General Considerations

All chemicals and solvents were purchased and used without further purification. $^1$H, $^{13}$C and 2D NMR Spectra were recorded with a Bruker DRX 500 MHz or DPX 300 MHz spectrometer. $^1$H NMR spectra are referenced to tetramethylsilane (TMS) and chemical shifts are given as parts per million downfield from TMS. Coupling constants are reported to the nearest 0.1 Hz. Melting points were determined using a Griffin D5 variable temperature apparatus and are uncorrected. Microanalyses were obtained on a Carlo Erba Elemental Analyser MOD 1106 instrument. IR spectra were recorded with a Perkin–Elmer FTIR spectrometer and samples were analysed in the solid phase. Mass spectra (HRMS) were obtained with a Bruker maxis impact 3000 spectrometer using electrospray ionisation. LC-MS experiments were run on a Waters Micromass ZQ spectrometer. Analytical HPLC analysis was carried out on an Agilent Technologies 1260 Infinity on a gradient of 95-5% acetonitrile in water. Analytical TLC was performed on 0.2 mm silica gel 60 F254 precoated aluminium sheets (Merck) and visualised by using UV irradiation or, in the case of amine intermediates, by staining with ninhydrin solution. Flash chromatography was carried out on silica gel 60 (35–70 micron particles, FluoroChem). The convention used to assign the spectroscopic data and for naming compounds for this series of aromatic oligoamides has been described previously.$^{[1]}$ Additional side chain functionalities were assigned in the NMR as 2-3° denoting the central aromatic ring functionalised at the 3-position on an oxygen atom.

Synthetic Chemistry

Helix mimetics and associated monomer building blocks were synthesized following previously reported methodology according to Scheme S1 and is described in the following section whilst characterization is described from pg 40 and $^1$H NMR spectra and LC-MS analyses are provided from pg 71. Helix mimetics used in biophysical and cell based screens described in this work are given in table S1. Helix mimetics labelled with biotin or fluorescein are annotated as such and given the parent compounds number from which they were derived.
To label mimetics with a biotin probe, a synthesis of an appropriate tag was developed as illustrated in Scheme S2.

Scheme S2 Synthesis of a novel biotin azide for use in solid phase ‘click’ chemistry.

It was also necessary to obtain three additional alkyne tagged monomers (Fig. S1). These were synthesized using established methods.

Figure S1 – Structures of the alkyne-functionalised monomers used in ‘click’ chemistry reactions.
Solid-Phase Trimer Synthesis

Amino acid-loaded Wang resin (0.1 mmol) was swelled in anhydrous DMF (5 ml) 15 minutes prior to reaction. The monomers (0.5 mmol) were each dissolved in anhydrous CHCl₃ (10 ml) and pre-activated for coupling with Ghosez’s reagent (315 μl, 20% in CHCl₃, 0.48 mmol) for 1 hour at room temperature. The coupling reactions were carried out on a CEM Liberty microwave assisted automated peptide synthesiser. A small sample was removed and cleaved from the resin with TFA: CH₂Cl₂ (1:1, 1 ml) and analysed by LC-MS to confirm formation of the desired trimer; coupling reactions were assumed to have gone to completion.

‘Click’ Chemistry

The trimers on amino acid-loaded Wang resin were suspended in THF: H₂O (1:1, 1 ml) and the azide was added (1 equivalent) along with CuSO₄·5H₂O (10 mol%) and sodium ascorbate (20 mol%). The reaction mixture was stirred overnight at room temperature. The resin was then washed with H₂O (1 ml, 5 mins) and subjected to the cleavage protocol.

Cleavage

The cleavage step was carried out manually, in 1.5 ml ‘Extract-Clean’ polypropylene reservoirs fitted with 20 μm polyethylene frits (Alltech). The resin was transferred to the reservoir and washed with CH₂Cl₂ (1 ml, 5 mins) and diethyl ether (1 ml, 5 mins). A 1:1 mixture of TFA: CH₂Cl₂ was added and the mixture was stirred for 30 mins at room temperature and the contents collected and the procedure repeated. The resulting solution was concentrated affording the target compound.

**Biophysical and Cellular Analyses**

**Protein Expression and Fluorescence Anisotropy**

Expression of hDM2 and fluorescence anisotropy assays were performed as described previously. Expression of Bcl-xₗ and fluorescence anisotropy assays were performed as described previously. Expression of Mcl-1 and fluorescence anisotropy assays were performed as described previously. Direct binding assays were performed as described previously. Fluorescence anisotropy assays were performed in 384-well plates (Greiner Bio-one). Each
experiment was run in triplicate and the fluorescence anisotropy measured using a Perkin Elmer EnVisionTM 2103 MultiLabel plate reader, with excitation at 480 nm and emission at 535 nm (5 nM bandwidth). All experiments were performed in assay buffer: 40 mM phosphate buffer at pH 7.50, containing 200 mM NaCl and 0.02 mg mL\(^{-1}\) bovine serum albumin (BSA) and data analysed following previously published methods.\(^5,6\)

\(^{15}\)N HSQC NMR binding experiments

\(^{15}\)N HSQC NMR binding experiments were performed as described previously with 160 μM protein in phosphate buffer (100 mM sodium phosphate, 1 mM DTT, 2.5% glycerol and 5% DMSO).\(^6\)

Cell culture

U2OS, SJSA-1 and Saos-2 cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM) and RPMI-1640 media respectively supplemented with 10% foetal bovine serum, penicillin-streptomycin and 2 mM L-glutamine.

Cell Viability

Cells were plated in 96-well plates at 10\(^4\) cells/well 24 hours before compound addition. Compounds were added as 50 μM stocks in serum-free media (Opti-MEM, 100 μl) and the cells were incubated for 18 hours. 15 μl of Dye Solution (Promega Cell Titre 96\(^\circ\)) was added and the cells were incubated for 4 hours. 100 μl of Stop Solution (Promega Cell Titre 96\(^\circ\)) was added and the solutions were mixed using a multi-channel pipette. After incubating for 1 hour the absorbance of each well was measured at 570 and 600 nm.

High Content Screening Assay

Cells were plated into 96-well plates (Viewpoint plates, Perkin Elmer, MA) at 4000 cells/well using an xrd-384 Fluid X dispenser fitted with an 8 nozzle resin dispensing cassette at 300 rpm (Fluid X Ltd, Nether Alderley, UK). Plates were allowed to equilibrate at room temperature in a hood for 1 hr then incubated for 24 hrs at 37°C and 5% CO\(_2\) before media was replaced with serum-free media (Opti-MEM) prior to compound addition. Compound stocks (10 mM in DMSO) were diluted 1:100 with Opti-MEM and added to the plated cells at final concentrations of 10 and 20 μM giving a final DMSO percentage of 0.2%. Library addition was performed using a Bravo SRT liquid handling platform (Agilent Technologies, Wokingham, UK). Plates were assayed 48 hrs after compound addition using immunofluorescent staining and high-content imaging approaches as detailed below. Compound precipitation was visually assessed on addition and at imaging. Assays were developed and validated using Nutlin 3a and ABT-737 at a variety of concentrations.

Immunofluorescent staining of assay plates was carried out as follows. Media was discarded and cells rinsed in phosphate buffered saline (PBS), before fixation in 4% paraformaldehyde (SigmaAldrich) for 15 mins. Cells were permeabilized with 0.1% Triton X-100 (VWR) in PBS for 5 mins, cells were then rinsed in PBS and blocked in 1% milk (Marvel, Premier Foods, St Albans, UK) for 5 mins before the addition of antibodies against LC3B (SF10, Enzo Life Sciences) and caspase 3 (Abcam, ab13847) diluted in 1% milk for 1 hr at room temperature. Following PBS rinses, 10
cells were incubated at room temperature for an hour in the dark with 1% milk containing goat anti-mouse AlexaFluor 568 (Molecular Probes), goat anti-rabbit AlexaFluor 633 (Molecular Probes), 1 µg/mL DAPI (Molecular Probes) and AlexaFluor-488 conjugated Phalloidin (Molecular Probes). Following a final set of PBS washes, plates were scanned and images collected with an Operetta HTS imaging system (PerkinElmer) at 20x magnification with 11 fields of view (510 x 675 µm)/well. Images were then analysed with Columbus 2.2 (PerkinElmer).

During assay development statistical analysis (Student T-tests, Mann-Whitney U tests and Spermann Rank correlation) was carried out using GraphPad Prism 6.00 software (GraphPad Software, La Jolla, CA). Screening hits were identified by Z-scores calculated using the following formula where s is the positive control and c the negative controls:

\[ Z = \frac{(sample-value - \mu_c)}{\sigma_c} \]

with hits determined as an absolute Z-score of 2 or more, as this correlates to a P value of 0.045, and thus statistical significance.\(^7\) False positives were defined as any DMSO-treated well in which the absolute Z score was greater than 2 whilst false negatives were Nutlin 3a-treated wells which had an absolute Z score of less than 2 on three independent, randomly distributed test plates.

**Cell Lysis and Western blotting**

Cells were lysed with 100 µl of lysis buffer (50 mM Tris HCl pH 8.0, 150 mM NaCl, 1 mM EDTA and 0.5 % Nonidet P-40) and the lysate was analysed by SDS PAGE electrophoresis and probed with antibodies against p21 (C-19, Santa Cruz, sc-397), and GAPDH (6C5, Abcam, ab8245).

**Biotin-tag assays**

Cells were plated in 10 cm dishes 24 hours before compound addition. Cells were treated with 10 µM of the biotinylated trimers in Opti-MEM and incubated for 4 hours. Cells were lysed with 100 µl of lysis buffer (50 mM Tris HCl pH 8.0, 150 mM NaCl, 1 mM EDTA and 0.5 % Nonidet P-40). Cell lysate was incubated with Streptavidin-coated magnetic beads (Sigma Aldrich) for 2 hours at 4 °C, followed by extensive washing of the protein complexes. Complexes were denatured by SDS PAGE electrophoresis and probed with antibodies against hDM2 (C-18, Santa Cruz, sc-812), Mcl-1 (S-19, Santa Cruz, sc-819) and Bcl-X\(_L\) (H-62, Santa Cruz, sc-7195).
Figure S2 Additional HCS summary for mimetic library (a). Example images of the five compounds (10 and 20 μM) and controls of 0.2% DMSO and Nutlin-3a (2 and 5 μM) scale = 50 μm. DAPI staining is shown in the blue channel, caspase 3 is shown in red, LC3B as yellow and conjugated phalloidin shown in green.
Table S2a - Summary of the results from the high-content assays for helix mimetics 1-77. U2OS cells were treated with 2 different concentrations of the helix mimetics (10 and 20 µM) and cell number assessed.

**Figure S5** - Dose response curve for the inhibition of the p53/hDM2 interaction by mimetic 23 measured with fluorescence anisotropy. hDM2 and FITC-p53 were added to a dilution series of the mimetics to give final concentrations of 154.2 and 54.5 nM, respectively.
Figure S6 Dose response curve for the inhibition of the p53/hDM2 interaction by mimetics 74-77 measured with fluorescence anisotropy. hDM2 and FITC-p53 were added to a dilution series of the mimetics to give final concentrations of 154.2 and 54.5 nM, respectively.

The dimers showed interesting results in the competition assay. Three of the compounds show no inhibition up to 100 μM but one – compound 75 – disrupted the interaction with an IC$_{50}$ of 31 μM; this is not too surprising given that 75 has a naphthyl group as the C-terminal monomer but, as the isoleucine side chain might also participate in binding it is possible that the aromatic naphthyl group effectively mimics the tryptophan on p53 resulting in the observed activity. Supporting this hypothesis, dimer 77 also contains a naphthyl but was synthesized using glycine loaded Wang resin so does not possess enough side chains to mimic all of the ‘hot-spot’ residues on p53.

\textbf{1-Biotin-3-azidopropylamine}

D-Biotin (1 g, 4.10 mmol) and 3-azidopropan-1-amine (1.11 g, 8.20 mmol) were dissolved in MeOH (50 ml) and DIPEA (2.85 ml, 16.39 mmol). HBTU (3.10 g, 8.20 mmol) was then added and the reaction mixture was stirred overnight at room temperature. The solvent was removed in vacuo and the residue taken up in EtOAc and filtered. The isolated precipitate was washed with EtOAc and DCM and recrystallised from MeOH affording the desired product as a white solid (248 mg, 0.81 mmol, 20 %).
