ERGODIC PROPERTIES OF VIANA-LIKE MAPS WITH SINGULARITIES IN THE BASE DYNAMICS

JOSÉ F. ALVES AND DANIEL SCHNELLMANN

Abstract. We consider two examples of Viana maps for which the base dynamics has singularities (discontinuities or critical points) and show the existence of a unique absolutely continuous invariant probability measure and related ergodic properties such as stretched exponential decay of correlations and stretched exponential large deviations.

1. INTRODUCTION

If \(\mu\) is an invariant measure for a map \(F : M \to M\), its basin is the set of all points \(x \in M\) such that
\[
\frac{1}{n} \sum_{i=0}^{n-1} \delta_{F^i(x)} \xrightarrow{\text{weak}^*} \mu, \quad \text{as } n \to \infty.
\]
Assuming \(M\) endowed with a Riemannian structure and a volume form extended to the Borel sets in \(M\) (Lebesgue measure), we say that an invariant probability measure \(\mu\)

is a *Sinai-Ruelle-Bowen (SRB) measure* if its basin has positive Lebesgue measure. It follows from Birkhoff Ergodic Theorem that ergodic absolutely continuous probability measures (acip) are necessarily SRB measures. Here, absolute continuity is always considered with respect to Lebesgue measure. We are interested in studying some statistical features of ergodic acips for certain classes of dynamical systems.

Let $B_1$ and $B_2$ denote Banach spaces of real valued measurable functions defined on $M$. We denote the *correlation* of non-zero functions $\varphi \in B_1$ and $\psi \in B_2$ with respect to a measure $\mu$ as

$$\text{Cor}_\mu(\varphi, \psi \circ F^n) := \frac{1}{\|\varphi\|_{B_1} \|\psi\|_{B_2}} \left| \int \varphi (\psi \circ F^n) \, d\mu - \int \varphi \, d\mu \int \psi \, d\mu \right|.$$ 

We say that we have *decay of correlations*, with respect to the measure $\mu$, for observables in $B_1$ against observables in $B_2$ if, for every $\varphi \in B_1$ and every $\psi \in B_2$ we have

$$\text{Cor}_\mu(\varphi, \psi \circ f^n) \to 0, \quad \text{as } n \to \infty.$$ 

Given $\varphi \in B_1$ and $\epsilon > 0$ we define the *large deviation* of $\varphi$ at time $n$ as

$$\text{LD}_\mu(\varphi, \epsilon, n) := \mu \left( \frac{1}{n} \sum_{i=0}^{n-1} \varphi \circ f^i - \int \varphi \, d\mu \right| > \epsilon \right).$$

By Birkhoff’s ergodic theorem the quantity $\text{LD}_\mu(\varphi, \epsilon, n) \to 0$, as $n \to \infty$, and a relevant question also in this case is the rate of this decay. In our main results we shall consider $B_1 = \mathcal{H}_\gamma$, the space of *Hölder continuous functions* with Hölder constant $\gamma > 0$. The Hölder norm of an observable $\varphi \in \mathcal{H}_\gamma$ is given by

$$\|\varphi\|_{\mathcal{H}_\gamma} = \|\varphi\|_\infty + \sup_{y_1 \neq y_2} \frac{|\varphi(y_1) - \varphi(y_2)|}{\text{dist}(y_1, y_2)^\gamma}.$$ 

In such cases we shall take $B_2 = L^\infty(\mu)$. In the proof of Theorem A we shall also consider $B_1$ as the space of *bounded variation functions* and $B_2$ as $L^1(\mu)$.

The purpose of this paper is to apply the theories developed in [ALP], [G], and [AFLV] to two examples of Viana maps studied in [S1] and [S2], and to deduce the existence of a unique absolutely continuous invariant probability measure and estimates for the Decay of Correlations and Large Deviations with respect to that measure. The Central Limit Theorem, the Almost Sure Invariance Principle, the Local Limit Theorem and the Berry-Esseen Theorem will also be deduced for our systems. Due to the technical nature of some of these concepts we introduce them in an appendix.

We shall consider skew-product maps similar to Viana maps. In one case with $\beta$-transformations as the base dynamics in the circle $S^1$, and in another case with a quadratic map as the base dynamics in an interval $I$. In the following let $Q_a(x) = a - x^2, x \in \mathbb{R}$, be a Misiurewicz-Thurston quadratic map, i.e., the parameter $a \in (0, 2)$ is chosen such that the critical point of $Q_a$ is pre-periodic (but not periodic). The full quadratic map $Q_2$ is excluded since we look at perturbations of the parameter $a$.

Furthermore, we assume that $Q_a$ is non-renormalizable.

1.1. *$\beta$-transformations in the base dynamics.* In [S1], the map under consideration is of the form $F_1 : S^1 \times \mathbb{R} \to S^1 \times \mathbb{R}$:

$$F_1(\theta, x) = (\beta \theta \mod 1, Q_a(x) + \alpha \sin(2\pi \theta)),$$

where $\beta$ is a real number greater or equal to some lower bound $\beta_a < 2$ (depending on the parameter $a$ of the quadratic map $Q_a$). This map is similar to the maps studied in [V] and [BST] but allowing a discontinuity in the base dynamics. If $p < 0$ denotes the
negative fixed point of $Q_a$, it is easy to check that there is an open interval $J \supset [p, -p]$ such that $F_1(S^1 \times J) \subset S^1 \times J$, whenever $\alpha > 0$ is sufficiently small.

For sufficiently small $\alpha > 0$, it is shown in [S1] that the map $F_1$ is non-uniformly expanding, and furthermore $F_1$ admits a unique acip for almost all $\beta \geq \beta_a$. In this paper we improve this result by showing that a unique acip exists, in fact, for all $\beta \geq \beta_a$. In addition, we obtain several statistical properties for this acip, such as stretched exponential decay of correlations and stretched exponential large deviations.

**Theorem A.** For all small enough $\alpha > 0$ and all $\beta > \beta_a$, the map $F_1 : S^1 \times J \to S^1 \times J$ admits a unique acip $\mu$ whose basin has full Lebesgue measure in $S^1 \times J$. Moreover,

1. there exist $C, \tau > 0$ such that $\text{Cor}_\mu(\varphi, \psi \circ F^n_1) \leq C e^{-\tau n^{1/3}}$ for all $\varphi \in \mathcal{H}_\gamma$ and all $\psi \in L^\infty(\mu)$;
2. for all $\epsilon > 0$ and all $\varphi \in \mathcal{H}_\gamma$ there exist $\tau' = \tau'(\varphi, \epsilon) > 0$ and $C' = C'(\varphi, \epsilon) > 0$ such that $L D_{\mu}(\varphi, \epsilon, n) \leq C' e^{-\tau' n^{1/3}}$;
3. the Central Limit Theorem, the vector-valued Almost Sure Invariance Principle, the Local Limit Theorem and the Berry-Esseen Theorem hold for certain Hölder observables.

**1.2. Quadratic maps in the base dynamics.** Let $Q_b(\theta) = b - \theta^2$, $\theta \in \mathbb{R}$ and $b \in (0, 2]$, be another Misiurewicz-Thurston map and set $I = [Q_b^2(0), Q_b(0)]$. The map studied in [S2] is of the form $F_2 : I \times \mathbb{R} \to I \times \mathbb{R}$:

$$F_2(\theta, x) = (Q_b^k(\theta), Q_a(x) + \alpha s(\theta)),$$

where $k \geq 1$ is an integer and $s : I \to [-1, 1]$ is a coupling function which is a priori not fixed. Again, if $p < 0$ denotes the negative fixed point of $Q_a$, it is easy to check that there is an open interval $J \supset [p, -p]$ such that $F_2(I \times J) \subset I \times J$ whenever $\alpha > 0$ is sufficiently small.

In [S2] it is shown that there is an integer $k_0 \geq 1$ and a family of (non-constant) coupling functions $s$ which are $C^2$ outside a finite number of singularities such that for each such coupling function $s$, all $k \geq k_0$, and all sufficiently small $\alpha$ the map $F_2$ is non-uniformly expanding. In fact, the only singularities for $s$ are square root singularities. Without loss of generality we assume that the map $Q_b$ is non-renormalizable from which follows that $Q_b^k$ has a unique acip for all $k \geq 1$. (Otherwise we can restrict the map $F_2$ to a smaller region $I \times R$ such that $Q_b^k : I \to I$ and $Q_b^k$ admits a unique acip).

In this paper we will show furthermore that $F_2$ admits a unique acip with the same statistical properties as for the map $F_1$.

**Theorem B.** For small enough $\alpha > 0$, the map $F_2 : I \times J \to I \times J$ admits a unique acip $\mu$ whose basin has full Lebesgue measure in $I \times J$. Moreover, there exists $\tau > 0$ such that for all $0 < \zeta < 1/9$

1. there exists $C > 0$ such that $\text{Cor}_\mu(\varphi, \psi \circ F_2^n) \leq C e^{-\tau n^{1/3}}$ for all $\varphi \in \mathcal{H}_\gamma$ and all $\psi \in L^\infty(\mu)$;
2. for all $\epsilon > 0$ and all $\varphi \in \mathcal{H}_\gamma$ there exist $\tau' = \tau'(\varphi, \epsilon) > 0$ and $C' = C'(\varphi, \epsilon) > 0$ such that $L D_{\mu}(\varphi, \epsilon, n) \leq C' e^{-\tau' n^{1/3}}$, where $\zeta' = \zeta/(\zeta + 2)$;
3. the Central Limit Theorem, the vector-valued Almost Sure Invariance Principle, the Local Limit Theorem and the Berry-Esseen Theorem hold for certain Hölder observables.

**1.3. Strategy.** To prove the first two items of Theorem A and Theorem B we will apply the result in [G] which shows the existence of a Young tower or Gibbs-Markov structure for the maps $F_1$ and $F_2$, with stretched exponential tail estimates for the
expansion and slow recurrence tails. These objects will be defined precisely in Section 2, and in Section 3 we obtain stretched exponential bounds on these tails. From the existence of such a tower it then follows the decay of correlations conclusions as stated in the two theorems. The conclusions on the large deviations are an immediate consequence of [AFLV, Theorem D(2)]. Finally, in Section 4 we obtain the topological transitivity of the maps, which assures the uniqueness of the acip in both cases.

The third items of Theorem A and Theorem B follow as a direct application of Corollaries B1-B4 in [AFLV].

2. Non-uniform expansion and slow recurrence

Let \( M \) be equal to \( M_1 = S^1 \times J \) or \( M_2 = I \times J \) and \( F : M \to M \) be equal to \( F_1 \) or \( F_2 \), respectively. Let \( S \) be some closed set of zero Lebesgue measure of singularities/criticalities such that \( F : M \setminus S \to M \) is a \( C^2 \) local diffeomorphism. We say that \( F \) is non-degenerate close to \( S \) if there are constants \( B > 1 \) and \( \xi > 0 \) such that the following three conditions hold. For all \( y \in M \setminus S \) and \( v \in T_y M \setminus \{0\} \), we have

\[
\text{(S1)} \quad \frac{1}{B} \, \text{dist}(y,S)^\xi \leq \frac{\|DF(y)v\|}{\|v\|} \leq B \text{dist}(y,S)^{-\xi};
\]

and for every \( y_1, y_2 \in M \setminus S \) with \( \text{dist}(y_1, y_2) < \text{dist}(y_1, S)/2 \), we have

\[
\text{(S2)} \quad \left| \log \|DF(y_1)^{-1}\| - \log \|DF(y_2)^{-1}\| \right| \leq B \frac{\text{dist}(y_1, S)}{\text{dist}(y_1, y_2)}; \\
\text{(S3)} \quad \left| \log |\det DF(y_1)^{-1}| - \log |\det DF(y_2)^{-1}| \right| \leq B \frac{\text{dist}(y_1, S)}{\text{dist}(y_1, y_2)}. 
\]

The critical or singular set \( S \) for the map \( F_1 \) is the set

\[
\{\{0\} \times J\} \cup \{S^1 \times \{0\}\},
\]

and the singular set \( S \) for the map \( F_2 \) is the set

\[
\left\{ \bigcup_{1 \leq i \leq m} \{b_i\} \times J \right\} \cup \{I \times \{0\}\},
\]

where the points \( \{b_1, ..., b_m\} \) consist of the critical points of \( Q^k_b \) and the points where the coupling function \( s \) is not \( C^2 \). It is straightforward to check that the map \( F_1 : M_1 \to M_1 \) satisfies the non-degeneracy conditions (S1)–(S3), where the constant \( \xi \) can be chosen equal to 1. Regarding the map \( F_2 : M_2 \to M_2 \), since the coupling function \( s \) has only square root singularities, one easily checks that the non-degeneracy conditions (S1)–(S3) hold for \( F_2 \) with \( \xi = 2 \).

The main result in [S1] and [S2], respectively, shows that the map \( F \) is non-uniformly expanding, i.e., there is some constant \( c > 0 \) such that for Lebesgue almost every \( y \in M \)

\[
\liminf_{n \to +\infty} \frac{1}{n} \sum_{j=0}^{n-1} \log \|DF(F^j(y))^{-1}\|^{-1} \geq c > 0.
\]

This implies that the expansion time function

\[
E(y) = \min \left\{ N \geq 1 : \frac{1}{n} \sum_{j=0}^{n-1} \log \|DF(F^j(y))^{-1}\|^{-1} \geq c/2, \text{ for all } n \geq N \right\},
\]

is defined and finite for Lebesgue almost every \( y \in M \). Given \( \delta > 0 \) we define the \( \delta \)-truncated distance from \( y \in M \) to \( S \) as \( \text{dist}_\delta(y,S) = \text{dist}(y,S) \) if \( \text{dist}(y,S) \leq \delta \) and
Hence, in order to show (4) it is sufficient to show that there exist constants
part of the argument is done in the proof of positive Lyapunov exponents, see [V]).
recurrence time function for the maps studied in [V] (also in their case, the essential
follow Section 6.2.1 in [AA] which establishes tail estimates of the expansion and
[S2] where the positivity of the Lyapunov exponents is shown. We can essentially
(6) 
\begin{align*}
\limsup_{n \to +\infty} \frac{1}{n} \sum_{j=0}^{n-1} -\log \text{dist}_\delta(F^j(y), \mathcal{S}) \leq \epsilon
\end{align*}
for Lebesgue almost every \( y \in M \). It follows that the recurrence time function
(3) \( R_{\epsilon,\delta}(y) = \min \left\{ N \geq 1 : \frac{1}{n} \sum_{j=0}^{n-1} -\log \text{dist}_\delta(F^j(y), \mathcal{S}) \leq 2\epsilon, \text{ for all } n \geq N \right\} \),
is defined and finite for a.e. \( y \in M \).
According to the results in [G], in order to prove Theorem A and Theorem B, it is
left to show that all the iterates of the map \( F \) are topologically transitive on the
attractor \( \Lambda = \bigcap_{n \geq 0} F^n(M) \) and that there exist constants \( \tau, \zeta > 0 \) such that for any
\( \epsilon > 0 \) there is \( \delta > 0 \) such that
(4) 
\begin{align*}
|\{y \in M : \mathcal{E}(y) > n \text{ or } R_{\epsilon,\delta}(y) > n\}| \leq O(e^{-\tau n^\zeta}),
\end{align*}
where \( |.| \) stands for Lebesgue measure. By the technique in [G], if (4) is satisfied
for some constants \( \tau, \zeta > 0 \) then the same constants appear also in the decay of
correlations.

3. Stretched exponential bounds

The main part in the proof of the theorems is to establish the stretched exponential
bound in (4). We divide the singular sets of \( F_1 \) and \( F_2 \) into two parts. One part will
contain the singularities for which it is enough to study the base dynamics, and the
other part contains the critical points due to the quadratic map \( Q_a \). More precisely,
when considering \( F_1 \) let \( S_h = \{0\} \times J \) and \( S_v = S^1 \times \{0\} \) (the indices \( h \) and \( v \) stand for
horizontal and vertical, respectively). When considering \( F_2 \) let \( S_h = \bigcup_{1 \leq i \leq m} \{b_i\} \times J \)
and \( S_v = I \times \{0\} \).

Let \( R_{\epsilon,\delta,h} \) and \( R_{\epsilon,\delta,v} \) be defined in the same way as the set \( R_{\epsilon,\delta} \) (see (3)) but with
\( S \) in its definition replaced by \( S_h \) and \( S_v \), respectively. Obviously, we have
\begin{align*}
\{y \in M : \mathcal{E}(y) > n \text{ or } R_{\epsilon,\delta}(y) > n\} \subset \{y \in M : R_{\epsilon,\delta,h}(y) > n\} \cup \{y \in M : \mathcal{E}(y) > n \text{ or } R_{\epsilon,\delta,v}(y) > n\}.
\end{align*}

Hence, in order to show (4) it is sufficient to show that there exist constants \( \tau, \zeta > 0 \)
such that for any \( \epsilon > 0 \) there is \( \delta > 0 \) such that
(5) 
\begin{align*}
|\{y \in M : R_{\epsilon,\delta,h}(y) > n\}| \leq O(e^{-\tau n^\zeta}),
\end{align*}
and
(6) 
\begin{align*}
|\{y \in M : \mathcal{E}(y) > n \text{ or } R_{\epsilon,\delta,v}(y) > n\}| \leq O(e^{-\tau n^\zeta}).
\end{align*}

3.1. Bounds for the fiber maps. The main calculations here are done in [S1] and
[S2] where the positivity of the Lyapunov exponents is shown. We can essentially
follow Section 6.2.1 in [AA] which establishes tail estimates of the expansion and
recurrence time function for the maps studied in [V] (also in their case, the essential
part of the argument is done in the proof of positive Lyapunov exponents, see [V]).

We will treat the maps \( F_1 \) and \( F_2 \) simultaneously. In order to apply the results
in [S2], we first have to conjugate the function \( F_2 \) to a function denoted by \( \hat{F}_2 \). The
conjugation function \( \Phi : I \times J \to [-1,1] \times J \) is of the form \( \Phi(\theta, x) = (\varphi(\theta), x) \),
\( (\theta, x) \in I \times J \), where \( \varphi : I \to [-1,1] \) is analytic outside a finite number of singularities.
\( \varphi \) is obtained by integrating the density of the acip for \( Q \), from which follows that the singularities of \( \varphi \) are of square root type. The conjugation function \( \Phi \) is explained in detail in [S2, p. 2684]. The conjugated map \( \tilde{F}_2 = \Phi \circ F_2 \circ \Phi^{-1} \) has the form \( \tilde{F}_2 : [-1, 1] \times J \to [-1, 1] \times J: \)

\[
\tilde{F}_2(\theta, x) = (g(\theta), Q_a(x) + \alpha h(\theta)),
\]

where \( g = \varphi \circ Q_a^k \circ \varphi^{-1} : [-1, 1] \to [-1, 1] \) is analytic and uniformly expanding outside a finite set of singularities and \( h : [-1, 1] \to [-1, 1] \) is \( C^2 \) (extendable to a neighborhood of \([-1, 1]\)) with first derivative bounded away from 0. In the setting of the map \( F_1 \) let the base dynamics \( \theta \mapsto d\theta \mod 1 \) also be denoted by \( g \). Depending on the context, in the following let \( M \) denote either \( M_1 \) or \([-1, 1] \times J \), and the map \( F \) stands either for \( F_1 \) or \( \tilde{F}_2 \). We define inductively \( f_n(\theta, x), (\theta, x) \in M \). \( f_1(\theta, x) \) is equal to \( Q_a(x) + \alpha \sin(2\pi \theta) \) for \( F_1 \) and equal to \( Q_a(x) + \alpha h(\theta) \) for \( \tilde{F}_2 \). For \( n \geq 2 \), \( f_n \) is defined by the equation \( F^n(\theta, x) = (g^n(\theta), f_n(\theta, x)) \). In order to get the bound (6) of the tail of the expansion and recurrence time function, we have to study the returns of \( f_n(\theta, x) \) to 0.

Henceforth, we consider only points \((\theta, x) \in M \) whose orbit does not hit the critical set \( S_\varphi \). This is no restriction since the set of those points has full Lebesgue measure. For \( r \geq 0 \), set \( J(r) = \{ x \in I : |x| \leq \sqrt{\alpha e^{-r}} \} \), and for each integer \( j \geq 0 \), we define \( r_j(\theta, x) = \min \{ r \geq 0 : f_j(\theta, x) \in J(r) \} \).

In [S1] and [S2], for some given constant \( 0 < \kappa < 1/4 \), one considers \( G = \{ 0 \leq j < n : r_j(\theta, x) \geq \left( \frac{1}{2} - 2\kappa \right) \log \frac{1}{\alpha} \} \).

Fix some integer \( n \geq 1 \) sufficiently large (only depending on \( \alpha > 0 \)). From the estimates in [S1, equation (14)] and [S2, equation (23)], we deduce that if we take \( B_2(n) = \{ (\theta, x) \in M : \text{there is } 1 \leq j < n \text{ with } f_j(\theta, x) \in J(\sqrt{n}) \} \), then there is a constant \( \tau_2 > 0 \) such that

\[
|B_2(n)| \leq \text{const } e^{-\tau_2 \sqrt{n}}.
\]

Furthermore, there exists a constant \( c > 0 \) (only depending on the quadratic map \( Q_a \), and not on \( \alpha \)) such that

\[
\log |\partial_x f_n(\theta, x)| \geq cn - \sum_{j \in G} r_j(\theta, x), \text{ for } (\theta, x) \notin B_2(n),
\]

see [S1, equation (15)], [S2, equation (24)], and [V, p 75 & 76]. Let

\[
B_1(n) = \left\{ (\theta, x) \in M : \sum_{j \in G} r_j(\theta, x) \geq \frac{c}{2} n \right\}.
\]

It is shown in [S1, equation (17)] and [S2, equation (25)] that there is \( \tau_1 > 0 \) such that

\[
|B_1(n)| \leq \text{const } e^{-\tau_1 \sqrt{n}}.
\]

Since the base dynamics of \( F \) is uniformly expanding, we obtain immediately that

\[
|\{ y \in M : \mathcal{E}(y) > n \}| \leq |B_1(n) \cup B_2(n)| \leq O(e^{-\tau \sqrt{n}}),
\]

where \( \tau = \min\{\tau_1, \tau_2\} \). Note that while the base dynamics \( g \) of \( \tilde{F}_2 \) is uniformly expanding the base dynamics \( Q_b^k \) of \( F_2 \) is not. However \( Q_b^{nk} = \varphi^{-1} \circ g^n \circ \varphi \) and, by the
we make this more precise. Consider the projection of $S$ that
\[ |\{ \theta, x \} | \text{ for all } (\zeta, \nu). \]
where the constant $\lambda$ exists such that $|D \varphi \eta^n(\theta)| \geq \lambda^n$ for all $\theta$ outside an exceptional set whose size is decreasing exponentially in $n$. It follows that the tail estimate (8) of the expansion time function does not only hold for the maps $F_1$ and $\tilde{F}_2$ but also for the map $F_2$.

From the arguments in [S1], [S2], and [V] it is obvious that the constant $c$ in the definition of $B_1(n)$ can be chosen arbitrarily small. Observe that in the set $B_1(n)$ we are only concerned about the returns of $f_n(\theta, x)$ to the set $J((1/2 - 2\kappa)\log (1/\alpha))$. Hence, setting

$$\delta = \frac{|J((1/2 - 2\kappa)\log (1/\alpha))|}{2} = \alpha^{1-2\kappa},$$

and writing $\epsilon$ instead of $c/2$, we obtain

$$\sum_{j=0}^{n-1} - \log \text{dist}_\delta(F^j(\theta, x), S_v) = \sum_{j \in G} r_j(\theta, x) \leq \epsilon n,$$

for all $(\theta, x) \notin B_1(n) \cup B_2(n)$. Considering the map $F_2$ this implies that

$$\sum_{j=0}^{n-1} - \log \text{dist}_\delta(F_2^j(\theta, x), S_v) \leq \epsilon n,$$

for all $(\theta, x) \notin \Phi^{-1}(B_1(n) \cup B_2(n))$, where $\Phi = (\varphi, \text{id})$ is the conjugating function described above. Since the derivative of $\varphi^{-1}$ is bounded from above (see, e.g., [S2]), we obtain

$$|\Phi^{-1}(B_1(n) \cup B_2(n))| \leq \|D \varphi^{-1}\|_{\infty} |B_1(n) \cup B_2(n)| \leq \text{const } e^{-\tau \sqrt{n}}.$$

We conclude that for the maps $F_1$ and $F_2$ we have

$$|\{ y \in M : R_{\epsilon, \delta, v}(y) > n \}| \leq O(e^{-\tau \sqrt{n}}).$$

Altogether we proved for $F_1$ and $F_2$ the stretched exponential bounds required in (6) where the constant $\zeta$ can be taken equally to $1/2$.

### 3.2. Bounds for the base dynamics

Note that to prove the decay on $|\{ y \in M : R_{\epsilon, \delta, h}(y) > n \}|$ we only have to consider the base dynamics. For the sake of notation we make this more precise. Consider the projection of $S_h$ to the first coordinate. We denote this projection again by $S_h$, i.e., for the base dynamics $g_1$ of the map $F_1$ the critical set $S_h$ is equal to $0 \in S^1$ and for the base dynamics $g_2$ of the map $F_2$ the critical set $S_h$ is equal to $\{ b_1, ..., b_m \} \subset I$. For $y = (\theta, x) \in M_i$, $i = 1, 2$, we have

$$R_{\epsilon, \delta, h}(y) = R_{\epsilon, \delta, h}(\theta) := \min \left\{ N \geq 1 : \frac{1}{n} \sum_{j=0}^{n-1} - \log \text{dist}_\delta(g^j_1(\theta), S_h) \leq 2\epsilon, \text{ for all } n \geq N \right\},$$

where $\text{dist}_\delta$ is defined as above but restricted to $S^1$ or $I$, respectively. It follows that $|\{ y \in M : R_{\epsilon, \delta, h}(y) > n \}|$ is equal to $|\{ \theta \in S^1 : R_{\epsilon, \delta, h}(\theta) > n \}|J$ or $|\{ \theta \in I : R_{\epsilon, \delta, h}(\theta) > n \}|J$, respectively.

To establish the desired tail estimates of the recurrence time function for the base dynamics we follow the strategy of [AFLV, Theorem 4.2]. We begin by introducing...
some auxiliary functions. For \( \delta > 0 \), let

\[
\phi(\theta) = \begin{cases} 
- \log \text{dist}(\theta, S_h) & \text{if dist}(\theta, S_h) < \delta, \\
\frac{\log \delta}{\delta} (\text{dist}(\theta, S_h) - 2\delta) & \text{if } \delta \leq \text{dist}(\theta, S_h) < 2\delta, \\
0 & \text{if dist}(\theta, S_h) \geq 2\delta,
\end{cases}
\]

where \( \theta \) is in \( S^1 \) or \( I \), respectively. Observe that \( \phi \) has discontinuities at the singular set \( S_h \). Let \( \nu \) denote the unique acip for \( g_1 \) or \( g_2 \), respectively. We can choose \( \delta > 0 \) sufficiently small so that

\[
\limsup_{n \to +\infty} \frac{1}{n} \sum_{j=0}^{n-1} - \log \text{dist}_{\delta}(g_i^j(\theta), S_h) \leq \lim_{n \to +\infty} \frac{1}{n} \sum_{j=0}^{n-1} \phi(g_i^j(\theta)) = \int \phi d\nu \leq \epsilon,
\]

\( i = 1, 2 \). For all \( k > 0 \) we let

\[
A_k := \{ \theta : \phi(\theta) \geq k \}
\]

and define

\[
\phi_k(\theta) := \begin{cases} 
k, & \text{if } \theta \in A_k; \\
\phi(\theta), & \text{otherwise}.
\end{cases}
\]

The functions \( \phi_k \) and the sets \( A_k \) correspond to the functions \( \phi_{2,k} \) and \( A_{2,k} \) in [AFLV, Section 5], respectively.

3.2.1. \( \beta \)-transformations. We consider first the setting in the case of the map \( F_1 \). Let \( B \) denote the space of functions \( \varphi \) on \( S^1 \) with bounded variation and set

\[
\|\varphi\|_B := V_{S^1} \varphi + \|\varphi\|_{L^1(m)},
\]

where \( m \) denotes the Lebesgue measure on \( S^1 \). By [AFLV, Appendix C.1 and Corollary H (2)] we get that for all \( \varphi \in B \) and for every \( \epsilon > 0 \) there exists \( \tau(\varphi, \epsilon) > 0 \) and \( C(\varphi, \epsilon) \) such that

\[
LD_\nu(\varphi, \epsilon, n) = \nu \left( \frac{1}{n} \sum_{i=0}^{n-1} \varphi \circ g_i^1 - \frac{1}{n} \int \varphi d\nu \right) \geq \epsilon \leq C(\varphi, \epsilon) e^{-\tau(\varphi, \epsilon)n}.
\]

Furthermore, by [AFLV, Proposition 2.5 and Lemma 2.6], we get

\[
\tau(\varphi, \epsilon) \geq e^2(8(\|\varphi\|_\infty + C'(\|\varphi\|_B)^2)^{-1}.
\]

The constant \( C' \) is equal to \( 2 \sum_{i \geq 0} \xi(i) \), where \( \xi(i) \) is an upper bound for the decay of correlation for observables in \( B \) against \( L^1(\nu) \). By [AFLV, Appendix C.1 and Corollary H (1)], this decay is exponential and, hence, \( C' \) is finite. Regarding the constant \( C(\varphi, \epsilon) \), we derive from the proof of [AFLV, Proposition 2.5] that \( C(\varphi, \epsilon) \leq 2e^{(4\|\varphi\|_\infty)^{-1}} \). Since the function \( \phi \) is not of bounded variation we cannot apply (9) directly to \( \phi \). However, the functions \( \phi_k \) are of bounded variation and, according to [AFLV, equation 5.1], we have

\[
LD_\nu(\phi, 2\epsilon, n) \leq LD_\nu(\phi_k, \epsilon, n) + n\nu(A_k).
\]

Since the density of \( \nu \) is bounded from above, this immediately implies \( \nu(A_k) \leq \text{const} |A_k| \leq \text{const} e^{-k} \). Altogether we obtain,

\[
LD_\nu(\phi, 2\epsilon, n) \leq 2e^{(4\|\phi_k\|_\infty)^{-1}} e^{-2(8(\|\phi_k\|_\infty + C'(\|\phi_k\|_B)^2)^{-1}n + \text{const} ne^{-k}}.
\]

Observe that \( \|\phi_k\|_\infty = k \), \( V_{S^1} \phi_k = 2k \) and \( \|\phi_k\|_{L^1(m)} \) is bounded from above by a constant independent on \( k \). We derive that there is a constant \( C \) independent on \( k \) and \( \epsilon \) such that

\[
LD_\nu(\phi, 2\epsilon, n) \leq C(\epsilon e^{2C^{-1}k^{-2}n} + ne^{-k}).
\]
Choosing $k = n^{1/3}$, we get $LD_\nu(\phi, 2\epsilon, n) \leq O(e^{-\tau n^{1/3}})$ for some constant $\tau = \tau(\epsilon) > 0$. Since $-\log \text{dist}_\delta \leq \phi$, the density of $\nu$ is bounded away from zero (see, e.g., [AFLV, Appendix C.1]), and $\int \phi d\nu \leq \epsilon$, we finally obtain

$$|\{\theta \in S^1 : R_{\epsilon, \delta, h}(\theta) > n\}| \leq \text{const} \cdot LD_\nu(\phi, 2\epsilon, n) \leq O(e^{-\tau n^{1/3}}),$$

which implies (5) where $\zeta = 1/3$.

3.2.2. Quadratic maps. It is only left to consider the case of the map $F_2$. By, e.g., [KN], $(g_2, \nu)$ has exponential decay of correlations for functions of bounded variation only against $L^p(\nu)$, $p > 2$. Thus, we cannot apply the argument above for the map $g_1$ which gives a sharper result. However, by [G], it follows that $(g_2, \nu)$ has exponential decay of correlations for Hölder observables against $L^\infty(\nu)$. In order to apply [G], we need the existence of a tower with exponentially small tales. But this follows from [Y]. Moreover, by [S2], it follows that the density of $\nu$ is uniformly bounded away from 0 on its support. Thus, [AFLV, Proposition 4.1] implies that there exists $\tau > 0$ such that for any $0 < \zeta < 1/9$ and any $\epsilon > 0$ sufficiently small one has

$$LD_\nu(\phi, 2\epsilon, n) \leq O(e^{-\tau n^{\zeta}}).$$

This concludes the proof of (5) in the case of the map $F_2$.

Remark 1. For $(g_2, \nu)$, [KN] and [MN] show exponential large deviation estimates for observables of bounded variation and for Hölder observables, respectively. Thus, regarding the argument above for the map $g_1$ one might expect to get in (5) a constant $\zeta$ close to $1/3$. However, the constants in [KN] and [MN] for the exponential large deviation are not as explicit as in (9), which makes it difficult to apply their results to our setting.

4. Topological transitivity

Denote by $\Lambda$ the attractor $\bigcap_{n \geq 0} F^n(M)$. We say that $F$ is topologically transitive on the attractor $\Lambda$ if, for every non-empty open subsets $U$ and $V$ of $\Lambda$, there exists $n$ such that $F^{-n}(U) \cap V$ contains a non-empty open set. For the maps $F_i$, $i = 1, 2$, we have, by the same argument as in [AV, Lemma 6.1], that its attractor $\Lambda_i$ coincides with $F^n_i(M_i)$. In fact, for the later use we note that the argument in [AV] shows even that if $D$ is an interval with its boundary points sufficiently close to $Q^2_a(0)$ and $Q_a(0)$, respectively, then $F^n_i(S^1 \times D) = \Lambda_i$ and $F^n_i(I \times D) = \Lambda_2$.

The essential part here is done in [A]. By Sections 3.1 and 3.2 we know that $F_i : M_i \to M_i$, $i = 1, 2$, is non-uniformly expanding and slowly recurrent to the critical set. Hence, we can apply Lemma 4.3 in [A] and we get that there is a constant $\delta > 0$ only dependent on the constant $c$ from the non-uniform expansion (see equation (7)) and on the constant $\beta$ from the non-degeneracy condition such that the following holds. For every $\epsilon > 0$ there exists $n_1 = n_1(\epsilon) > 0$ such that for any ball $B \subset M_i$ of radius $\epsilon$ there is an integer $n \leq n_1$ such that $F^n(B)$ contains a ball of radius $\delta$. Recall that the constant $c$ and, thus, also the constant $\delta$ do not depend on $\alpha$. The following argument is similar to that in [AV, p. 29]. Recall that we defined $I = [Q^2_a(0), Q_b(0)]$. Since $Q_a$ and $Q_b$ are non-renormalizable, it follows that the supports of the acip's for $Q_a$ and $Q_b$ are equal to $[Q^2_a(0), Q_a(0)]$ and $I$, respectively. Since the critical points of $Q_a$ and $Q_b$ are eventually mapped into repelling periodic points and since $Q_a$ and $Q_b$ are conjugated to uniformly expanding maps (see, e.g., [S2, Proposition 2.2]), it follows that there is an integer $n_2 = n_2(\delta) > 0$ such that if $V \subset [Q^2_a(0), Q_a(0)]$ and $V' \subset I$ are intervals of length $\delta$ then $Q^2_a(V) = [Q^2_a(0), Q_a(0)]$ and $Q^2_b(V') = I$. Recall that if $D$ is an interval with its boundary points sufficiently close to $Q^2_a(0)$ and $Q_a(0)$,
respectively, then $F^3_1(S^1 \times D) = \Lambda_1$ and $F^3_2(I \times D) = \Lambda_2$. Since $F_1$ and $F_2$ depend continuously on $\alpha$, it follows that if $\theta \in S^1$, $\theta' \in I$, and $V, V'$ are intervals of length $\delta$ satisfying $\theta \times V \subset \Lambda_1$ and $\theta' \times V' \subset \Lambda_2$, then for $\alpha$ sufficiently small we have

$$F^{n+2}_1(\theta \times V) = \{g^{n+2}(\theta)\} \times \mathbb{R} \cap \Lambda_1,$$

and

$$F^{n+2}_2(\theta' \times V') = \{Q^{(n+2)k}(\theta')\} \times \mathbb{R} \cap \Lambda_2.$$

Altogether, we derive that for each $\epsilon > 0$ there is an integer $n_0 = n_0(\epsilon)$, such that if $B \subset \Lambda_i$, $i = 1, 2$, is a ball of radius $\epsilon$ then $F^{n_0}_i(B) = \Lambda_i$. Thus, we conclude that $F_i$ is topologically transitive on $\Lambda_i$. Obviously, this argument works also for arbitrary iterates of $F_i$.

**Appendix A. Limit Theorems**

Here we define the statistical properties of dynamical systems which are mentioned in the last items of Theorems A and B.

A.1. **Central Limit Theorem.** Let $\varphi \in \mathcal{H}_\varphi$ be such that $\int \varphi d\mu = 0$. Then

$$\sigma^2 = \lim_{n \to \infty} \frac{1}{n} \int \left( \sum_{i=0}^{n-1} \varphi \circ F^i \right)^2 d\mu \geq 0$$

(10)

is well defined. We say the Central Limit Theorem holds for $\varphi$ if for all $a \in \mathbb{R}$

$$\mu \left( \left\{ x : \frac{1}{\sqrt{n}} \sum_{i=0}^{n-1} \varphi \circ F^i(x) \leq a \right\} \right) \to \int_{-\infty}^{a} \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}} dx, \quad n \to \infty,$$

whenever $\sigma^2 > 0$. Additionally, $\sigma^2 = 0$ if and only if $\varphi$ is a *coboundary* ($\varphi \neq \psi \circ F - \psi$ for any $\psi \in L^2$).

A.2. **Local Limit Theorem.** A function $\varphi : M \to \mathbb{R}$ is said to be *periodic* if there exist $\rho \in \mathbb{R}$, a measurable $\psi : M \to \mathbb{R}$, $\lambda > 0$ and $q : M \to \mathbb{Z}$, such that

$$\varphi = \rho + \psi - \psi \circ F + \lambda q$$

almost everywhere. Otherwise, it is said to be *aperiodic*.

Let $\varphi \in \mathcal{H}_\varphi$ be such that $\int \varphi d\mu = 0$ and $\sigma^2$ be as in (10). Assume that $\varphi$ aperiodic (which implies that $\sigma^2 > 0$). We say that the Local Limit Theorem holds for $\varphi$ if for any bounded interval $J \subset \mathbb{R}$, for any real sequence $\{k_n\}_{n \in \mathbb{N}}$ with $k_n/n \to \kappa \in \mathbb{R}$, for any $u \in \mathcal{H}_\varphi$, for any measurable $v : M \to \mathcal{R}_{\epsilon, \delta}$ we have

$$\sqrt{n}\mu \left( \left\{ x \in M : \sum_{i=0}^{n-1} \varphi \circ F^i(x) \in J + k_n + u(x) + v(F^n x) \right\} \right) \to m(J) \frac{e^{-\frac{\epsilon^2}{2\sigma^2}}}{\sigma \sqrt{2\pi}}.$$

A.3. **Berry-Esseen Inequality.** If $F$ admits a Gibbs-Markov induced map of base $\Delta_0$ and return time function $R$, then for any $\varphi : M \to \mathbb{R}$ define $\varphi_{\Delta_0} : \Delta_0 \to \mathbb{R}$ by

$$\varphi_{\Delta_0}(x) = \sum_{i=0}^{R(x)-1} \varphi(F^i x).$$

Let $\varphi \in \mathcal{H}_\varphi$ be such that $\int \varphi d\mu = 0$ and $\sigma^2$ be as in (10). Assume that $\sigma^2 > 0$ and that there exists $0 < \delta \leq 1$ such that $\int |\varphi_{\Delta_0}|^2 \chi_{|\varphi_{\Delta_0}| > z} d\mu \lesssim z^{-\delta}$, for large $z$. If
\[ \delta = 1, \text{ assume also that } \int |\varphi_{\Delta_0}|^3 \chi_{|\varphi_{\Delta_0}| \leq d\mu} \leq C > 0 \text{ such that for all } n \in \mathbb{N} \text{ and } a \in \mathbb{R} \text{ we have } \]

\[
\left| \mu \left( \left\{ x : \frac{1}{\sqrt{n}} \sum_{i=0}^{n-1} \varphi \circ F^i(x) \leq a \right\} \right) - \int_{-\infty}^{a} \frac{1}{\sigma \sqrt{2\pi}} e^{-x^2/2\sigma^2} dx \right| \leq \frac{C}{n^{\delta/2}}.
\]

A.4. Almost Sure Invariance Principle. Given \( d \geq 1 \) and a Hölder continuous \( \varphi : M \to \mathbb{R}^d \) with mean zero, we denote

\[ S_n = \sum_{i=0}^{n-1} \varphi \circ F^i, \quad \text{for each } n \geq 1. \]

We say that \( \varphi \) satisfies an Almost Sure Invariance Principle if there exists \( \lambda > 0 \) and a probability space supporting a sequence of random variables \( \{S_n^*\}_n \) (which can be \( \{S_n\}_n \) in the \( d = 1 \) case) and a \( d \)-dimensional Brownian motion \( W(t) \) such that

1. \( \{S_n\}_n \) and \( \{S_n^*\}_n \) are equally distributed;
2. \( S_n^* = W(n) + O(n^{1/2-\lambda}) \), as \( n \to \infty \), almost everywhere.

Satisfying an ASIP is a strong statistical property that implies other limiting laws such as the Central Limit Theorem, the Functional Central Limit Theorem or the Law of the Iterated Logarithm.
