorithm for computing the $v_0$-reduced divisor linearly equivalent to a given effective divisor on $\Gamma$. In Section 3, we investigate properties of rank-determining sets based on this algorithm, which are generalized into a subtle criterion for rank-determining sets, from which Theorem 1.5, 1.6 and 1.8 easily follow. We also explore several concrete examples as applications of the criterion.

**Acknowledgments:** I would most of all like to thank Matthew Baker for introducing me to this topic, for his encouragement of further study on general properties of rank-determining sets, and for many valuable discussions. Dr. Baker also helped me simplify the proof of Theorem 2.14 and gave detailed comments on the draft. Thanks to Robert Varley for providing his proof of Theorem 1.7 in Remark 3.13. I would also like to thank Serguei Norine for helpful discussions, and Josephine Yu, Robin Thomas, Prasad Tetali and Farbod Shokrieh for their comments.

### 2. From effective divisors to reduced ones

#### 2.1. Reduced divisors.

The notion of reduced divisors was adopted in [3] as an important tool in the proof of the Riemann-Roch theorem for finite graphs. The definition of reduced divisors on finite graphs is based on the notion of $G$-parking functions [11].

Let $G$ be a finite graph. For $A \subseteq V(G)$ and $v \in A$, the out-degree of $v$ from $A$, denoted by $\text{outdeg}_A(v)$, is defined as the number of edges of $G$ with one end at $v$ and the other end in $V(G) \setminus A$. Choose a vertex $v_0$. We say a function $f : V(G) \setminus \{v_0\} \to \mathbb{Z}$ is a $G$-parking function based at $v_0$ if

(i) $f(v) \geq 0$ for all $v \in V(G) \setminus \{v_0\}$, and

(ii) every nonempty subset $A$ of $V(G) \setminus \{v_0\}$ contains a vertex $v$ such that $f(v) < \text{outdeg}_A(v)$.

A divisor $D \in \text{Div}(G)$ is called $v_0$-reduced if the map $v \mapsto D(v)$ restricted on $V(G) \setminus \{v_0\}$ is a $G$-parking function based at $v_0$. An important property of reduced divisors is stated in the following proposition.
Proposition 2.1 (See Proposition 3.1 in [3]). If we fix a base vertex \( v_0 \in V(G) \), then for every \( D \in \text{Div}_G \), there exists a unique \( v_0 \)-reduced divisor \( D' \in \text{Div}_G \) such that \( D' \sim D \).

Proposition 2.1 is quite useful when dealing with equivalence classes of divisors, since we can select a reduced divisor as a concrete representative for each equivalence class of divisors.

The notion of reduced divisors has been extended to metric graphs by several authors. In this paper, we adopt the definition of reduced divisors on metric graphs as in [8], which follows closely the definition of reduced divisors on finite graphs as discussed above. Other authors suggest to define reduced divisors on metric graphs in more abstract ways [2][10], and it can be proved that these definitions are all equivalent.

Let \( \Gamma \) be a metric graph. If \( X \) is a subset of \( \Gamma \) with finitely many connected components, we use \( X^c \) to denote the complement of \( X \) on \( \Gamma \), \( \overline{X} \) the closure of \( X \), \( X^o \) the interior of \( X \), and \( \partial X \) the set of boundary points of \( X \). Note that \( \partial X = \partial X^c \). In addition, if \( X \) is closed, then for \( v \in \partial X \), we define the out-degree of \( v \) from \( X \), denoted by \( \text{outdeg}_X(v) \), to be the number of edges leaving \( X \) at \( v \), or more precisely, the maximum number of internally disjoint segments of \( X \) with an open end at \( v \). For \( D \in \text{Div}_\Gamma \), we call a boundary point \( v \) of \( X \) saturated with respect to \( X \) and \( D \) if \( D(v) \geq \text{outdeg}_X(v) \), and non-saturated otherwise.

Definition 2.2. Fix a base point \( v_0 \in \Gamma \). We say that a divisor \( D \) is \( v_0 \)-reduced if \( D \) is non-negative on \( \Gamma \setminus v_0 \), and every closed connected subset \( X \) of \( \Gamma \setminus v_0 \) contains a non-saturated point \( v \in \partial X \).

As a counterpart of Proposition 2.1, the following theorem asserts the existence and uniqueness of a \( v_0 \)-reduced divisor in any equivalence class of \( \text{Div}_\Gamma \) [8][10].

Theorem 2.3. Let \( D \) be a divisor on a metric graph \( \Gamma \). For any \( v_0 \in \Gamma \), there exists a unique \( v_0 \)-reduced divisor \( D_{v_0} \) that is linearly equivalent to \( D \).

For any finite subset \( S \) of \( \Gamma \), we denote by \( U_{S,v_0} \) the maximal connected subset of \( \Gamma \), such that \( v_0 \in U_{S,v_0} \) and \( \mathcal{S} \setminus U_{S,v_0} = \emptyset \). In particular, if \( v_0 \in S \), then \( U_{S,v_0} = \emptyset \). The set \( U_{S,v_0} \) can be derived by taking the connected component of \( S^c \) which contains \( v_0 \). Note that \( U_{S,v_0} \) is connected and open, while \( U_{S,v_0}^c \) is closed and might have several connected components. We say that \( S \) is \( v_0 \)-minimal if \( U_{S,v_0}^c \) is connected and \( S \) equals the set of boundary points of \( U_{S,v_0} \).

Let \( D \) be a divisor on \( \Gamma \). Let \( \text{supp}D = \{ v \in \Gamma | D(v) \neq 0 \} \) and \( \text{supp}|D| = \bigcup_{D' \sim |D|} \text{supp}|D'| \). We call \( \text{supp}D \) the support of \( D \) and call \( \text{supp}|D| \) the support of \( |D| \).

Assume now that \( D \) is effective. To verify if \( D \) is \( v_0 \)-reduced, we do not need to go through all closed connected subsets of \( \Gamma \setminus v_0 \). The following lemma shows that we only need to consider finitely many of them.

Lemma 2.4. Let \( v_0 \) be a point of \( \Gamma \) and \( D \) an effective divisor on \( \Gamma \). Then \( D \) is \( v_0 \)-reduced if and only if for any subset \( S \) of \( \text{supp}D \setminus v_0 \), \( U_{S,v_0}^c \) contains a non-saturated boundary point with respect to \( D \).

Proof. First assume \( D \) is \( v_0 \)-reduced and consider a subset \( S \) of \( \text{supp}D \setminus v_0 \). Then \( U_{S,v_0}^c \) is a closed subset of \( \Gamma \) which has finitely many components. Apply the defining property of \( v_0 \)-reduced divisors to any of these components, and we obtain non-saturated boundary points on each of them.

Conversely, assume that for any subset \( S \) of \( \text{supp}D \setminus v_0 \), \( U_{S,v_0}^c \) contains a non-saturated point. If \( D \) is not \( v_0 \)-reduced, then there exists a closed connected subset \( X \) of \( \Gamma \setminus v_0 \), such
And since every point of $\partial X$ is saturated with respect to $X$ and $D$. Clearly $\partial X \subseteq \text{supp} D \setminus v_0$. And since $X \subseteq U_{\partial X,v_0}$, the edges leaving $U_{\partial X,v_0}$ must also be edges leaving $X$. Therefore, for every $v \in \partial U_{\partial X,v_0}$, we have

$$D(v) \geq \text{outdeg}_X(v) \geq \text{outdeg}_{U_{\partial X,v_0}}(v).$$

This is equivalent to saying that $U_{\partial X,v_0}$ contains no non-saturated boundary points, which contradicts our assumption. \hfill $\Box$

Lemma 2.4 tells us that to determine if an effective divisor $D$ is $v_0$-reduced, it suffices to consider only the subsets of $\text{supp} D \setminus v_0$. But the number of cases still grows exponentially with respect to $\#\text{supp} D$. For finite graphs, there is an elegant algorithm for verifying if a given function is a $G$-parking function, which is adapted from an algorithm provided by Dhar [6] in the context of sandpile models (see [5]). Here we extend Dhar’s algorithm to metric graphs, as a consequence of which we just need to test the points in $\text{supp} D \setminus v_0$ one by one in order to judge whether an effective divisor $D$ is $v_0$-reduced.

**Algorithm 2.5. (Dhar’s algorithm for metric graphs)**

**Input:** An effective divisor $D \in \text{Div}_+ \Gamma$, and a point $v_0 \in \Gamma$.

**Output:** A subset $S$ of $\text{supp} D \setminus v_0$.

Initially, set $S_0 = \text{supp} D \setminus v_0$, and $k = 0$.

1. If $S_k = \emptyset$ or all the boundary points of $U_{S_k,v_0}$ are saturated with respect to $D$, set $S = S_k$ and stop the procedure.

2. Let $N_k$ be the set of all non-saturated boundary points of $U_{S_k,v_0}$. Set $S_{k+1} = S_k \setminus N_k$. Set $k \leftarrow k + 1$ and go to step (1).

**Lemma 2.6.** Run Dhar’s algorithm for an effective divisor $D$ and a point $v_0$. Then $D$ is $v_0$-reduced if and only if the output $S$ is empty.

**Proof.** If $S$ is nonempty, then all the boundary points of $U_{S_k,v_0}$ are saturated. Thus $D$ is not $v_0$-reduced by Lemma 2.4.

Otherwise, $S = \emptyset$. For a subset $S'$ of $\text{supp} D \setminus v_0$, let $N_k$ be such that $N_k \cap S' \neq \emptyset$ and $N_k \cap S' = \emptyset$ for $k' < k$. Note that $S' \subseteq S_k$. If $v \in N_k \cap S'$, then $v$ must be a non-saturated boundary point of $U_{S_k,v_0}$, since

$$D(v) < \text{outdeg}_{U_{S_k,v_0}}(v) \leq \text{outdeg}_{U_{S_k,v_0}}(v).$$

By Lemma 2.4, $D$ is $v_0$-reduced. \hfill $\Box$

**Example 2.7.** Let $\Gamma$ be a metric graph as illustrated in Figure 1(a) with a vertex set \{w_1, w_2, w_3, w_4\}. Let $D_1 = (v_1) + (w_3) + 2(w_4)$ and $D_2 = 2(v_1) + (v_2) + (w_3) + 2(w_4)$. Run Dhar’s algorithm for $D_1$ and $v_0$. The dashed areas in Figure 1(b) illustrate $U_{S_k,v_0}$ step by step. Initially, we have $S_0 = \{v_1, w_3, w_4\}$ and $U_{S_0,v_0} = \{v_1\} \cup \{w_3, w_4\}$. The set $N_0$ of all non-saturated boundary points of $U_{S_0,v_0}$ is $\{v_1, w_3\}$. Then $S_1 = S_0 \setminus N_0 = \{w_4\}$ and $U_{S_1,v_0} = \{w_4\}$. Since $w_4$ is a non-saturated point, we have $N_1 = \{w_4\}$ and $S_2 = \emptyset$. Now $U_{S_2,v_0}$ is the whole graph and we get the output $S = \emptyset$. Therefore $D_1$ is $v_0$-reduced. We leave it to the readers to verify the output of Dhar’s algorithm for $D_2$ and $v_0$ is $\{v_1, v_2, w_4\}$ and $D_2$ is not $v_0$-reduced (Figure 1(c)).

**Remark 2.8.** The out-degrees are topological invariants, which implies that whether or not a divisor is $v_0$-reduced is preserved under homeomorphisms.
2.2. **An algorithm for computing reduced divisors.** Based on Dhar’s algorithm and the criterion from Lemma 2.6, we formulate an algorithm to derive from an effective divisor $D$ the unique $v_0$-reduced divisor linearly equivalent to $D$.

Recall from [8] the notion of basic $v_0$-extremal functions on $\Gamma$. We say a rational function $f$ is a basic $v_0$-extremal function if there exist closed connected disjoint subsets $X_{\max}(f)$ and $X_{\min}(f)$ of $\Gamma$ such that:

(i) $v_0 \in X_{\min}(f)$;

(ii) $\Gamma - X_{\max}(f) - X_{\min}(f)$ is the union of disjoint open segments of the same length;

(iii) $f$ achieves its maximum on $X_{\max}(f)$ and its minimum on $X_{\min}(f)$;

(iv) $f$ has constant slope 1 from $X_{\min}(f)$ to $X_{\max}(f)$ on $\Gamma - X_{\max}(f) - X_{\min}(f)$.

**Definition 2.9.** Let $D$ be an effective divisor on $\Gamma$ and $S$ a subset of $\text{supp} D \setminus v_0$ such that all the boundary points of $\mathcal{U}_{S,v_0}$ are saturated with respect to $D$. Let $\Omega$ be a fixed vertex set of $\Gamma$. We call the following parameterizing process $\Delta_{D,S,v_0} : [0,1] \to \text{Div}_+ \Gamma$ the $v_0$-move of $D$ with respect to $S$ and $\Omega$: 

![Figure 1](image-url)
(i) \( \Delta_{D,S,v_0}^{(0)} = D \).

(ii) Let \( J \) be the number of connected components of \( \mathcal{U}_{S,v_0}^c \), and denote these components by \( X_1 \) through \( X_J \).

For \( j = 1, 2, \cdots, J \) and \( t \in (0, 1] \), let
\[
d_j^{(t)} = t \cdot \text{dist}(X_j, \mathcal{U}_{S,v_0} \cap (\Omega \cup v_0)),
\]
\[
P_j^{(t)} = \{ p \in \mathcal{U}_{S,v_0} \mid \text{dist}(X_j, p) = d_j^{(t)} \},
\]
\[
Q_j^{(t)} = \{ q \in \mathcal{U}_{S,v_0} \mid \text{dist}(X_j, q) \leq d_j^{(t)} \},
\]
and \( f_j^{(t)} \) a basic \( v_0 \)-extremal function such that
\[
X_{\text{max}}(f_j^{(t)}) = X_j, \text{ and } \partial X_{\text{min}}(f_j^{(t)}) = P_j^{(t)}.
\]

(iii) \( \Delta_{D,S,v_0}^{(t)} = D + \sum_{j=1}^{J} (f_j^{(t)}) \), for \( t \in (0, 1] \).

Example 2.10. Let \( \Gamma \) be the same metric graph as in Example 2.7 and \( D = D_2 \), as shown in Figure 2. In particular, we assign length 1 to all edges and let \( v_i \) be the middle point of the corresponding edge for \( i = 0, 1, 2, 3, 4 \). We know from Example 2.7 that the output \( S \) of Dhar’s algorithm for \( D \) and \( v_0 \) is \{\( v_1, v_2, w_4 \)\}. Let us consider a \( v_0 \)-move \( \Delta_{D,S,v_0} \). Note that \( \mathcal{U}_{S,v_0}^c \) has two connected components, \( v_1 \) and \( [v_2, w_4] \), which we denote by \( X_1 \) and \( X_2 \) respectively. We observe that \( d_1^{(t)} = d_2^{(t)} = 0.5t \) for \( t \in (0, 1] \). And at the end of the move \( t = 1 \), we get \( P_1^{(1)} = \{w_1, w_2\} \), \( Q_1^{(1)} = [w_1, v_1, w_2] \setminus v_1 \), \( P_2^{(1)} = \{v_3, v_4, w_3\} \), and \( Q_2^{(1)} = (w_4, v_3] \cup (w_4, v_4] \cup (v_2, w_3] \). In addition, \( (f_1^{(1)}) = (w_1) + (w_2) - 2(v_1) \) and \( (f_2^{(1)}) = (v_3) + (v_4) + (v_3) - (v_2) - 2(w_4) \). Then we get \( \Delta_{D,S,v_0}^{(1)} = D + (f_1^{(1)}) + (f_2^{(1)}) = (v_3) + (w_4) + (w_1) + (w_2) + 2(w_3) \).
Lemma 2.11. Let $D$ be an effective divisor which is zero at $v_0$ and $\Delta_{D,S,v_0}$ a move of $D$. Denote $\text{supp}\Delta_{D,S,v_0}^{(t)}$ by $O^{(t)}$ for $t \in [0, 1]$. Then $U_{O^{(t)},v_0}$ is non-expanding with respect to $t$. Moreover, $U_{O^{(t)},v_0}$ evolves continuously unless possibly undergoing an abrupt shrink at $t = 1$.

Proof. Let $Q_j^{(t)}$ be as defined in Definition 2.9 for $t \in (0, 1]$. Let $Q^{(0)} = \partial U_{S,v_0}$ and

$$Q^{(t)} = \bigcup_{j=1}^{J} Q_j^{(t)}, \text{ for } t \in (0, 1].$$

Clearly, $Q^{(t)}$ continuously expands with respect to $t$. For $t \in [0, 1)$, we have

$$U_{O^{(t)},v_0} = U_{O^{(0)},v_0} \setminus Q^{(t)},$$

which means $U_{O^{(t)},v_0}$ is non-expanding as $t$ increases and its evolution is continuous. The case $t = 1$ is somehow special, since the continuous expansion of $Q(t)$ might result in a hit at certain vertices or $v_0$. But we still have

$$U_{O^{(t)},v_0} \subseteq U_{O^{(0)},v_0} \setminus Q^{(1)}.$$  

This means that an abrupt shrink of $U_{O^{(t)},v_0}$ might happen at $t = 1$. \hfill \Box

Based on making $v_0$-moves iteratively, we propose the following algorithm to derive the $v_0$-reduced divisor linearly equivalent to an effective divisor $D$.

**Algorithm 2.12.** Input: An effective divisor $D \in \text{Div}_+, \Gamma$, and a point $v_0 \in \Gamma$.

**Output:** The unique $v_0$-reduced divisor $D_{v_0}$ linearly equivalent to $D$.

Initially, set $D^{(0)} = D$, and $i = 0$.

1. Run Dhar’s algorithm for $D^{(i)}$ and $v_0$ with the output denoted by $S^{(i)}$. If $S^{(i)} = \emptyset$, then set $D_{v_0} = D^{(i)}$ and stop the procedure. In addition, we say that the procedure terminates at $i$. And for convenience, we set $D^{(i)} = D^{(i)}$ for all real numbers $t > i$. Otherwise, go to step (2).

2. Make the $v_0$-move $\Delta_{D^{(i)},S,v_0}$ of $D^{(i)}$ with respect to $S^{(i)}$. Let $D^{(i+1)} = \Delta_{D^{(i)},S,v_0}^{(t)}$ for $t \in (0, 1]$. Set $i \leftarrow i + 1$, and go to step (1).

If the procedure in Algorithm 2.12 terminates at $I$, then by Lemma 2.6, $D_{v_0}$ is $v_0$-reduced as desired, and the evolution of $D$ into $D_{v_0}$ is parameterized by $D^{(i)}$, $t \in [0, I]$. The main goal of this section is to prove such a procedure always terminates (Theorem 2.14), which means that we will always get to a reduced divisor using finitely many moves.

Lemma 2.13. We have the following properties of the parameterizing procedure in Algorithm 2.12:

(i) $D^{(t)}(v_0)$ is integer-valued, bounded, and non-decreasing with respect to $t$, and it can jump only when $t$ is an integer. In addition, there exists an integer $I_1$ such that $D^{(t)}(v_0) = D^{(I_1)}(v_0)$ for all $t \geq I_1$.

(ii) For a non-negative integer $i_0$, let $d = D^{(i_0)}(v_0)$ and $D_0^{(t)} = D^{(t)} - d \cdot (v_0)$. Then for all real numbers $t \geq i_0$, $U_{\text{supp}D_0^{(t)},v_0}$ is non-expanding with respect to $t$. In particular, $U_{\text{supp}D_0^{(t)},v_0}$ evolves continuously unless possibly undergoing an abrupt shrink when $t$ is an integer.
(iii) Denote $U_{\supp D^{(i)}}$ by $U(t)$. For $t \geq I_1$, let $K^{(t)} = \#\{\Omega \cap U(t)\}$, which counts the number of vertices in $U(t)$ after $D^{(i)}(v_0)$ reaches its maximum. Then $K^{(t)}$ is integer-valued, bounded, and non-increasing with respect to $t$, and it can jump only when $t$ is an integer. Furthermore, there exists an integer $I_2 \geq I_1$ such that $K^{(t)} = K^{(I_2)}$ for all $t \geq I_2$.

Proof. Clearly $D^{(i)}(v_0)$ is integer-valued. Note that $v_0 \notin S^{(i)}$ for any $i$, which implies that $D^{(i)}(v_0)$ is non-decreasing and can only change its value when $t$ is an integer. Moreover, $D^{(i)}(v_0)$ is bounded from below by $D(v_0)$ and from above by $\deg(D)$, which guarantees the existence of the finite integer $I_1$. Thus Property (i) holds.

$D^{(i)}_0$ has value 0 at $v_0$. Thus by Lemma 2.11 for $t \geq i_0$, $U_{\supp D^{(i)}_0}$ is non-expanding, and evolves continuously unless possibly undergoing an abrupt shrink when $t$ is an integer. In particular, whenever $v_0$ is hit by a move, $U_{\supp D^{(i)}_0}$ will always be empty afterwards. And Property (ii) is proved.

After $D^{(i)}(v_0)$ reaches its maximum at $t = I_1$, $v_0$ will never be hit anymore. The above argument implies that for $t \geq I_1$, $U(t)$ is non-expanding, and continuously evolves unless possibly undergoing an abrupt shrink when $t$ is an integer. It follows immediately that $K^{(t)}$ is integer-valued, and non-increasing with respect to $t$, while it only possibly changes when $t$ is an integer. Clearly $K^{(t)}$ is lower-bounded by 0, which also implies the existence of $I_2$ and finishes the proof of Property (iii).

Theorem 2.14. The procedure in Algorithm 2.12 always terminates.

Proof. We proceed by induction on $\deg(D)$. Clearly Theorem 2.14 holds when $\deg D = 0$ since this implies that $D = 0$. Now suppose $\deg(D) > 0$.

By Lemma 2.13(i), if $D^{(I_1)}(v_0) > 0$, then $D^{(i)}(v_0) > 0$ for all $t \geq 0$ and the result follows by induction (applied to $D^{(I_1)} - (v_0)$). Now we assume $D^{(I_1)}(v_0) = 0$. By Lemma 2.13(iii), there exists an integer $I_2$, such that $K^{(t)} = K^{(I_2)}$ for all $t \geq I_2$. We let $t \geq I_2$ in the remaining parts of the proof. Note that $U(t)$ might keep shrinking. However, such a shrink can never hit a vertex anymore, which also means that $U(t)$ evolves continuously for $t \geq I_2$. Let $X$ be a connected component of $U(I_2)$ and let $U_0$ be a subset of $U(I_2)$ derived by removing the interior of all the segments with one end open and the other end a vertex or $v_0$. Clearly $U_0$ is closed and connected. And $U(I_2) \setminus U_0$ is a union of some disjoint open segments. Denote by $E_X$ the set of these segments. For $e \in E_X$, we use $w_e$ to denote the end of $e$ on $X$. We say $e \in E_X$ is obstructed at $t$ if $\supp D^{(i)} \cap e \neq \emptyset$ or $w_e$ is saturated with respect to $D^{(t)}$ and $X$. Note that if an edge is obstructed at $t$, then it is obstructed at all $t' \geq t$.

We claim that there exists $e \in E_X$ that never becomes obstructed. Otherwise, there exists an integer $I_3$ such that for $t \geq I_3$, the component of $U(t)$ corresponding to $X$ has all its boundary points saturated. Then one additional move from Algorithm 2.12 will result in a hit at a vertex, which contradicts the minimality of $K^{(I_2)}$. So let $e$ be an element of $E_X$ that never becomes obstructed. Then $w_e$ does not belong to any output $S^{(i)}$ of Dhar’s algorithm for $D^{(i)}$ when $i \geq I_2$. So Algorithm 2.12 for $D^{(I_2)}$ terminates if and only if the algorithm for $D^{(I_2)} - (w_e)$ terminates, and the induction applies.

Remark 2.15. What should $X$ look like in the above proof? Since $X$ must contain non-saturated boundary points with respect to $D^{(I_2)}$, there are only two possibilities. $X$ can
be a single non-vertex point with $D^{(I_2)}(X) = 1$, or else $X^{(I_2)}$ must contain a vertex on its boundary.

**Remark 2.16.** We know from Riemann-Roch theorem that the rank of the divisor $n \cdot (v_0)$ as a function of $n$ can be arbitrarily large. Hence given a divisor $D$ (not necessarily effective) on $\Gamma$, there always exists a divisor $D'$ which is non-negative on $\Gamma \setminus v_0$ and linearly equivalent to $D$. In particular, [S] presents an algorithm to construct such a divisor $D'$ as the first step in the proof of the existence part of Theorem 2.3 (Theorem 10 in [S]). By running Algorithm 2.12 for $D' - D'(v_0) \cdot (v_0)$ and $v_0$, we can always obtain a $v_0$-reduced divisor $D''$ linearly equivalent to $D - D'(v_0) \cdot (v_0)$. Then $D'' + D'(v_0) \cdot (v_0)$ is a $v_0$-reduced divisor linearly equivalent to $D$. This provides an alternative proof of the existence part of Theorem 2.3.

**Corollary 2.17.** Let $D$ be a divisor on $\Gamma$ and $|D|$ the linear system associated to $D$. For $v_0 \in \Gamma$, let $D_{v_0}$ be the unique $v_0$-reduced divisor $D_{v_0}$ in $|D|$.

(i) If $v_0 \in \text{supp}|D|$, then $D_{v_0}(v_0) > 0$.

(ii) If $|D| \neq \emptyset$ and $v_0 \notin \text{supp}|D|$, then $U_{\text{supp}D_{v_0},v_0}$ is nonempty and for all $v \in U_{\text{supp}D_{v_0},v_0}$, we have $v \notin \text{supp}|D|$ and $D_{v_0}$ is also $v$-reduced.

**Proof.** If $v_0 \in \text{supp}|D|$, let $D'$ be an effective divisor such that $D' \in |D|$ and $D'(v_0) > 0$. Applying Algorithm 2.12 for $D'$ and $v_0$, we can derive $D_{v_0}$. Note that $D_{v_0}(v_0) \geq D'(v_0)$. Thus $D_{v_0}(v_0) > 0$.

If $|D| \neq \emptyset$ and $v_0 \notin \text{supp}|D|$, then $D_{v_0}(v_0) = 0$, which means $U_{\text{supp}D_{v_0},v_0}$ is nonempty. For all $v \in U_{\text{supp}D_{v_0},v_0}$, clearly $D_{v_0}(v) = 0$, and using Dhar’s algorithm, it is easy to see that $D_{v_0}$ is also $v$-reduced. Moreover, we have $v \notin \text{supp}|D|$ by (i). □

**Remark 2.18.** In the sense of Corollary 2.17(ii), if $X$ is a subset of $U_{\text{supp}D_{v_0},v_0}$, then we may also say $D_{v_0}$ is $X$-reduced.

### 3. Rank-determining sets

We say a subset $\Gamma'$ of a metric graph $\Gamma$ is a **subgraph** of $\Gamma$ if $\Gamma'$ is connected and closed. Let $\Omega$ be a vertex set of $\Gamma$. Then $(\Omega \cap \Gamma') \cup \partial \Gamma'$ (considered in $\Gamma$) is automatically a vertex set of $\Gamma'$, which we call the vertex set of $\Gamma'$ induced by $\Gamma$. A **tree** on $\Gamma$ is a subgraph of $\Gamma$ with genus 0, and a **spanning tree** of $\Gamma$ is a tree on $\Gamma$ that is minimal among those which contain all vertices of $\Gamma$. We call a point $v$ a **cut point** in a metric graph if $\Gamma \setminus v$ is disconnected.

**3.1. A is a rank-determining set if and only if $\mathcal{L}(A) = \Gamma$.** For a nonempty subset $A$ of $\Gamma$, we use $\mathcal{L}(A)$ to denote a subset of $\Gamma$ such that $v \in \mathcal{L}(A)$ if and only if $A \subseteq \text{supp}|D|$ implies $v \in \text{supp}|D|$. For simplicity of notation, we denote $\mathcal{L}(\bigcup_{i=1}^{n} A_i)$ by writing $\mathcal{L}(A_1, A_2, \cdots, A_n)$. Note that we can always find a linear system whose support contains $A$ (for example, the support of the linear system associated to $\sum_{v \in \Omega}(v)$ is the whole graph $\Gamma$). Therefore

$$\mathcal{L}(A) = \bigcap_{\text{supp}|D| \supseteq A} \text{supp}|D|.$$ 

Obviously, $A \subseteq \mathcal{L}(A)$, and if $A'$ is a subset of $\mathcal{L}(A)$, then $\mathcal{L}(A, A') = \mathcal{L}(A)$. In case we want to emphasize that $A$ and all the linear systems are defined on $\Gamma$, we may write $\mathcal{L}_{\Gamma}(A)$ in stead of $\mathcal{L}(A)$.

**Proposition 3.1.** Let $A$ be a nonempty subset of $\Gamma$. The following are equivalent.
(i) $\mathcal{L}(A) = \Gamma$.
(ii) If $r_A(D) \geq 1$, then $r(D) \geq 1$.
(iii) $A$ is a rank-determining set of $\Gamma$.

Proof. (i)$\Leftrightarrow$(ii). $\mathcal{L}(A) = \Gamma$, if and only if $A \subseteq \supp|D|$ implies $\supp|D| = \Gamma$, if and only if $|D - E_1'| \neq \emptyset$ for all $E_1' \in \Div_+^1 A$, implies $|D - E_1| \neq \emptyset$ for all $E_1 \in \Div_+^1 \Gamma$, if and only if $r_A(D) \geq 1$ implies $r(D) \geq 1$.

(iii)$\Rightarrow$(ii). This follows directly from the definition of rank-determining sets.

(ii)$\Rightarrow$(iii). If $|D| = \emptyset$, then $r_A(D) = r(D) = -1$. We will only consider the case $|D| \neq \emptyset$ in the following. Since $A$ is a subset of $\Gamma$, it is easy to see that $r_A(D) \geq r(D)$ by definition. Therefore, to prove $A$ is a rank-determining set, it suffices to show that $r_A(D) \geq s$ implies $r(D) \geq s$ for each integer $s \geq 0$. The case $s = 0$ is trivial, since $\Div_+^0 A = \Div_+^0 \Gamma = 0$. And the case $s = 1$ is stated in (ii).

We claim that $r_A(D - E_k) \geq s - k, \forall E_k \in \Div_+^k \Gamma$, implies $r_A(D - E_{k+1}) \geq s - k - 1, \forall E_{k+1} \in \Div_+^{k+1} \Gamma$, for $s \geq 0$ and $k = 0, 1, \cdots, s - 1$. Equivalently, it says $|D - E_k - E_{s-k}'| \neq \emptyset, \forall E_k \in \Div_+^k \Gamma, \forall E_{s-k}' \in \Div_+^{s-k} A$, implies $|D - E_{k+1} - E_{s-k-1}'| \neq \emptyset, \forall E_{k+1} \in \Div_+^{k+1} \Gamma, \forall E_{s-k-1}' \in \Div_+^{s-k-1} A$, for $s \geq 0$ and $k = 0, \cdots, s - 1$. This can be proved by the following deduction:

$$r_A(D - E_k) \geq s - k, \forall E_k \in \Div_+^k \Gamma$$

$$\iff |D - E_k - E_{s-k}'| \neq \emptyset, \forall E_k \in \Div_+^k \Gamma, \forall E_{s-k}' \in \Div_+^{s-k} A$$

$$\iff |(D - E_k - E_{s-k-1}') - E_k'| \neq \emptyset, \forall E_k \in \Div_+^k \Gamma, \forall E_{s-k-1}' \in \Div_+^{s-k-1} A, \forall E_k' \in \Div_+^1 A$$

(By (ii))

$$\iff |(D - E_{k+1} - E_{s-k-1}) - E_k| \neq \emptyset, \forall E_k \in \Div_+^k \Gamma, \forall E_{s-k-1}' \in \Div_+^{s-k-1} A, \forall E_k \in \Div_+^1 \Gamma$$

$$\iff |D - E_{k+1} - E_{s-k-1}'| \neq \emptyset, \forall E_{k+1} \in \Div_+^{k+1} \Gamma, \forall E_{s-k-1}' \in \Div_+^{s-k-1} A$$

$$\iff r_A(D - E_{k+1}) \geq s - k - 1, \forall E_{k+1} \in \Div_+^{k+1} \Gamma.$$ 

Therefore, by applying the above deduction for $k$ going from 0 through $s - 1$, we have:

$$r_A(D) \geq s$$

$$r_A(D - E_1) \geq s - 1, \forall E_1 \in \Div_+^1 \Gamma$$

$$\cdots$$

$$r_A(D - E_{s-1}) \geq 1, \forall E_{s-1} \in \Div_+^{s-1} \Gamma$$

$$r_A(D - E_s) \geq 0, \forall E_s \in \Div_+^s \Gamma$$

$$r(D) \geq s.$$ 

Thus (ii) is sufficient to make $A$ a rank-determining set of $\Gamma$. \qed
3.2. Special open sets and a criterion for \( \mathcal{L}(A) \).

Definition 3.2. A connected open subset \( U \) of \( \Gamma \) is called a special open set on \( \Gamma \) if either \( U = \emptyset \) or \( \Gamma \), or every connected component \( X \) of \( U^c \) contains a boundary point \( v \) such that \( \text{outdeg}_X(v) \geq 2 \). In particular, we say \( \Gamma \) is trivial if \( U = \emptyset \) or \( \Gamma \). And we use \( S_\Gamma \) to denote the set of all special open sets on \( \Gamma \).

Lemma 3.3 through 3.7 present some simple properties of special open sets.

Lemma 3.3. Let \( U \) be a connected open set on \( \Gamma \), and \( D = \sum_{v \in \partial U} (v) \). Then \( U \) is a special open set if and only if \( D \) is \( U \)-reduced.

Proof. We just need to consider \( U \) nontrivial. And it follows directly by running Dhar’s algorithm for \( D \) and any point \( v \in U \).

Lemma 3.4. For \( v_0 \in \Gamma \), if \( D \) is a \( v_0 \)-reduced divisor, then \( \mathcal{U}_{\text{supp}\ D \setminus v_0} \) is a special open set.

Proof. Let \( D' = \sum_{v \in \text{supp}\ D \setminus v_0} (v) \). Since \( D \) is a \( v_0 \)-reduced divisor, \( D' \) must also be \( v_0 \)-reduced. Thus \( \mathcal{U}_{\text{supp}\ D \setminus v_0} \) is a special open set by Lemma 3.3.

Lemma 3.5. Let \( \Gamma \) be a metric graph of genus \( g \). If \( U \) is a nontrivial special open set on \( \Gamma \), then \( \overline{U} \) has genus at least 1. In addition, there exist at most \( g \) disjoint nonempty special open sets on \( \Gamma \).

Proof. If \( \overline{U} \) is a tree, then for every \( v \in \partial U \), \( \text{outdeg}_{\overline{U^c}}(v) = 1 \), which contradicts the definition of special open sets. And it follows immediately that \( \Gamma \) can sustain at most \( g \) disjoint nonempty special open set.

Lemma 3.6. Let \( X \) be a nonempty connected subset of \( \Gamma \), and \(|D|\) a linear system such that \( \text{supp}\ |D| \cap X = \emptyset \). Then there exists a special open set \( U \) such that \( X \subseteq U \subseteq (\text{supp}\ |D|)^c \).

Proof. Let \( v \in X \) and \( D' \) be the \( v \)-reduced divisor in \(|D|\). Then by Corollary 2.17 and Lemma 3.4, \( \mathcal{U}_{\text{supp}\ D'-v} \) is a special open set with the desired properties.

Lemma 3.7. Let \( D \) be a divisor on \( \Gamma \) and \(|D|\) the corresponding linear system. Then \((\text{supp}\ |D|)^c\) is a disjoint union of finitely many nonempty special open sets.

Proof. Let \( v_1 \) and \( v_2 \) be two points in \((\text{supp}\ |D|)^c\). Let \( D_1 \) and \( D_2 \) be elements of \(|D|\) that are \( v_1 \)-reduced and \( v_2 \)-reduced, respectively. Let \( U_1 = \mathcal{U}_{\text{supp}\ D_1-v_1} \) and \( U_2 = \mathcal{U}_{\text{supp}\ D_2-v_2} \). Then by Lemma 3.4, \( U_1 \) and \( U_2 \) are special open sets. In addition, we have either \( U_1 = U_2 \) or \( U_1 \cap U_2 = \emptyset \) by Corollary 2.17. Thus \((\text{supp}\ |D|)^c\) must be a disjoint union of nonempty special open sets. And we know from Lemma 3.5 that there are only finitely many of them.

Based on the notion of special open sets, we formulate a sufficient condition for \( v \) to belong to \( \mathcal{L}(A) \), as stated in the following theorem. (We will show in Theorem 3.16 that it is also a necessary condition.)

Theorem 3.8. Let \( v \in \Gamma \) and let \( A \) be a nonempty subset of \( \Gamma \). Then \( v \in \mathcal{L}(A) \) if for all special open sets \( U \) containing \( v \), we have \( A \cap U \neq \emptyset \). Moreover,

\[
\mathcal{L}(A) \supseteq \bigcap_{U \in S_\Gamma, U \cap A = \emptyset} U^c.
\]

In addition, \( A \) is a rank-determining set if all nonempty special open sets intersect \( A \).
Proof. Suppose \(|D|\) is a linear system such that \(A \subseteq \text{supp}|D|\). Then by Lemma 3.6 for every \(v \notin \text{supp}|D|\), there exists a neighborhood \(U\) of \(v\) which is a special open set disjoint from \(\text{supp}|D|\). Thus if all special open sets containing \(v\) intersect \(A\), then \(A \subseteq \text{supp}|D|\) implies \(v \in \text{supp}|D|\), which means \(v \in \mathcal{L}(A)\). It follows immediately that
\[
\mathcal{L}(A) \supseteq \bigcap_{U \in S_r, U \cap A = \emptyset} U^c.
\]

If all nonempty special open sets intersect \(A\), then \(\mathcal{L}(A) = \Gamma\). Thus \(A\) is a rank-determining set by Proposition 3.1. \(\square\)

**Proposition 3.9.** Let \(U\) be a nonempty connected open proper subset of \(\Gamma\) such that \(\overline{U}\) is a tree. Then \(\overline{U} \subseteq \mathcal{L}(\partial U)\).

Proof. \(\partial U\) is nonempty since \(U\) is a proper subset of \(\Gamma\). Then by Lemma 3.3 for every \(v \in U\), if \(U'\) is a critical open set containing \(v\), then \(\overline{U'}\) has genus at least 1 unless possibly \(U'\) is the whole graph. Thus \(U'\) must intersect \(\partial U\), since any connected closed subset of \(\overline{U}\) has genus 0. Therefore we have \(v \in \mathcal{L}(\partial U)\) by Theorem 3.8. \(\square\)

**Example 3.10.** (a) By Proposition 3.9 we immediately have \([w_i, w_j] \subseteq \mathcal{L}(w_i, w_j)\) for two adjacent vertices \(w_i\) and \(w_j\) (note that it doesn’t matter whether there are multiple edges between \(w_i\) and \(w_j\)). Thus \(\mathcal{L}(\Omega) = \Gamma\), which implies \(\Omega\) is a rank-determining set of \(\Gamma\), as claimed in Theorem 1.5.

(b) Let \(A\) be a finite set formed by choosing one internal point from each edge. Then it is also easy to show that \(A\) is a rank-determining set using Proposition 3.9.

**Proposition 3.11.** Let \(U\) be a nonempty connected open proper subset of a metric graph \(\Gamma\) such that \(\overline{U}\) has genus \(g'\). Let \(T\) be a spanning tree of \(\overline{U}\). Then \(U \setminus T\) is a disjoint union of \(g'\) open segments. Choosing one point from each of these segments, we get a finite set \(B\) of cardinality \(g'\). Then \(\overline{U} \subseteq \mathcal{L}(\partial U, B)\)

Proof. If \(g' = 0\), then \(\overline{U} \subseteq \mathcal{L}(\partial U)\) by Proposition 3.9. Now we suppose \(g' \geq 1\). Consider a point \(v \in U\). If \(v \notin \mathcal{L}(\partial U)\), then there exists a special open set \(U'\) such that \(v \in U'\) and \(U' \subseteq U\) by Theorem 3.8. We claim that \(U' \cap B \neq \emptyset\), which implies \(v \in \mathcal{L}(\partial U, B)\).

Denote the \(g'\) open segments of \(U \setminus T\) by \(e_1, e_2, \ldots, e_g\). If \(U' \cap T\) is not connected, then there must exist some \(e_i \subseteq U' \setminus T\) to make \(U'\) connected. Thus \(U' \cap B \neq \emptyset\). Now suppose \(U' \cap T\) is connected. By definition of special open sets, every connected component of \((U')^c\) contains a boundary point with out-degree at least 2, which means that there exists some \(e_i \subseteq U' \setminus T\) having one end in \(\partial U'\) and the other in \(U' \setminus T\). Thus we also have \(U' \cap B \neq \emptyset\). \(\square\)

**Remark 3.12.** Theorem 1.6 can be deduced from Proposition 3.11 by the following argument. Let \(\Gamma\) be a metric graph of genus \(g\) and \(T\) a spanning tree of \(\Gamma\). Choose an arbitrary point \(v_0\) from \(T\). Then \(\Gamma \setminus T\) is a disjoint union of \(g\) open segments \(e_1, e_2, \ldots, e_g\). Choose arbitrarily a point \(v_i\) from \(e_i\) for \(i = 1, 2, \ldots, g\). Let \(A = \{v_0, v_1, \ldots, v_g\}\). If \(v_0\) is not a cut point, then we can directly apply Proposition 3.11 to \(\Gamma \setminus v_0\) and conclude that \(\mathcal{L}(A) = \Gamma\). Otherwise, applying Proposition 3.11 to each connected component \(X\) of \(\Gamma \setminus v_0\) (note that the induced spanning tree of \(X\) is \(T \cap X\)), we also get \(\mathcal{L}(A) = \Gamma\). Therefore \(A\) is a rank-determining set of cardinality \(g + 1\) as desired.

**Remark 3.13.** We sketch Varley’s proof of Theorem 1.7 here. Consider a nonsingular projective algebraic curve \(C\). First note that the rank \(r(D)\) of a divisor \(D\) on \(C\) has the
same value as $\dim L(D) - 1$. Recall that we say a point $p \in C$ is a base point of a linear system $|D|$ if $p$ belongs to the support of every element of $|D|$, i.e., $p \in \text{BL}(|D|)$ where $\text{BL}(|D|) = \bigcap_{D' \in |D|} \text{supp}D'$ which is called the base locus of $|D|$. Varley’s argument uses the fact that a point $p \in C$ is a base point of $|D|$ if and only if $r(D - (p)) = r(D)$. (Note that this is not true for metric graphs.) Take any set $S$ of $g+1$ distinct points on $C$. To prove that $S$ is a rank-determining set, it suffices to show that for a divisor $D$ on $C$, if $r(D) \geq 0$, then there exists a point $p$ in $S$ such that $r(D - (p)) = r(D)$. Let $B = \sum_{q \in \text{BL}(|D|)}(q)$ which is the full base locus divisor of $|D|$. Note that $|B| = \{B\}$ since $B$ cannot “move”. If $\deg(B) \leq g$, then there is a point $p$ of $S$ not contained in $\text{BL}(|D|)$, which means $r(D - (p)) = r(D) - 1$. If $\deg(B) \geq g + 1$, then $r(B) \geq 1$ (by Riemann-Roch) which is impossible. The desired result follows by induction.

![Figure 3. A metric graph corresponding to $K_4$.](image)

**Example 3.14.** Let $\Gamma$ be a metric graph corresponding to $K_4$ with a vertex set $\Omega$ being $\{w_1, w_2, w_3, w_4\}$ as shown in Figure 3. Let $v_1, v_2, \ldots, v_6$ be some internal points. Clearly $\Omega$ itself is a rank-determining set by Theorem 1.5. But a proper subset of $\Omega$ can also be a rank-determining set. Note that $[w_1, w_3] \cup [w_2, w_3] \cup [w_4, w_3]$ is a spanning tree of $\Gamma$, which implies $w_3 \in \mathcal{L}(w_1, w_2, w_4)$ by Proposition 3.9. Thus $\{w_1, w_2, w_4\}$ is a rank-determining set as desired. It is also easy to see that $\{w_3, v_1, v_5, v_6\}$ and $\{v_1, v_3, v_5, v_6\}$ are rank-determining sets by Proposition 3.11. We recommend the reader to use Theorem 3.8 to verify that $\{v_1, v_2, v_3, v_4\}$ is another rank-determining set, which is not obvious at first sight.

**Proposition 3.15.** Let $U$ be a special open set on $\Gamma$. Then there exists a divisor $D$ such that $\text{supp}|D| = U^c$.

**Proof.** We only need to consider $U$ nontrivial. Assume $(\partial U)^c$ has $n$ connected components $X_1, X_2, \ldots, X_n$ other than $U$. Let $T_i$ be a spanning tree of $\overline{X_i}$, $i = 1, 2, \ldots, n$. Then $X_i \setminus T_i$ is a disjoint union of $g_i$ open segments. Choosing one point from each of these segments, we get a finite set $B_i$ of cardinality $g_i$. Let $B = \bigcup_{i=1}^n B_i$ and $D = \sum_{v \in \partial U} v + \sum_{v \in B}(v)$. Then by Proposition 3.11 we have $U^c = \bigcup_{i=1}^n \overline{X_i} \subseteq L(\partial U, B) \subseteq \text{supp}|D|$. Therefore, to prove $\text{supp}|D| = U^c$, it suffices to show that $D$ is $U$-reduced.

Let $D' = \sum_{v \in \partial U} v$. Then $D'$ is $U$-reduced since $U$ is a special open set. Thus by running Dhar’s algorithm for $D'$ and a point in $U$ step by step and taking the set of non-saturated
points in each step, we can get a partition of \( \partial U \) by \( N_0', N_1', \cdots, N_{K-1}' \). Note that for every \( X_i \), there exists some \( N_k' \) such that either \( \partial X_i \) is a subset of \( N_k' \) or \( X_i \) connects points in \( \partial X_i \cap N_k' \) and \( \partial X_i \cap N_{k+1}' \), i.e., \( \partial X_i \cap N_k' \) and \( \partial X_i \cap N_{k+1}' \) are nonempty and \( \partial X_i \subseteq N_k' \cup N_{k+1}' \). Therefore we may define a function \( \lambda : \{1, 2, \cdots, n\} \rightarrow \{1, 2, \cdots, K-1\} \) by \( \lambda(i) = k \) if \( \partial X_i \cap N_k' \neq \emptyset \) and \( \partial X_i \cap N_{k+1}' = \emptyset \). Let \( N_k = (\bigcup_{i=1}^{k} B_i) \cup N_k' \) for \( k = 0, 1, \cdots, K-1 \). Obviously these \( N_k \)'s form a partition of \( \partial U \cup B \). Running Dhar's algorithm for \( D \) and a point in \( U \) step by step, we observe that the set of non-saturated points in each step is precisely \( N_0, N_1, \cdots, N_{K-1} \) in sequence. Therefore the output is empty, which means \( D \) is \( U \)-reduced.

Now we come to the main conclusion of this subsection, which states that the condition in Theorem 3.8 is both necessary and sufficient.

**Theorem 3.16 (Criterion for \( \mathcal{L}(A) \)).** Let \( v \in \Gamma \) and let \( A \) be a nonempty subset of \( \Gamma \). Then \( v \in \mathcal{L}(A) \) if and only if for all special open sets \( U \) containing \( v \), we have \( A \cap U \neq \emptyset \). Furthermore,

\[
\mathcal{L}(A) = \bigcap_{U \in S_T, U \cap A = \emptyset} U^c.
\]

In addition, \( A \) is a rank-determining set if and only if all nonempty special open sets intersect \( A \).

**Proof.** We just need to prove that if \( v \in \mathcal{L}(A) \), then all critical open sets containing \( v \) must intersect \( A \).

Suppose for the sake of contradiction that there exists \( U \in S_T \) such that \( v \in U \) and \( A \cap U = \emptyset \). Then by Proposition 3.15, there exists a divisor \( D \) such that \( \text{supp}(D) = U^c \). Thus we have \( A \subseteq \text{supp}(D) \), which means that \( \mathcal{L}(A) \subseteq \text{supp}(D) \). But then \( v \not\in \mathcal{L}(A) \). \( \square \)

**Example 3.17.** Let \( \Gamma \) be a metric graph with a vertex set \( \{w_1, w_2, w_3\} \) as shown in Figure 4(a), and let \( v_1, v_2, v_3 \) be some internal points. Clearly \( [v_1, v_2] \subseteq \mathcal{L}(v_1, v_2) \). The dashed areas of Figure 4(b), \( U_1 \), \( U_2 \) and \( U_3 \), are three examples of special open sets disjoint from \( \{v_1, v_2\} \). Hence we have \( \mathcal{L}(v_1, v_2) = [v_1, v_2] \) by Theorem 3.16. Now let us consider \( \mathcal{L}(v_1, v_2, v_3) \). We observe that any special open set disjoint from \( \{v_1, v_2, v_3\} \) must be a subset of \( U_3 \), which implies \( \mathcal{L}(v_1, v_2, v_3) = U_3^c \).

### 3.3. Consequences of the criterion.

**Corollary 3.18.** Let \( A \) be a nonempty subset of \( \Gamma \). If \( A^c \) has \( n \) connected components \( X_1, X_2, \cdots, X_n \), then \( A \) is a rank-determining set if and only if \( X_i \subseteq \mathcal{L}(\partial X_i) \), for \( i = 1, 2, \cdots, n \).

**Proof.** For a point \( v \in X_i \), if a special open set \( U \) containing \( v \) intersects \( A \), then \( U \) must intersect \( \partial X_i \). Thus by Theorem 3.16, \( A \) is a rank-determining set, if and only if all nonempty special open sets intersect \( A \), if and only if for all \( v \in \Gamma \), if \( v \in X_i \), then all special open sets \( U \) containing \( v \) intersect \( \partial X_i \), if and only if \( X_i \subseteq \mathcal{L}(\partial X_i) \), for \( i = 1, 2, \cdots, n \). \( \square \)

**Corollary 3.19.** Let \( \Gamma \) be a metric graph with a cut point \( v \). Let \( \Gamma' \) the closure of a connected component of \( \Gamma \setminus v \). Then for a nonempty subset \( A \) of \( \Gamma' \), we have \( \mathcal{L}_{\Gamma'}(A) \subseteq \mathcal{L}_\Gamma(A) \).

**Proof.** For \( v' \in \Gamma' \), if \( v' \not\in \mathcal{L}_\Gamma(A) \), then there exists \( U \in S_T \) such that \( v' \in U \) and \( U \cap A = \emptyset \) by Theorem 3.16. Then \( U \cap \Gamma' \in S_T' \), which means \( v' \not\in \mathcal{L}_{\Gamma'}(A) \). \( \square \)
Figure 4. (a) A metric graph with a vertex set \( \{w_1, w_2, w_3\} \). (b) Three examples of special open sets disjoint from \( \{v_1, v_2\} \).

Proposition 3.20. Let \( \Gamma \) be a metric graph with a vertex set \( \Omega \) and \( A \) a finite rank-determining set of \( \Gamma \). Suppose there exists a point \( v \) in \( A \) which has degree \( m \geq 2 \) and is not a cut point of \( \Gamma \). Let \( U_v \) be an open neighborhood of \( v \) such that \( (U_v \setminus v) \cap (\Omega \cup A) = \emptyset \). Denote \( \Gamma - U_v \) by \( \Gamma' \). Then \( \Gamma' \) is a subgraph of \( \Gamma \) and \( A \setminus v \) is a rank-determining set of \( \Gamma' \).

Proof. \( \Gamma' \) is connected since \( v \) is not a cut point of \( \Gamma \) and \( U_v \setminus v \) contains no vertices. Thus \( \Gamma' \) is a subgraph of \( \Gamma \).

Clearly \( U_v \setminus v \) is a disjoint union of \( m \) open segments. Denote these open segments by \( e_1, e_2, \ldots, e_m \). Note that the total number of \( e_i \)'s ends other than \( v \) may be strictly less than \( m \) because of the existence of multiple edges.

Suppose \( A \setminus v \) is not a rank-determining set of \( \Gamma' \). Then there exists \( U' \in S_{\Gamma'} \) disjoint from \( A \) by Theorem 3.16. Without loss of generality, we assume that \( m' \) is an integer such that \( e_i \) has an end in \( U' \) for \( 1 \leq i \leq m' \) and \( e_i \) has no end in \( U' \) for \( m' < i \leq m \). Let \( U = U' \cup (\bigcup_{i=m'+1}^{m} e_i) \). Obviously \( U \) is a connected open set on \( \Gamma \) disjoint from \( A \). We claim \( U \in S_{\Gamma} \). This is because if \( m' < m \), then \( (\bigcup_{i=m'+1}^{m} e_i) \cup v \) may glue together some of the connected components of \( \Gamma' - U' \) into one connected component of \( \Gamma - U \) while the out-degrees of those boundary points are unchanged, and if \( m' = m \), then \( v \) itself forms a connected component of \( \Gamma - U \) and has out-degree at least 2. But this means \( A \) is not a rank-determining set of \( \Gamma \) by Theorem 3.16, a contradiction. \( \square \)

Remark 3.21. The converse proposition of Proposition 3.20 is not true. That is, \( A \) is not guaranteed to be a rank-determining set of \( \Gamma \) by \( A \setminus v \) being a rank-determining set of \( \Gamma' \). For example, let \( \Gamma \) be the metric graph corresponding to \( K_4 \) as shown in Figure 3. Let \( \Gamma' = [w_1, w_2] \cup [w_2, w_4] \cup [w_4, w_1] \). Then \( \{v_5, v_6\} \) is a rank-determining set of \( \Gamma' \). However \( \{v_5, v_6, w_3\} \) is not a rank-determining set of \( \Gamma \).
It is clear that special open sets are preserved under homeomorphisms since out-degrees are topological invariants. Thus Theorem 3.16 tells us that rank-determining sets are also preserved under homeomorphisms (Theorem 1.8). The following theorem provides a more general description of this fact.

**Theorem 3.22.** Let $f : \Gamma \to \Gamma'$ be a homeomorphism between two metric graphs $\Gamma$ and $\Gamma'$. Let $A$ be a nonempty subset of $\Gamma$. Then $L_{\Gamma'}(f(A)) = f(L_{\Gamma}(A))$. In particular, $A$ is a rank-determining set of $\Gamma$ if and only if $f(A)$ is a rank-determining set of $\Gamma'$.

For a closed segment $e$ on a metric graph $\Gamma$, we say $\phi_e : \Gamma \to \Gamma'$ is an edge contraction of $\Gamma$ with respect to $e$ if $\phi_e$ merges together all the points in $e$ into a single point while mapping every point in $\Gamma \setminus e$ to itself. Clearly an edge contraction $\phi_e$ may change the topology of $\Gamma$. We now give some some examples which show that rank-determining sets may not be preserved under edge contractions.

**Example 3.23.** (a) Consider a metric graph $\Gamma$ corresponding to $K_4$ as in Example 3.14. An edge contraction with respect to $[w_2, w_3]$ results in a new graph $\Gamma'$ (Figure 5(a)). Let $v_1', v_2', v_3', v_4', w_1', w_2', w_4'$ and $w'$ be the points in $\Gamma'$ corresponding to $v_1, v_2, v_3, v_4, w_1, w_4$ and $[w_2, w_3]$, respectively. We know that $\{v_1, v_2, v_3, v_4\}$ is a rank-determining set of $\Gamma$. However, as shown in Figure 5(a), $U$ is a critical open set disjoint from $\{v_1', v_2', v_3', v_4'\}$. Thus $\{v_1, v_2, v_3, v_4\}$ is not a rank-determining set of $\Gamma'$.
(b) Now let $\Gamma$ be the metric graph as in Example 3.17. By contracting $[w_1, w_2]$, we get a new graph $\Gamma'$ (Figure 5(b)). Let $v'_1, v'_2, w'_3$ and $w'$ be the points in $\Gamma'$ corresponding to $v_1, v_2, w_3$ and $[w_1, w_2]$, respectively. Note that $w' \in L_{\Gamma'}(v'_1, v'_2)$ by Corollary 3.19. Thus $\{v'_1, v'_2, w'_3\}$ is a rank-determining set of $\Gamma'$. However, $\{v_1, v_2, w_3\}$ is not a rank-determining set of $\Gamma$.

3.4. Minimal rank-determining sets.

**Definition 3.24.** We say that a rank-determining set $A$ of $\Gamma$ is minimal if $A \setminus v$ is not a rank-determining set for every $v \in A$.

It is easy to see from Proposition 3.9 that minimal rank-determining sets must be finite. In particular, the intersection of a minimal rank-determining set and an edge contains at most 2 points. We have the following criterion for minimal rank-determining sets as an immediate corollary of Theorem 3.16.

**Proposition 3.25.** Let $A$ be a subset of a metric graph $\Gamma$. Then $A$ is a minimal rank-determining set if and only if

(i) all nonempty critical open sets intersect $A$, and

(ii) for every point $v \in A$, there exists a special open set that intersects $A$ only at $v$.

![Figure 6. Two examples of special open sets on the metric graph corresponding to $K_4$.](image)

**Example 3.26.** Let us reconsider a metric graph corresponding to $K_4$ as in Example 3.14. The dashed areas of Figure 6, $U_1$ and $U_2$, are two special open sets. Let $A_1 = \{w_1, w_2, w_4\}$ and $A_2 = \{v_1, v_2, v_3, v_4\}$. By Example 3.14, $A_1$ and $A_2$ are both rank-determining sets. We will show that they are minimal rank-determining sets. Note that the points in $A_{1,2}$ are symmetrically distributed. Thus we only need to find some special open sets that intersect $A_1$ or $A_2$ at exactly one point by Proposition 3.25. We observe that $U_1 \cap A_1 = \{w_1\}$ and $U_2 \cap A_2 = \{v_1\}$. Thus $U_1$ and $U_2$ are the desired special open sets.

We’ve given a proof of Theorem 1.16 by showing constructively that a family of finite subsets of $\Gamma$, all having cardinality $g + 1$, are rank-determining sets. Now we will prove that these rank-determining sets are minimal.

**Proposition 3.27.** Let $\Gamma$ be a metric graph of genus $g$ and let $T$ be a spanning tree of $\Gamma$. Denote the $g$ disjoint open segments of $\Gamma \setminus T$ by $e_1, e_2, \ldots, e_g$. Choose arbitrarily a point $v_0$ from $T$ and a point $v_i$ from $e_i$ for $i = 1, 2, \ldots, g$. Let $A = \{v_0, v_1, \ldots, v_g\}$. Then $A$ is a minimal rank-determining set of $\Gamma$.
Proof. It suffices to find $g + 1$ special open sets $U_0, U_1, \ldots, U_g$ such that $U_i \cap A = \{v_i\}$ for $i = 0, 1, \ldots, g$ by Proposition 3.25.

Let $U_0 = \Gamma \setminus \{v_1, \ldots, v_g\}$. Clearly $U_0$ is connected and $U_0 \cap A = \{v_0\}$. It is easy to see that $U_0$ is a desired special open set. Now let us find the remaining $g$ special open sets as required. Without loss of generality, we only need to find $U_1$ for $v_1$. Let $u_a$ and $u_b$ be the two ends of $e_1$. Note that if $x$ and $y$ are two points (not necessarily distinct) in $T$, then there exists a unique simple path (no repeated points) on $T$ connecting $x$ and $y$, which we denote $\Lambda_{T, x, y}$. We observe that $\Lambda_{T, u_a, u_b} \cap \Lambda_{T, u_a, v_0} \cap \Lambda_{T, u_b, v_0}$ contains exactly one point, which we denote $u_c$. Let $U_1 = U_{\{u_c, v_2, \ldots, v_g, v_1\}}$. Then $U_1 \cap A = \{v_1\}$ and a connected component of $U_1$ is either a single point in $\{v_2, \ldots, v_g\}$ or a closed subset $X$ of $\Gamma$ with $u_c$ on its boundary such that $\text{outdeg}_X(u_c) = 2$. Thus $U_1$ is a special open set intersecting $A$ only at $v_1$. It follows that $A$ is a minimal rank-determining set of $\Gamma$. □

Our investigation shows that $g + 1$ appears to be an upper bound for the cardinality of minimal rank-determining sets, which we formulate as a conjecture here.

**Conjecture.** Let $\Gamma$ be a metric graph of genus $g$. Then every minimal rank-determining set of $\Gamma$ has cardinality at most $g + 1$.
