Abstract This paper deals with the problem of distributed fault detection and isolation in multi-agent systems with disturbed high-order dynamics subject to communication uncertainties and faults. Distributed finite-frequency mixed $H_\infty / H_{\infty}$ unknown input observers are designed to detect and distinguish actuator, sensor and communication faults. Furthermore, an agent is capable of detecting not only its own faults but also faults in its neighbouring agents. Sufficient conditions are then derived in terms of a set of linear matrix inequalities while adding additional design variables to reduce the conservatism. A numerical simulation is carried out in order to demonstrate the effectiveness of the proposed approach.

Keywords Fault detection and isolation · Attack detection · Multi-agent systems · Networked systems · Unknown input observers · Linear matrix inequalities

1 Introduction

During the past couple of decades, multi-agent systems have received considerable amount of attention from researchers thanks to their wide range of potential applications in different areas, such as formation control, constellations in satellite systems [1,2], cooperative unmanned aerial vehicles [3], transport systems [4], power grids and mobile robots [5–7], to mention a few.

The growing size and complexity of such systems render their safe operation and reliability critical topics of research. Indeed, in order to achieve their mission, the agents communicate between themselves over a given network. Hence, their vulnerability does not only stem from the fact that each agent can be faulty at any given time instant but also from the fact that the communication links between them can be faulty or subject to an attack. Indeed, on top of actuator and sensor faults, MASs can be subjected to multiple types of cyber-attacks [8–13].

In fact, many cyber-attacks have recently occurred around the world. Some examples include: multiple power blackouts in some countries like Brazil [14], the attack on the water distribution system in Australia [15], the Stuxnet attack that took control of actuators...
and sensors in an Iranian nuclear facility prompting the replacement of thousands of failed centrifuges [16], the cyber-attack against an Ukrainian power grid [17], etc. Clearly, these types of malicious attacks aim at degrading or interrupting the operation of connected systems, exploit their aforementioned vulnerabilities and can have extremely detrimental effects, not only from a process point of view but also from an environmental and financial one as well. It is shown in [18] that information security techniques such as adding encryption and authentication schemes can help make some attacks more difficult to succeed, but that they are far from being sufficient against cyber-attacks. Indeed, these malicious attacks may go unnoticed and lead to erroneous behaviours in the overall MAS’s dynamics and compromising the mission. This makes understanding their effects on the MAS dynamics, modelling them, detecting them, identifying them as well as isolating them, important issues.

There is a multitude of ways to detect and isolate faults and cyber-attacks in MASs. The reader is referred to [19] for a recent comprehensive survey. Some works proposed centralised architectures to detect faults or attacks [20,21], due to their simplicity, whereby the analysis of all data is done by a central unit. However, in order to avoid long-distance data transmissions, reduce complexity and improve scalability, namely in larger systems, the detection and isolation process should be distributed.

A great deal of existing works in the literature either focuses on linear MASs [22–29], do not consider the effect of disturbances [22,30], or do not consider the effect of measurement and communication noise [23,31,32]. However, it is a well-known fact that disturbances and noise are practically inevitable. Furthermore, some works focus only actuator faults [23,29,31,33] or on sensor faults [25–27].

In [26,30,31,34], UIOs were used for fault detection. Nevertheless, most of the existing works on fault detection using UIOs consider that the generated residual signals are completely decoupled from the unknown input. Indeed, they usually require a strict rank condition to decouple the unknown input vector, which can be infeasible. In [31] for instance, an UIO residual-based scheme for nonlinear homogeneous MASs with actuator faults was proposed, where faults and disturbances were decoupled from the error dynamics assuming some rank conditions. In [26], UIOs were combined with the mixed $H_\infty$/$H_\infty$ method for fault detection purpose where only sensor faults were considered. Furthermore, the $H_\infty$ performance index method proposed therein, as well as in [25,27] for instance, is only applicable when the distribution matrix of the sensor faults is of full column rank. In our work, one contribution is to relax such condition using the finite-frequency approach introduced in [35]. Furthermore, in [27,36] for instance, multiple faults cannot occur in the MAS, which is a drawback, especially in large-sized MASs.

In [23,27–29,31], information from neighbouring FDI filters was transmitted among agents, which may weaken the distributed property of the detection scheme. Indeed, if and when an observer fails to accurately give an estimate at a given instant for an agent, all surrounding observers in its neighbourhood are compromised, which in turn compromises their respective neighbours’ observers, thus creating a destructive snowball effect that might lead to confusing results, trigger false alarms, etc. In our work, such drawback is removed since observers do not communicate between themselves.

Unlike [23,28,29,31], where the topology is assumed to be undirected, a directed communication graph is considered in this work. Additionally, the proposed scheme in this paper does not require knowledge beyond its 1-hop neighbourhood and is independent on the graph topology of the overall MAS, making it more scalable. Furthermore, as opposed to the detection filters proposed in [23,29,31,33] where their size increases as the graph topology grows, in the proposed scheme, the size of the filter is only limited to the size of the neighbourhood of each agent independently, hence improving the scalability and reducing the computational burdens.

Given the limitations discussed above with respect to the existing studies, the main contributions of this work are summarised as follows:

- A more general problem is studied where actuator, sensor and communication faults are considered in the robust detection and isolation process for Lipschitz nonlinear heterogeneous MASs with disturbances and communication parameter uncertainties, without global knowledge about the communication graph and under-directed graphs.
- A distributed finite-frequency mixed $H_\infty$/$H_\infty$ nonlinear UIO-based FDI scheme is designed such that actuator and sensor faults along with the communication faults are treated separately. Hence, the...
rank condition on the measurement fault distribution matrix as required by [27, 28] for instance is relaxed. Additionally, the scheme is capable of detecting and distinguishing multiple faults and attacks at a given time instant.

- Sufficient conditions in terms of a set of LMIs are provided for the proposed finite-frequency $\mathcal{H}_\infty$ UIO-based method, where the coupling between Lyapunov matrices and the observer matrices is avoided. This LMI characterisation enables to reduce conservatism by introducing additional design variables.

A brief comparison of the proposed method with some existing works in the literature is given in Table 1. To the best of the authors’ knowledge, a distributed finite-frequency mixed $\mathcal{H}_\infty$ UIO-based scheme for FDI in heterogeneous networked MASs subject to disturbances, noise, actuator faults, sensor faults and communication attacks, is investigated for the first time in this paper.

The rest of the manuscript is organised as follows. Section 2 presents the problem formulation and some preliminaries. The proposed finite-frequency $\mathcal{H}_\infty$ UIO-based method and the corresponding algorithms are laid out in Sect. 3. In Sect. 4, an illustrative example is given to show the effectiveness of the proposed scheme. Finally, some conclusions are inferred in Sect. 5.

Notations: Given a transfer function $T_{xy}(s)$ linking $y$ to $x$, its $\mathcal{H}_\infty$ norm is defined as

$$||T_{xy}||_\infty = \sup_{\omega} \sigma(T_{xy}(j\omega)).$$

where $\sigma$ is the maximum singular value of $T_{xy}(s)$. Its $\mathcal{H}_-$ index is defined as

$$||T_{xy}||_- = \inf_{\omega} \sigma(T_{xy}(j\omega)).$$

where $\sigma$ is the minimum singular value of $T_{xy}(s)$. For a square matrix $A$, $\text{He}(A) = A + A^*$ where the superscript $A^*$ corresponds to the conjugate of $A$. $\text{tr}(A)$ is the trace of $A$. $I_n$ and $0_n$ refer to a column of all entries 1 and an identity matrix, respectively, and of dimensions $n$. $0_{m \times n}$ denotes a null matrix of dimension $m \times n$. $\text{diag}(a_1, a_2, \ldots, a_n)$ denotes the diagonal matrix containing $a_1, a_2, \ldots, a_n$ on the diagonal. $\text{Blkdiag}(A_1, A_2, \ldots, A_n)$ denotes the block diagonal matrix with matrices $A_1, A_2, \ldots, A_n$ on the diagonal. $\text{Col}(A_1, A_2, \ldots, A_n)$ denotes the column block matrix $(A_1^T, A_2^T, \ldots, A_n^T)^T$. Throughout this paper, for a real square matrix $P \in \mathbb{R}^{n \times n}$, $P > 0$ implies that $P$ is symmetric and positive-definite.

2 Problem formulation

Consider a heterogeneous MAS composed of $N$ agents labelled by $i \in \{1, \ldots, N\}$ and described by the following uncertain dynamics

$$\begin{align*}
\dot{x}_i(t) &= A_i x_i(t) + B_{ui} u_i(t) + B_{di} d_i(t) + B_{fi} f_i(t) + \varphi_i(x_i(t)) \\
y_i(t) &= C_i x_i(t) + D_{di} d_i(t) + D_{fi} f_i(t)
\end{align*}$$

(1)

where $x_i \in \mathbb{R}^{n_x}$, $u_i \in \mathbb{R}^{n_u}$, $y_i \in \mathbb{R}^{n_y}$, $d_i \in \mathbb{R}^{n_d}$, $f_i \in \mathbb{R}^{n_f}$ are the state vector, the control input, the output, the $L_2$-norm bounded disturbances and noise, the actuator fault and the sensor fault signals, respectively. Matrices $A_i \in \mathbb{R}^{n_x \times n_x}$, $B_{ui} \in \mathbb{R}^{n_x \times n_u}$, $B_{di} \in \mathbb{R}^{n_x \times n_d}$, $B_{fi} \in \mathbb{R}^{n_x \times n_f}$, $C_i \in \mathbb{R}^{n_y \times n_x}$, $D_{di} \in \mathbb{R}^{n_y \times n_d}$, $D_{fi} \in \mathbb{R}^{n_y \times n_f}$ are known constant matrices. $\varphi_i(x_i(t)) \in \mathbb{R}^{n_x}$ is a known function representing the nonlinearity of agent $i$.

2.1 Graph theory and communication faults

The topology is represented by a directed graph $G = (\mathcal{V}, \mathcal{E})$, where $\mathcal{V} = \{1, \ldots, N\}$ is the node set and $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ is the edge set. It is described by an adjacency matrix $A \in \mathbb{R}^{N \times N}$ that contains positive weight entries. If information flows from node $j$ to $i$, then $a_{ij} > 0$, otherwise $a_{ij} = 0$. The neighbouring set of node $i$, denoted by $\mathcal{N}_i \subseteq \mathcal{V}$, is the subset of nodes that node $i$ can sense and interact with. Alternatively, one could note $\mathcal{N}_i = \{i_1, i_2, \ldots, i_{N_i}\} \subseteq \{1, \ldots, N\}$, where $N_i = |\mathcal{N}_i|$.

The measured outputs are exchanged between neighbouring agents. Hence, an agent $i$ receives from each neighbour $j \in \mathcal{N}_i$ its output (resp. input), corrupted by parameter uncertainties associated with the communication link between $i$ and $j$, $\Delta a_{ij}(t) \in \mathbb{R}$ and by faults due to link faults, packet losses or potential cyber-attacks denoted $f_{ij}^c(t) \in \mathbb{R}^{n_{f_{ij}}}$ (resp. $f_{ji}^c(t) \in \mathbb{R}^{n_{f_{ji}}}$), i.e.

$$\begin{align*}
z_{ij}(t) &= a_{ij}(1 + \Delta a_{ij}(t)) y_j(t) + D_{z_{ij}} f_{ij}^c(t), \\
u_{ij}(t) &= a_{ij}(1 + \Delta a_{ij}(t)) u_j(t) + D_{u_{ij}} f_{ij}^c(t),
\end{align*}$$

(2)

with $z_{ij}(t) = y_i(t)$ and $u_{ij}(t) = u_i(t)$. $D_{z_{ij}} \in \mathbb{R}^{n_y \times n_{f_{ij}}}$ and $D_{u_{ij}} \in \mathbb{R}^{n_u \times n_{f_{ij}}}$ are known constant

| [38]      | Yes    | No  | No            | No         | Yes     | Yes | No   | No   | No  |
| P. S.     | No     | Yes | Yes           | No         | Yes     | No  | No   | No   | No  |

matrices. It is also assumed that the parameter uncertainties \(\Delta a_{ij}(t)\) satisfy \(|\Delta a_{ij}(t)| < a_{ij}\).

Remark 1 It is worth noting that the considered faults cover a wide range of cyber-attacks that have been studied in the literature. For instance, assume that \(\Delta a_{ij}(t) = 0\) for the sake of clarity,

- In the case of a communication parametric fault \([30]\) for \(i\), affecting all its incoming information from agent \(j\), one has
  
  \[
  z_{ij}(t) = (a_{ij} + f_{a_{ij}}(t))y_{j}(t) \\
  = a_{ij}y_{j}(t) + f_{a_{ij}}(t)y_{j}(t),
  \]

  where analogously to (2), one could note that \(f_{a_{ij}}(t) = f_{a_{ij}}(t)y_{j}(t)\) and \(D_{z_{ij}} = I_{n_y}\). \(f_{a_{ij}}(t)\) represents a parametric fault affecting the communication parameter \(a_{ij}\).

- In a denial of service attack situation affecting all incoming information from agent \(j\), one has
  
  \[
  f_{z_{ij}}(t) = -a_{ij}\delta(t-t_{ij})y_{j}(t) \text{ and } D_{z_{ij}} = I_{n_y} \quad [39],
  \]

  where
  
  \[
  \delta(t-t_{ij}) = \begin{cases} 
  1, & t \geq t_{ij} \\
  0, & \text{else}
  \end{cases} ,
  \]

  and \(t_{ij}\) is the instant at which the attack occurs.

- Conversely, in a false data injection situation in the transmitted information, agent \(j\) transmits or receives fake/invalid information, that is, \(f_{z_{ij}}(t)\) contains the injected malicious information \([12]\). In the case where the malicious information \(f_{z_{ij}}(t) \in \mathbb{R}\) affects all incoming transmitted data equally, then one could set \(D_{z_{ij}} = I_{n_y}\).

- Under replay attacks, the attacker intercepts the transmitted information and replays it with a delay instead of the actual information. In this case, one could write \([10]\),
  
  \[
  f_{z_{ij}}(t) = \delta_{ij}(t-t_{ij})(-a_{ij}y_{j}(t) + y_{j}(t-T_{ij})) \text{ and } D_{z_{ij}} = I_{n_y},
  \]

  where
  
  \[
  \delta_{ij}(t-t_{ij}) = \begin{cases} 
  1, & t \geq t_{ij} \\
  0, & \text{else}
  \end{cases} ,
  \]

  and \(t_{ij} > 0\) is the instant at which the attack occurs and \(T_{ij} \in \mathbb{R}\) is the time delay.

The same remarks could be made w.r.t. \(u_{ij}(t)\). Contrary to agent/node attacks or faults in the form of the signals \(f_{a_{i}}(t), f_{s_{i}}(t)\), edge/communication attacks cannot be detected locally by an emitting agent \(j\) and thus need its neighbours to detect them. It is worth mentioning that the introduced problem can represent many potential practical applications to FDI in networked MASs. As discussed in introduction section, such applications include electric power networks and micro-grids, multi-robot and multi-vehicle systems, etc. \([37,38,40]\).

2.2 Concatenated local model

In this subsection, a concatenated model is developed for each agent. Let us first denote
A distributed fault detection scheme

If \( z \) with \( \bar{A} \), \( \bar{B}_s \), and \( \bar{B}_f \) correspond to the following tilde notation

\[
\bar{\Theta}_i = \begin{bmatrix}
\Theta_i & 0 & \ldots & 0 \\
-\Theta_i & 0 & \ldots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \ldots & -\Theta_i
\end{bmatrix},
\]

with \( \bar{A}_i \in \mathbb{R}^{n_i \times n_i} \), \( \bar{B}_{ui} \in \mathbb{R}^{n_u \times n_i} \), \( \bar{B}_{fi} \in \mathbb{R}^{n_u \times n_j} \), \( \bar{D}_{di} \in \mathbb{R}^{n_i \times n_j} \), \( \bar{D}_{fi} \in \mathbb{R}^{n_i \times n_j} \). Let us make the following assumption on the parametric uncertainties

**Assumption 1** There exist a time-varying matrix \( v_i(t) \in \mathbb{R}^{n_i \times n_i} \) and known matrices \( X_i \) and \( M_i \) with appropriate dimensions such that

\[
\Delta Z_i = X_i v_i(t) M_i,
\]

with \( \bar{\Theta} (v_i) \leq \delta M \).

**Remark 2** It is worth noting that this assumption stems from the definition of the graph topology in this paper and is standard for bounded uncertainties [41].

Under this assumption, one could rewrite system (5) as

\[
\begin{align*}
\dot{x}_i(t) &= \bar{A}_i x_i(t) + \bar{B}_{ui} u_i(t) + \bar{B}_{di} d_i(t) + \bar{B}_{fi} f_i(t) + \bar{\Theta}_i (v_i(t)) \\
\dot{z}_i(t) &= Z_i \bar{C}_i x_i(t) + Z_i \bar{D}_d d_i(t) + Z_i \bar{D}_f f_i(t)
\end{align*}
\]
Assumption 2 and isolating not only the agent’s own faults but also the design of residual generators for each agent is sensitive to all types of faults in spite of the presence of uncertainties using UIOs. Consider the following assumption and lemma are going to be described hereafter. Define the state estimation error as \( e_{vi}(t) = x_{vi}(t) - \hat{x}_{vi}(t) \). Then

\[
e_{vi}(t) = (I + H_i Z_i^T \tilde{C}_i)x_{vi}(t) - q_{vi}(t) + H_i V_{vi} V_{vi}(t),
\]

where \( D_i(t) = \left( \frac{d_{vi}(t)}{\phi(t)} \right) \), \( V_{vi} = (Z_i^T \tilde{D}_i - X_i \ D_{fi}) \) and \( v_i(t) = (D_i(t) / F_i(t)) \). Therefore, its dynamics is expressed as

\[
\dot{e}_{vi}(t) = N_i e_{vi}(t) + (T_i \tilde{A}_i - S_i Z_i^T \tilde{C}_i - N_i) x_{vi}(t) + T_i \phi e_{vi} \varepsilon_v_i + (T_i \tilde{B}_d - G_1) u_i(t) + S_i X_i \phi_i(t) - S_i D_{fi} F_i(t) + (T_i \tilde{B}_d - S_i Z_i \tilde{D}_d) d_{vi}(t) + T_i \tilde{B}_f f_{va}(t) + T_i \tilde{B}_u u_i(t) - G_2 z_i ((A_{i,i} \Delta A_{i,i} + A_{i,i}) u_i(t) + D_{ui} f_{ui}(t) + H_i V_{vi} V_{vi}(t)
\]

where

\[
T_i = I + H_i Z_i^T \tilde{C}_i,
\]

\[
S_i = L_i + N_i H_i,
\]

\[
\phi e_{vi} \varepsilon_v_i(t) = \phi_{vi}(x_{vi}(t)) - \phi_{vi}(\hat{x}_{vi}(t)),
\]

\[
\begin{align*}
\begin{cases}
 f_{ui}(t) = \text{Col}(f_{ii}(t), \ldots, f_{in}(t)), \\
 D_{ui} = \text{Blkdiag}(D_{ii}, \ldots, D_{in}), \\
 \Delta A_{i,i} = \text{diag}(\Delta a_{i1}, \ldots, \Delta a_{i1}, \ldots) \\
 A_{i,i} = \text{diag}(a_{i1}, \ldots, a_{i1}, \ldots)
\end{cases}
\end{align*}
\]

with \( v_i(t) = \Delta A_i \). By imposing the following

\[
H_i V_{vi}(t) = 0,
\]

\[
T_i \tilde{A}_i - S_i Z_i^T \tilde{C}_i = N_i,
\]

\[
T_i \tilde{B}_d - G_1 = 0,
\]

\[
T_i \tilde{B}_d - S_i Z_i \tilde{D}_d = 0,
\]

(9) becomes

\[
\dot{e}_{vi}(t) = N_i e_{vi}(t) + (T_i \tilde{B}_d - S_i Z_i^T \tilde{D}_d) d_{vi}(t) + T_i \tilde{B}_f f_{va}(t) - S_i D_{fi} F_i(t) + S_i X_i \phi_i(t) - T_i \tilde{B}_u ((A_{i,i}^{-1} A_{i,i}) \Delta A_{i,i} u_i(t) + N_i e_{vi}(t) + D_{ui} f_{ui}(t) + T_i \phi e_{vi} \varepsilon_v_i(t).
\]

3 Distributed fault detection and isolation scheme

The aim here is to design robust residual generators which are sensitive to all types of faults in spite of the presence of uncertainties using UIOs. Consider the following observer

\[
\begin{align*}
\dot{q}_{vi}(t) &= N_i q_{vi}(t) + G_{1i} u_i(t) + G_{2i} U_i(t) + L_i z_{vi}(t) + T_i \phi e_{vi}(\hat{x}_{vi}(t)) \\
\dot{\hat{x}}_{vi}(t) &= q_{vi}(t) - H_i z_{vi}(t) \\
\dot{\hat{x}}_{vi}(t) &= Z_i^T \tilde{C}_i \hat{x}_{vi}(t)
\end{align*}
\]

where \( U_i(t) = \text{Col}(u_{i1}(t), \ldots, u_{in}(t)) \). The matrices \( N_i, G_{1i}, G_{2i}, L_i, T_i \) and \( H_i \) will be described...
By setting new concatenated uncertainties vector as
\[ \overline{\phi}_{ij}(t) = \left( \phi_i(t) \right), \]
the error dynamics becomes
\[
\dot{e}_i(t) = N_ie_i(t) + \left( T_i \tilde{B}_{d_i} - S_i Z^j \tilde{D}_{d_i} \right) d_i(t) \\
+ T_i \Sigma_{e_i}(t) \\
- S_i D_i \mathbf{f}_i(t) + (S_i \tilde{X}_i - T_i \tilde{X}_i) \phi_i(t) \\
- T_i B_i \mathbf{f}_i(t),
\]
where \( B_i = \left( -\tilde{B}_i \tilde{B}_{u_i} A_{w_i,j}^{-1} D_{u_i} \right), \mathbf{f}_i(t) = \left( f_{ui}(t) \right), \)
\[ \tilde{X}_i = \left( X_i \ 0_{n_i \times (n_u - N_i)} \right), \tilde{X}_i = \left( 0_{n_i \times n_z - \tilde{B}_{u_i}} \right). \]

On the other hand, define the following residual vector
\[ r_i(t) = W_i(\xi_i(t) - \tilde{\xi}_i(t)), \]
where \( W_i \) is a pre-set post-residual gain matrix used to highlight the effects of the faults on the residual signals. In this work, since it does not directly affect the residual signals, it is considered that \( \mathbf{f}_i(t) \) affects the residual signals over a finite-frequency domain, which can be uniformly expressed as [44]
\[ \Omega_{\mathbf{f}_i} := \{ \omega_f \in \mathbb{R} | \kappa (\omega_f - \omega_f) (\omega_f - \omega_f) \leq 0 \}, \]
where \( \kappa \in \{ -1, 1 \}, \omega_f \) and \( \omega_f \) are given positive scalars characterizing the frequency range of the fault vector \( \mathbf{f}_i \). Indeed, if one selects
- \( \kappa = 1 \) and \( \omega_f < \omega_f \), then the set \( \Omega_{\mathbf{f}_i} \) corresponds to the middle frequency range
\[ \Omega_{\mathbf{f}_i} := \{ \omega_f \in \mathbb{R} | \omega_f < \omega_f \}. \]
- \( \kappa = 1 \) and \( -\omega_f = \omega_f \), then the set \( \Omega_{\mathbf{f}_i} \) corresponds to the low-frequency range
\[ \Omega_{\mathbf{f}_i} := \{ \omega_f \in \mathbb{R} | \omega_f \leq \omega_f \}. \]
- \( \kappa = -1 \) and \( -\omega_f = \omega_f \), then the set \( \Omega_{\mathbf{f}_i} \) corresponds to the high-frequency range
\[ \Omega_{\mathbf{f}_i} := \{ \omega_f \in \mathbb{R} | \omega_f \geq \omega_f \}. \]

The objective here is to simultaneously achieve local state estimation (asymptotic stability of the error dynamics) and fault/attack detection. Theorems 1, 2 and 3 are proposed in this section to solve this problem through a set of matrix inequalities using the \( \mathcal{H}_\infty, \mathcal{H}_- \) performance indexes. Hence, to summarise, the proposed fault/attack detection scheme is obtained through simultaneously satisfying the following, for some performance scalar variables \( \gamma_i, \epsilon_i, \beta_i \) and \( \delta_i \) \( \forall i \in \{ 1, \ldots, N \} \).

(i) To guarantee asymptotic stability of error dynamics (13).
(ii) To ensure a reasonable sensitivity of the residuals to the possible output attacks/faults over all frequency ranges, by satisfying
\[ ||T_r\mathbf{f}_i||_\infty > \gamma_i, \]
where \( r \) is the residual signal defined for the case with no disturbance \( d_i = 0 \), no uncertainty \( \phi_i = 0 \) and no fault \( \mathbf{f}_i = 0 \).

(iii) To ensure a reasonable sensitivity of the residuals to the possible input attacks/faults over a finite-frequency range defined in the set \( \Omega_{\mathbf{f}_i} \), by satisfying
\[ ||T_r\mathbf{f}_i||_\infty > \epsilon_i, \]
for all solutions of (13) such that,
\[ f_0 \int_{0}^{\infty} \left( \kappa (\omega_f e_i(t) + j \dot{e}_i(t)) (\omega_f e_i(t) - j \dot{e}_i(t))^T \right) dt \leq 0, \]
where \( \kappa, \omega_f, \omega_f \) are as defined in \( \Omega_{\mathbf{f}_i} \), and \( r_\mathbf{f}_i \) is the residual signal defined for the case with no disturbance \( d_i = 0 \), no uncertainty \( \phi_i = 0 \) and no fault \( \mathbf{f}_i = 0 \).

(iv) To guarantee a good disturbances and uncertainties rejection performance w.r.t. to the residual signals over all frequency ranges, i.e.
\[ ||T_r\mathbf{d}_i||_\infty \leq \eta_i, \]
where \( r_{\mathbf{d}_i} \) is the residual signal defined without fault \( \mathbf{f}_i = 0 \) and \( \mathbf{f}_i = 0 \).

For the rest of the manuscript, the time argument is omitted where it is not needed for clarity.

**Theorem 1** For \( d_i = 0, \phi_i = 0, \mathbf{f}_i = 0, \mathbf{f}_i \neq 0, \leq \gamma_i, \theta_{ui}, \sigma_i \) and \( \epsilon_i \) be strictly positive scalars, error dynamics (13) is asymptotically stable and performance index (16) is guaranteed if \( \forall i \in \{ 1, \ldots, N \} \), there exist symmetric positive definite matrices \( P_i \), matrices \( U_i, R_i \) and unstructured nonsingular matrices \( Y_i \) such that the following optimisation problem is solved

\[ \max_{P_i, Y_i, U_i, R_i} \gamma_i \]
**subject to**
\[
\begin{bmatrix}
\psi_i^1 \\
\psi_i^2 \\
\psi_i^3 \\
\psi_i^4 \\
0 \\
\psi_i^5 \\
-\epsilon_i I \\
\psi_i^6 \\
\end{bmatrix} < 0,
\]

\( \text{ Springer} \)
\[ U_i V_{vi} = 0, \] (21)

where

\[
\begin{align*}
\psi_i &= Y_i A_i + U_i Z_i^T C_i \tilde{A}_i - R_i Z_i^T \tilde{C}_i \\
&+ \tilde{A}_i^T Y_i^T + \tilde{A}_i^T (Z_i^T \tilde{C}_i)^T U_i - (Z_i^T \tilde{C}_i)^T R_i^T \\
&+ e_i \theta_{mi} I - (Z_i^T \tilde{C}_i)^T W_i W_i Z_i^T \tilde{C}_i, \\
\psi_i^2 &= -R_i D_{Fi} - (Z_i^T \tilde{C}_i)^T W_i^T W_i D_{Fi}, \\
\psi_i^3 &= Y_i + U_i Z_i^T \tilde{C}_i, \\
\psi_i^4 &= -Y_i + P_i + \sigma_1 \tilde{A}_i^T Y_i^T + \sigma_1 \tilde{A}_i^T (Z_i^T \tilde{C}_i)^T U_i^T \\
&- \sigma_1 (Z_i^T \tilde{C}_i)^T R_i^T, \\
\psi_i^5 &= -D_{Fi} W_i^T W_i D_{Fi} + \gamma_i^2 I, \\
\psi_i^6 &= -\sigma_1 D_{Fi} R_i^T, \\
\psi_i^7 &= \sigma_1 Y_i^T + \sigma_1 (Z_i^T \tilde{C}_i)^T U_i^T, \\
\psi_i^8 &= -\sigma_1 (Y_i + Y_i^T),
\end{align*}
\]

and the observer gains are specified as

\[
\begin{align*}
S_i &= Y_i^{-1} R_i, \\
H_i &= Y_i^{-1} U_i, \\
N_i &= (I + Y_i^{-1} U_i Z_i^T \tilde{C}_i) A_i - Y_i^{-1} R_i Z_i^T \tilde{C}_i, \\
G_{1i} &= (I + Y_i^{-1} U_i Z_i^T \tilde{C}_i) \tilde{B}_{ui}, \\
G_{2i} &= (I + Y_i^{-1} U_i Z_i^T \tilde{C}_i) \tilde{B}_{ui} A_i^{-1}, \\
L_i &= Y_i^{-1} R_i - N_i Y_i^{-1} U_i.
\end{align*}
\]

Proof Performance index (16) corresponds to the following function

\[
J_{\mathcal{F}_i} = \int_0^\infty \left( r_{iF_i}^2 + \gamma_i^2 r_{iF_i}^2 + \gamma_i^2 \right) dt > 0. 
\]

Let us select the candidate Lyapunov function

\[
V_i(e_{vi}) = e_{vi}^T P_i e_{vi},
\]

then

\[
\dot{V}(e_{vi}) = e_{vi}^T (N_i^T P_i + P_i N_i) e_{vi} + (\psi_i e_{vi})^T T_i^T P_i e_{vi}
\]

\[
+ e_{vi}^T P_i T_i \psi_i e_{vi} + \mathcal{F}_i^T (-S_i D_{Fi})^T P_i e_{vi}
\]

\[
+ e_{vi}^T P_i (-S_i D_{Fi}) \mathcal{F}_i.
\]

On the other hand, (23) can be expressed as

\[
J_{\mathcal{F}_i} = \int_0^\infty \left( \left( e_{vi}^T(t) (Z_i^T \tilde{C}_i) + \mathcal{F}_i^T(t) D_{Fi}^T \right) W_i^T W_i \\
+ (Z_i^T \tilde{C}_i e_{vi}(t) + D_{Fi} \mathcal{F}_i(t)) \\
- \gamma_i^2 \mathcal{F}_i^T \mathcal{F}_i - \dot{V}(e_{vi}) \right) dt
\]

\[
+ \int_0^\infty \dot{V}(e_{vi}) dt > 0.
\]

According to Assumption 2, it can be shown that

\[
(\psi_i e_{vi})^T e_{vi} = ||\psi_i e_{vi}||^2 \leq \theta_i^2 ||X_i(t) - \tilde{x}_i(t)||^2 \\
+ \theta_i^2 ||x_{i1}(t) - \tilde{x}_{i1}(t)||^2 + \cdots \\
+ \theta_i^2 ||x_{in}(t) - \tilde{x}_{in}(t)||^2 \\
\leq \theta_M e_{vi}^T e_{vi},
\]

where \(\theta_M = \max(\theta_1^2, \theta_2^2, \ldots, \theta_n^2)\).

Since \(V(e_{vi}) = e_{vi}^T P_i e_{vi} \geq 0\) and using Lemma 1 and equation (26), (25) can be shown to be equivalent to

\[
\left( T_i - P_i S_i D_{Fi} - (Z_i^T \tilde{C}_i)^T W_i^T W_i D_{Fi} \right) < 0,
\]

where \(T_i = N_i^T P_i + P_i N_i + e_i \theta_{Mi} I + e_i^{-1} P_i T_i T_i^T P_i - (Z_i^T \tilde{C}_i)^T W_i^T W_i Z_i^T \tilde{C}_i\). Using the Schur complement, (27) can be re-written as

\[
T_{ii} + \gamma_{ii} S_{ii} + S_{ii}^T \gamma_{ii}^2 < 0,
\]

with

\[
\gamma_{ii} = e_i \theta_{Mi} I - (Z_i^T \tilde{C}_i)^T W_i^T W_i Z_i^T \tilde{C}_i + (Z_i^T \tilde{C}_i)^T W_i^T W_i D_{Fi} + \gamma_i^2 I.
\]

Using the congruence transformation \((I \ T_{ii}^T)\), (28) is equivalent to

\[
\left( Y_{ii} + K_{1i} S_{ii} + S_{ii}^T K_{1i}^T \right) - K_{1i} + \gamma_{ii}^2 < 0,
\]

for new general matrices \(K_{1i}\) and \(\gamma_{ii}\). Hence, by selecting

\[
K_{1i} = (Y_{ii}^T 0 0), \quad \gamma_{ii} = \sigma_1 Y_{ii},
\]

for a scalar \(\sigma_1\) and a nonsingular general matrix \(Y_{ii}\), one can obtain the following sufficient condition

\[
\begin{pmatrix}
\Pi_1 & \Pi_2 & \Pi_3 \\
\Pi_2^T & \Pi_4 & \Pi_5 \\
0 & \Pi_4^T & \Pi_5 \\
\end{pmatrix} < 0,
\]

with

\[
\begin{align*}
\Pi_1 &= Y_{ii} N_i + N_i^T Y_{ii}^T + e_i \theta_{Mi} I \\
&\quad - (Z_i^T \tilde{C}_i)^T W_i^T W_i Z_i^T \tilde{C}_i, \\
\Pi_2 &= -Y_{ii} S_i D_{Fi} - (Z_i^T \tilde{C}_i)^T W_i^T W_i D_{Fi}, \\
\Pi_3 &= -Y_{ii} + P_i + \sigma_1 N_i^T Y_{ii}^T, \\
\Pi_4 &= -D_{Fi}^T W_i^T W_i D_{Fi} + \gamma_i^2 I, \\
\Pi_5 &= -\sigma_1 D_{Fi}^T S_{ii}^T \gamma_i^2.
\end{align*}
\]
Replacing $N_i$ and $T_i$ with their respective values, and applying the linearising change of variables $U_i = Y_i H_i, R_i = Y_i S_i$, (20) is obtained. Furthermore, pre-multiplying (11a) with $Y_i$ yields (21). Therefore, solving (20) under imposed constraints (21) and using observer gains (22) guarantees residual performance index (16) and the asymptotic stability of error dynamics (9).

**Theorem 2** For $d_{v_i} = 0, \phi_{j} = 0, \Sigma_{f} = 0, \Sigma_{j} \neq 0$, let $\varepsilon_i$, $\theta_i$, $\sigma_i$, and $E_i$ be strictly positive scalars, an arbitrary design matrix $K_i$, error dynamics (13) is asymptotically stable and performance index (17) is guaranteed if $\forall i \in \{1, \ldots, N\}$ over a finite-frequency domain defined in (15), there exist symmetric positive definite matrices $X_i$, symmetric matrices $X_i$, matrices $U_i$, $R_i$ and unstructured nonsingular matrices $Y_i$ such that the following optimisation problem is solved

$$
\max_{X_i, \Sigma_{f}, U_i, R_i} q_i
$$

subject to

$$
\begin{align*}
\begin{bmatrix}
\Sigma_{f}^1 & \Sigma_{f}^2 & \Sigma_{f}^3 & \Sigma_{f}^4 \\
\Sigma_{f}^5 & \Sigma_{f}^6 & \Sigma_{f}^7 \\
\Sigma_{f}^8 & \Sigma_{f}^9
\end{bmatrix} &< 0,
\end{align*}
$$

(30)

where

$$
\begin{align*}
\Sigma_{f}^1 &= Y_i \tilde{A}_i + U_i Z^T \tilde{C}_i \tilde{A}_i - R_i Z^T \tilde{C}_i + \tilde{A}_i^T Y_i^T \\
&\quad + (Z^T \tilde{C}_i \tilde{A}_i)^T U_i^T - (Z^T \tilde{C}_i \tilde{A}_i)^T R_i^T - \omega_{f,1} \omega_{f,2} X_i \\
&\quad + \varepsilon_i \theta_i I - (Z^T \tilde{C}_i \tilde{A}_i)^T W_i^T W_i Z^T \tilde{C}_i, \\
\Sigma_{f}^2 &= -U_i Z^T \tilde{C}_i B_i + \tilde{A}_i^T Y_i^T K_i^T \\
&\quad + (Z^T \tilde{C}_i \tilde{A}_i)^T U_i^T K_i^T - (Z^T \tilde{C}_i \tilde{A}_i)^T R_i^T K_i^T, \\
\Sigma_{f}^3 &= Y_i + U_i Z^T \tilde{C}_i, \\
\Sigma_{f}^4 &= -Y_i + X_i - j \omega_f X_i + \sigma_2 \tilde{A}_i Y_i^T \\
&\quad + \sigma_2 (Z^T \tilde{C}_i \tilde{A}_i)^T U_i^T - \sigma_2 (Z^T \tilde{C}_i \tilde{A}_i)^T R_i^T, \\
\Sigma_{f}^5 &= \varepsilon_i^T I - K_i Y_i B_i - K_i U_i Z^T \tilde{C}_i B_i \\
&\quad - B_i^T Y_i^T K_i^T - B_i^T (Z^T \tilde{C}_i \tilde{A}_i)^T U_i^T K_i^T, \\
\Sigma_{f}^6 &= K_i Y_i + K_i U_i Z^T \tilde{C}_i, \\
\Sigma_{f}^7 &= -K_i Y_i - \sigma_2 B_i Y_i^T - \sigma_2 B_i^T (Z^T \tilde{C}_i \tilde{A}_i)^T U_i^T, \\
\Sigma_{f}^8 &= \sigma_2 Y_i^T + \sigma_2 (Z^T \tilde{C}_i \tilde{A}_i)^T U_i^T, \\
\Sigma_{f}^9 &= -(X_i + \sigma_2 Y_i + \sigma_2 Y_i^T),
\end{align*}
$$

and $B_i = \left(-B_{f,1} \tilde{B}_{ui} A_{ui}^{-1} D_{ui}\right)$. The observer gains are then computed as in (22).

**Proof** Let us select the candidate Lyapunov function $V_i(e_{v_i}) = e_{v_i}^T X_i e_{v_i}$, then

$$
\dot{V}(e_{v_i}) = e_{v_i}^T (N_i^T X_i + X_i N_i) e_{v_i} + (\phi_{v_i})^T T_i^T X_i e_{v_i} \\
+ e_{v_i}^T X_i \tilde{A}_{v_i} e_{v_i} - \tilde{A}_{v_i}^T (T_i B_i) X_i e_{v_i} \\
- e_{v_i}^T X_i (T_i B_i) X_i (31)
$$

To solve (17) over a finite-frequency domain as defined in (15), one could define the following function

$$
J_{\Sigma_i} = \int_0^\infty \left( e_{v_i}^2 X_i^T e_{v_i} - r_i^T e_{v_i} - tr(He(W_i) X_i) \right) + \dot{V}(e_{v_i}) dr < 0.
$$

where $W_i = (\omega_{f,1} e_{v_i} + \tilde{r}_i e_{v_i})(\omega_{f,2} e_{v_i} + \tilde{r}_i e_{v_i})$ and $X_i$ is a symmetric matrix. From (18), one gets

$$
\int_0^\infty \kappa V_i dr < 0.
$$

Moreover, it can be shown through the Parseval’s theorem [45] that

$$
\int_0^\infty W_i dr = \frac{1}{2\pi} \int_0^{+\infty} \left((\omega_{f,1} - \omega)(\omega_{f,2} - \omega) - \omega \tilde{e}_i(\omega) \tilde{e}_i^T(\omega)\right) d\omega,
$$

where $\tilde{e}_i(\omega)$ is the Fourier transform of $e_{v_i}(t)$. Choosing $X_i$ such that $\kappa X_i \geq 0$, it yields

$$
tr((\int_0^\infty W_i dr) X_i) + tr((\int_0^\infty W_i dr) X_i) \leq 0,
$$

or equivalently, $tr(He(W_i) X_i) \leq 0$. Therefore, (17) is guaranteed for all solutions of (13) satisfying (18), if

$$
\int_0^\infty e_{v_i}^2 X_i^T e_{v_i} - r_i^T e_{v_i} + \dot{V}(e_{v_i}) - tr(He(W_i) X_i) < 0
$$

By setting $\omega_{fa} = \frac{\omega_{f,1} + \omega_{f,2}}{2}$, then

$$
- tr(He(W_i) X_i) = -e_{v_i}^T \omega_{fa} X_i e_{v_i} - e_{v_i}^T \omega_{fa} X_i e_{v_i} - e_{v_i}^T j \omega_{fa} X_i e_{v_i} \\
+ e_{v_i}^T j \omega_{fa} X_i e_{v_i} \\
= -e_{v_i}^T \omega_{fa} X_i e_{v_i} - e_{v_i}^T N_i^T X_i N_i e_{v_i} \\
- (\phi_{v_i})^T T_i^T X_i N_i e_{v_i} + \tilde{A}_{v_i}^T B_i^T T_i X_i N_i e_{v_i} \\
- e_{v_i}^T N_i^T X_i T_i \phi_{v_i}^T - (\phi_{v_i})^T T_i^T X_i T_i \phi_{v_i}^T \\
+ \tilde{A}_{v_i}^T B_i^T T_i X_i T_i \phi_{v_i}^T - e_{v_i}^T N_i^T X_i N_i e_{v_i} \\
- e_{v_i}^T j \omega_{fa} X_i T_i \phi_{v_i}^T + e_{v_i}^T j \omega_{fa} X_i T_i \phi_{v_i}^T \\
+ e_{v_i}^T j \omega_{fa} X_i T_i \phi_{v_i}^T \\
= -e_{v_i}^T N_i^T X_i N_i e_{v_i} \\
- e_{v_i}^T j \omega_{fa} X_i T_i \phi_{v_i}^T + e_{v_i}^T j \omega_{fa} X_i T_i \phi_{v_i}^T
$$

(34)
On the other hand, using Lemma 1 and (26), one has

\[
\dot{V}(e_{v_i}) < e_{v_i}^T (N_i^T X_i + X_i N_i + \epsilon_i \theta M_i) e_{v_i}
+ \epsilon_i^{-1} X_i T_i T_i^T X_i e_{v_i} - F_i^T (T_i B_i)^T X_i e_{v_i}
- e_{v_i}^T X_i (T_i B_i) E_i.
\]

Replacing (34) and (35) into (33) gives

\[
\begin{pmatrix}
\Sigma_1^{1} \\
\Sigma_1^{2} \\
\Sigma_1^{3} \\
\end{pmatrix}
\begin{pmatrix}
\Sigma_1^{1} \\
\Sigma_1^{2} \\
\Sigma_1^{3} \\
\end{pmatrix} < 0,
\]

(36)

where

\[
\begin{align*}
\Sigma_1^{1} &= -\omega_i \omega_f \alpha_i X_i - N_i^T X_i N_i - j \omega_f \alpha_i N_i \\
&+ j \omega_f N_i^T X_i \\
&+ N_i^T X_i + X_i N_i + \epsilon_i \theta M_i \\
&- (Z^T \tilde{C}_i)^T W_i^T W_i Z^T \tilde{C}_i, \\
\Sigma_1^{2} &= N_i^T X_i T_i B_i + j \omega_f \alpha_i X_i T_i B_i - X_i T_i B_i, \\
\Sigma_1^{3} &= -N_i^T X_i T_i - j \omega_f \alpha_i X_i T_i + X_i T_i, \\
\Sigma_1^{4} &= -B_i^T T_i^T X_i T_i B_i + \sigma_i^2 I, \\
\Sigma_1^{5} &= B_i^T T_i^T X_i T_i, \\
\Sigma_1^{6} &= -T_i^T X_i T_i - \epsilon_i I.
\end{align*}
\]

It can be re-written as

\[
T_{2i} + V_{2i} S_{2i} + S_{2i}^T V_{2i} - S_{2i}^T X_i S_{2i} < 0,
\]

(37)

with

\[
T_{2i} = \begin{pmatrix}
-\omega_f \omega_f \alpha_i X_i + \epsilon_i \theta M_i & - (Z^T \tilde{C}_i)^T W_i^T W_i Z^T \tilde{C}_i \\
0 & 0 \\
0 & \sigma_i^2 I \\
\end{pmatrix}
\]

\[
S_{2i} = (N_i - T_i B_i T_i), \quad V_{2i} = \begin{pmatrix} X_i - j \omega_f \alpha_i X_i \\
0 \\
0 \end{pmatrix}
\]

Similar to Theorem 1, (37) can be shown to be equivalent to

\[
\begin{pmatrix}
T_{2i} + K_{2i} S_{2i} + S_{2i}^T K_{2i}^T, \\
* \\
\end{pmatrix}
\begin{pmatrix}
- K_{2i} + V_{2i} + S_{2i}^T Y_{2i} \\
- (X_i + V_{2i} + Y_{2i}) \\
\end{pmatrix} < 0,
\]

(38)

for new general matrices \(K_{2i}\) and \(V_{2i}\). Hence, by selecting

\[
K_{2i}^T = (Y_{i}^T Y_{i}^T K_{i}^T 0), \quad V_{2i} = \sigma_2 Y_i,
\]

for a scalar \(\sigma_2\), an arbitrary matrix \(K_i\) and a nonsingular general matrix \(Y_i\), one can obtain the following sufficient condition

\[
\begin{pmatrix}
\Sigma_1^{1} & \Sigma_1^{2} & \Sigma_1^{3} \\
\Sigma_1^{4} & \Sigma_1^{5} & \Sigma_1^{6} \\
\end{pmatrix}
\begin{pmatrix}
Y_i T_i \\
K_i Y_i T_i \\
\end{pmatrix} < 0,
\]

with

\[
\begin{align*}
\Sigma_1^{1} &= Y_i N_i + N_i^T Y_i^T - \omega_f \omega_f \alpha_i X_i + \epsilon_i \theta M_i \\
&- (Z^T \tilde{C}_i)^T W_i^T W_i Z^T \tilde{C}_i, \\
\Sigma_1^{2} &= -Y_i T_i B_i + N_i^T Y_i^T K_i, \\
\Sigma_1^{3} &= -Y_i + X_i - j \omega_f \alpha_i X_i + \sigma_2 N_i^T Y_i^T, \\
\Sigma_1^{4} &= \sigma_i^2 I - K_i Y_i T_i B_i - B_i^T T_i^T Y_i^T K_i, \\
\Sigma_1^{5} &= -K_i Y_i - \sigma_2 B_i^T T_i^T Y_i^T, \\
\Sigma_1^{6} &= -(X_i + \sigma_2 Y_i + \sigma_2 Y_i^T).
\end{align*}
\]

By replacing \(N_i\) and \(T_i\) with their respective values, and applying the linearising change of variables \(U_i = Y_i H_i, R_i = Y_i S_i, (30)\) is obtained. This guarantees residual performance index (17) and the asymptotic stability of error dynamics (9).

\[\square\]

Remark 4 Given that LMIs (30) \(\forall i\) are in the complex domain, most solvers cannot directly handle them. Hence, the following equivalent statements are used for a complex Hermitian matrix \(L(x)\)

\[1.\quad L(x) < 0,\]

\[2.\quad \begin{pmatrix} \text{Re}(L(x)) & \text{Im}(L(x)) \\
-\text{Im}(L(x)) & \text{Re}(L(x)) \end{pmatrix} < 0,\]

where \(\text{Re}(L(x))\) represents the real part of \(L(x)\) and \(\text{Im}(L(x))\) its imaginary part. More details can be found in [46].

Theorem 3 For \(F_i = 0, \bar{F}_i = 0, d_{v_i} \neq 0, \phi_i \neq 0, \) let \(\beta_i, \eta_i, \theta_M, \sigma_{3i}\) and \(\epsilon_i\) be strictly positive scalars, error dynamics (13) is asymptotically stable and performance indexes (19) are guaranteed if \(\forall i \in \{1, \ldots, N\}\), there exist symmetric positive definite matrices \(Q_i, \) matrices \(U_i, R_i\) and unstructured nonsingular matrices \(Y_i\) such that for all possible uncertainties, under imposed constraint (21)

\[
\min_{Q_i, Y_i, U_i, R_i} \beta_i + \eta_i
\]

subject to

\[
\begin{pmatrix}
\Phi_i^1 & \Phi_i^2 & \Phi_i^3 & \Phi_i^4 & \Phi_i^5 \\
\Phi_i^6 & \Phi_i^7 & \Phi_i^8 & \Phi_i^9 & \Phi_i^{10} \\
\Phi_i^{11} & \Phi_i^{12} & \Phi_i^{13} & \Phi_i^{14} & \Phi_i^{15} \\
\end{pmatrix} < 0,
\]

(39)
Proof Let us select the candidate Lyapunov function
\[ J_i = v_i^T P_i v_i + \varepsilon_i \Theta_i \sigma_i(v_i) - R_i Z_i^T C_i^T + \alpha_i \gamma_i, \]
Combining the two yields
\[ \Phi_i = Y_i \tilde{X}_i + U_i Z_i^T C_i \tilde{X}_i - R_i Z_i^T C_i + \tilde{X}_i^T Y_i^T \]
\[ + \varepsilon_i \Theta_i I + (Z_i^T C_i \tilde{X}_i) T_i U_i - (Z_i^T C_i) R_i^T + (Z_i^T C_i)^T W_{ii}^T W_i Z_i^T C_i, \]
\[ \Phi_i^2 = Y_i \tilde{B}_{di} + U_i Z_i^T C_i \tilde{B}_{di} - R_i Z_i^T \tilde{D}_{di} \]
\[ + Z_i^T \tilde{C}_i W_i^T W_i Z_i^T \tilde{D}_{di}, \]
\[ \Phi_i^3 = R_i \tilde{X}_i - \bar{Y}_i \tilde{X}_i \]
\[ - U_i Z_i^T C_i \tilde{X}_i - (Z_i^T C_i)^T W_i^T W_i \tilde{X}_i, \]
\[ \Phi_i^4 = Y_i + Y_i H_i Z_i^T C_i, \]
\[ \Phi_i^5 = -Y_i + \varepsilon_i Q_i + \sigma_3 \tilde{A}_i^T Y_i^T + \sigma_3 (Z_i^T C_i \tilde{A}_i)^T U_i^T \]
\[ - \sigma_3 (Z_i^T C_i)^T R_i^T, \]
\[ \Phi_i^6 = (Z_i^T \tilde{D}_{di}) W_i^T W_i Z_i^T \tilde{D}_{di} - \varepsilon_i I, \]
\[ \Phi_i^7 = -X_i^T W_i^T W_i Z_i^T \tilde{D}_{di}, \]
\[ \Phi_i^8 = \bar{X}_i \tilde{D}_{di}^T (Z_i^T C_i)^T U_i^T - \sigma_3 Z_i^T \tilde{D}_{di} R_i^T, \]
\[ \Phi_i^9 = X_i^T W_i^T W_i \tilde{X}_i - \varepsilon_i I, \]
\[ \Phi_i^{10} = \sigma_3 Z_i^T R_i^T - \sigma_3 X_i^T Y_i^T - \sigma_3 \tilde{X}_i (Z_i^T C_i)^T U_i^T, \]
\[ \Phi_i^{11} = \sigma_3 Y_i^T + \sigma_3 Z_i^T C_i \tilde{A}_i^T U_i^T, \]
\[ \Phi_i^{12} = -\sigma_3 (Y_i + Y_i^T). \]
The observer gains are then computed as in (22).

The above inequality can be expressed as
\[ \begin{pmatrix} \Gamma_{11} & \Gamma_{12} + \gamma_i^d e^T \gamma_i^{dd} \end{pmatrix} < 0, \]
where \[ \Gamma_{11} = (t_i^T Q_i + Q_i I_i + (Z_i^T C_i)^T W_i^T W_i Z_i^T C_i + \varepsilon_i \Theta_i I + \varepsilon_i^{-1} Q_i \Gamma_i T_i Q_i)^T \]
\[ \Gamma_{12} = \chi_i \tilde{B}_{di} - S_i Z_i^T \tilde{D}_{di} (S_i \tilde{X}_i - T_i \tilde{X}_i) \]
\[ \gamma_i^d = (Z_i^T C_i)^T W_i^T W_i Z_i^T \tilde{D}_{di} - (Z_i^T C_i)^T W_i \tilde{X}_i \]
\[ \gamma_i^{dd} = (Z_i^T \tilde{D}_{di})^T W_i^T W_i Z_i^T \tilde{D}_{di} - \varepsilon_i I \]
Similar to Theorem 1, the above is equivalent to
\[ T_{3i} + \gamma_i (S_{3i} + S_{3i}^T T_{3i}) < 0, \]
where
\[ T_{3i} = \begin{pmatrix} (Z_i^T C_i)^T W_i^T W_i Z_i^T C_i + \varepsilon_i \Theta_i I + \varepsilon_i^{-1} Q_i \Gamma_i & \gamma_i^d \gamma_i^{dd} \\ \gamma_i^{dd} & \gamma_i^{dd} \end{pmatrix} \]
\[ S_{3i} = (N_i \gamma_i \tilde{B}_{di} - S_i Z_i^T \tilde{D}_{di} (S_i \tilde{X}_i - T_i \tilde{X}_i) \gamma_i^d \gamma_i^{dd} \]
\[ \gamma_i = \begin{pmatrix} \gamma_i \gamma_i \\ 0 \end{pmatrix} \]
By selecting
\[ K_{3i}^T = (Y_i^T 0 0 0), \quad \gamma_{3i} = \sigma_3 Y_i, \]
for a scalar \( \sigma_3 \) and a nonsingular general matrix \( Y_i \), one can obtain the following sufficient condition
\[ \begin{pmatrix} A_i^1 & A_i^2 & A_i^3 \\ A_i^2 & A_i^3 & A_i^4 \end{pmatrix} < 0, \]
where
where
\[ A_i^1 = Y_i N_i + N_i^T Y_i^T + (Z_i^i \tilde{C}_i)^T W_i T_i Z_i^i \tilde{C}_i + \varepsilon_i \theta M I, \]
\[ A_i^2 = Y_i T_i \tilde{B}_d - Y_i S_i Z_i \tilde{D}_d + Z_i^i \tilde{C}_i W_i T_i W_i \tilde{X}_i, \]
\[ A_i^3 = Y_i S_i \tilde{X}_i - Y_i T_i \tilde{X}_i - (Z_i^i \tilde{C}_i)^T W_i T_i \tilde{X}_i, \]
\[ A_i^4 = -Y_i + Q_i + \sigma_4 N_i^T Y_i^T, \]
\[ A_i^5 = (Z_i^i \tilde{D}_d)^T W_i T_i Z_i^i \tilde{D}_d - \eta_i^2 I, \]
\[ A_i^6 = \sigma_3 \tilde{B}_d^T T_i Y_i^T - \sigma_3 Z_i^i \tilde{D}_d^T S_i^T Y_i^T, \]
\[ A_i^7 = \tilde{X}_i^T W_i T_i \tilde{X}_i - \beta_i^2 I, \]
\[ A_i^8 = \sigma_3 \tilde{X}_i^T S_i^T Y_i^T - \sigma_3 \tilde{X}_i^T T_i Y_i^T. \]
Replacing \( N_i \) and \( T_i \) with their respective values, and applying the linearising change of variables \( U_i = Y_i H_i, \ R_i = Y_i S_i, \) (39) is obtained. This guarantees residual performance index (19) and the asymptotic stability of error dynamics (9).  

**Remark 5** One could note that it is possible to relax constraint (21). Indeed, this equality constraint implies that the span of the rows of \( U_i \) is included in \( \ker(V_{\tilde{v}}) \). Hence, one could turn this into a minimisation of its maximum singular value which could be minimised, i.e., for a scalar \( \vartheta_i > 0 \)

\[
\min_{U_i} \vartheta_i \]

subject to

\[
-\vartheta_i I + U_i V_{\tilde{v}} \vartheta_i^{-1} (U_i V_{\tilde{v}})^T < 0. \tag{44}
\]

Applying the Schur complement to (44) yields the following LMI

\[
\begin{pmatrix}
\vartheta_i I \\ U_i V_{\tilde{v}}
\end{pmatrix}
\begin{pmatrix}
* \\
\vartheta_i I
\end{pmatrix} < 0. \tag{45}
\]

**Remark 6** Note that here, as opposed to what is typically done in literature, we do not impose that \( T_i \tilde{B}_d - S_i Z_i \tilde{D}_d = S_i \tilde{X}_i = 0 \). Indeed, maintaining this constraint while solving the proposed inequalities can be unfeasible for some systems. Contrary to other works using unknown input observer, our approach does not require invertibility conditions except on \( Y_i \) which is inherently required by the proposed LMIs. Thus, no rank condition is required for the existence of the unknown input observer to solve the LMIs.

Residual evaluation

In order to isolate the faulty element (the specific faulty agent and/or faulty link), the residuals are evaluated by comparing them with an offline computed threshold defined hereafter. For this purpose, let us select the following root-mean-square evaluation functions [41], \( \forall p \in N_i \cup i \)

\[
J_{i,p}^e(t) = ||r_i^p(t)||_{\text{rms}}
\]

\[
= \left( \frac{1}{T_w} \int_{t}^{t+T_w} (r_i^p(\tau))^T r_i^p(\tau) d\tau \right)^{\frac{1}{2}}, \tag{46}
\]

where \( T_w \) is a finite evaluation window with

\[
r_i^p(t) = (r_i^1(t))^T, (r_i^2(t))^T, \ldots, (r_i^{|N_i|}(t))^T,
\]

and \( r_i^p(t) \in \mathbb{R}^n, \forall p \in N_i \cup i \). Noise, disturbances, communication uncertainties (etc.) are treated as unstructured unknown inputs, and the RMS threshold is computed as

\[
J_{i,pb}^e = \sup_{\text{attack/fault free}} ||r_i^p(t)||_{\text{rms}}, \tag{47}
\]

where one could set \( J_{i,pb}^e = \max\{J_{i,1}^e, \ldots, J_{i,|N_i|}^e\} \). For isolation purpose, let us define the secure detection flags \( \pi_i \), such that if \( J_{i,p}^e(t) \leq J_{i,pb}^e \) then \( \pi_i = 0 \) and \( \pi_i = 1 \) when \( J_{i,p}^e(t) > J_{i,pb}^e \). An agent \( i \) is assumed to request the secure detection flag of its neighbours when a fault or an attack has been detected through the generated residual functions \( J_{i,j}^e(t), j \in N_i \).

In order to summarise the proposed scheme, two algorithms are proposed hereafter. Optimisation Algorithm 1 is ran offline and proposes steps to compute the observer matrix gains using a finite-frequency mixed \( \mathcal{H}_\infty/\mathcal{H}_- \) approach by simultaneously combining Theorems 1–3 and Remark 5. Define the multi-objective cost function

\[
s_i = \frac{\lambda_{i1}\eta_i + \lambda_{i2}\beta_i + \lambda_{i3}\vartheta_i}{\lambda_{i4}\gamma_i + \lambda_{i5}\delta_i}, \tag{48}
\]

where \( \lambda_{i1}, \lambda_{i2}, \lambda_{i3}, \lambda_{i4}, \lambda_{i5} \) are positive trade-off weighing constants.

**Algorithm 1:** Observer–Detector module parameter computation at agent \( i \) (offline)

1. Construct local model (7)
2. Define \( \Omega_{r_e} \) and choose the multi-objective weights \( \lambda_{i1}, \lambda_{i2}, \lambda_{i3}, \lambda_{i4}, \lambda_{i5} \)
3. Set \( \sigma_{i1}, \sigma_{i2}, \sigma_{i3}, W_i, K_i \) and \( \varepsilon_i \)
4. Minimise \( s_i \) by simultaneously solving Theorems 1–3 and (45) in Remark 5
5. Compute the observer matrix gains \( S_i, H_i, N_i, G_{1i}, G_{2i} \) and \( L_i \) from (22) and \( T_i \) from (10a),
6. Compute thresholds (47).
Remark 7 It should be noted that Algorithm (48) ensures that the best solution with respect to cost function (48) is obtained. This renders the residual functions as sensible as possible to the fault and attack signals while guaranteeing the best possible attenuation performance of the disturbances and communication uncertainties with respect to the residual evaluation functions. It is also worth mentioning that the proposed method introduces additional design variables to the optimisation problem (e.g. matrix variables $Y_i$), and no products between Lyapunov matrices ($P_i$, $Q_i$ or $X_i$) and the observer matrices $N_i$. It allows the use of different Lyapunov matrices for each Theorem, and solving Algorithm 1 with the common design variable $Y_i$ which, unlike Lyapunov matrices, is only required to be nonsingular. This fact, along with the addition of variables $\sigma_1, \sigma_2, \sigma_3$ and matrix $K_l$, allows more degree of freedom and reduces the conservatism of the overall solution.

Algorithm 2 given in the following is run online and summarises the detection and isolation logic where an agent $i$ is said to be faulty if $f_{ao}(t) \neq 0$ and/or $f_{si}(t) \neq 0$.

**Algorithm 2: Decision logic for agent $i$ (online)**

1. Apply evaluation functions (46).
2. If $\exists j \in N_i$ such that $J_{ij}^p(t) > J_{ij}^p$, and $J_{ij}^p(t) \leq J_{ij}^p$ then request $\pi_j$. If $\pi_j \neq 0$ then node $j$ is faulty, else the link $(i, j)$ incident to agent $i$ is faulty.
3. If $J_{ij}^p(t) > J_{ij}^p \forall p \in N_i \cup i$, then agent $i$ is faulty.
   - Request $\pi_j$, $j \in N_i$, if $\pi_j \neq 0$ then agent $j$ is also faulty, else the link $(i, j)$ incident to node $i$ is faulty.
4. If $J_{ij}^p(t) < J_{ij}^p \forall p \in N_i \cup i$, then no fault/attack has occurred.

4 Illustrative example

To show the effectiveness of the proposed algorithm, let us consider a heterogeneous MAS composed of one-link flexible joint manipulator robots. In the following, there are three followers labelled 1 to $N = 3$ and one virtual leader labelled 0. They are connected according to the directed graph topology represented in Fig. 1.

![Communication topology](image)

The associated adjacency matrix is given as

$$A = \begin{pmatrix} 0 & 0.5 & 0.5 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$  

Their dynamics is expressed as [42]

$$\begin{cases} \dot{\theta}_{mi} = \omega_{mi}, \\ \dot{\omega}_{mi} = \frac{J_{mi}}{J_{mi}}(\theta_{li} - \theta_{Mi}) - \frac{B_i}{J_{mi}}\omega_{mi} + \frac{K_t}{J_{mi}}u_i, \\ \dot{\theta}_{li} = \omega_{li}, \\ \dot{\omega}_{li} = -\frac{J_{li}}{J_{li}}(\theta_{li} - \theta_{Mi}) - \frac{m_i g h_i}{J_{li}} \sin(\theta_{li}), \end{cases}$$

where $\theta_{mi}$ is the rotation angle of the motor, $\theta_{li}$ is the rotation angle of the link, $\omega_{mi}$ and $\omega_{li}$ are their angular velocities. The following table summarises the parameters.

| Parameter                        | Unit      |
|----------------------------------|-----------|
| Link inertia $J_l$               | kg m$^2$  |
| Motor inertia $J_{mi}$           | kg m$^2$  |
| Viscous friction coefficient $B_l$ | Nm V$^{-1}$ |
| Amplifier gain $K_t$             | Nm V$^{-1}$ |
| Torsional spring constant $k_l$  | Nm rad$^{-1}$ |
| Link length $l_i$                | m         |
| Mass $m_i$                       | kg        |
| Gravitational acceleration $g$   | ms$^{-1}$ |

By setting, for all $i = 1, 2, 3$, $x_i^T = (\theta_{mi} \omega_{mi} \theta_{li} \omega_{li})$ and $x_0^T = (x_{01} x_{02} x_{03} x_{04})$ where $x_0$ is the virtual leader state, the state space representation can be given as

$$A_i = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -\frac{J_{mi}}{J_{mi}} & -\frac{B_i}{J_{mi}} & \frac{k_i}{J_{mi}} & 0 \\ 0 & 0 & 0 & 1 \\ \frac{k_i}{J_{li}} & 0 & 0 & \frac{k_i}{J_{li}} \end{pmatrix}, \quad B_{ui} = \begin{pmatrix} 0 \\ K_t \\ 0 \\ 0 \end{pmatrix}. $$
\[ B_{d_i} = \begin{pmatrix} 0 & 0.1 & 0 \\ 0.5 & 0 & \end{pmatrix}, \quad \varphi_i(x_i(t)) = \begin{pmatrix} 0 \\ 0 \\ \frac{m_i g b_i}{J_i} \sin(\theta_i) \end{pmatrix}, \]

\[ B_{f_i} = B_{d_i}, \quad D_{f_i} = \frac{1}{1}, \quad D_{f_2} = D_{f_3} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \]

\[ D_{d_1} = \begin{pmatrix} 0.05 \\ 0.1 \end{pmatrix}, \quad D_{d_2} = \begin{pmatrix} 0.1 \\ 0.2 \end{pmatrix}, \quad D_{d_3} = \begin{pmatrix} 0.5 \\ 0.7 \end{pmatrix}, \]

\[ C_1 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad C_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad C_3 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \]

\[ D_{c_{12}} = 1, \quad D_{a_{13}} = 1, \quad D_{z_{31}} = 1, \quad D_{u_{31}} = 1, \quad D_{c_{12}} = 1, \quad D_{u_{12}} = 1, \quad D_{z_{21}} = 1, \quad D_{a_{21}} = 1. \]

In the following simulations, the parameter uncertainties are considered as \( \Delta a_{i_j}(t) = 0.1 \sin(a_{i_j} t) \) and the perturbations \( d(t) \) as Gaussian white noise with values in \([-0.2, 0.2]\). For the followers, the parameters are chosen as \( m_1 = m_2 = m_3 = 0.21kg, k_1 = 0.18Nm \cdot rad^{-1}, k_2 = 0.1Nm \cdot rad^{-1}, k_3 = 0.22Nm \cdot rad^{-1}, B_1 = 4.6 \times 10^{-2}NmV^{-1}, B_2 = 3.6 \times 10^{-2}NmV^{-1}, B_3 = 5.6 \times 10^{-2}NmV^{-1}, J_{m1} = J_{m2} = J_{m3} = 3.7 \times 10^{-3}kgm^2, J_{i1} = J_{i2} = J_{i3} = 9.3 \times 10^{-3}kgm^2, K_{r1} = 0.08NmV^{-1}, K_{r2} = 0.085NmV^{-1}, K_{r3} = 0.09NmV^{-1}, g = 9.8m/s^2, h = 0.3m. \)

The leader parameters are given as \( m_0 = 0.21kg, k_0 = 0.18Nm \cdot rad^{-1}, B_0 = 4.6 \times 10^{-2}NmV^{-1}, J_{m0} = 3.7 \times 10^{-3}kgm^2, J_{i0} = 9.3 \times 10^{-3}kgm^2, K_{r0} = 0.08NmV^{-1}. \)

Remark 8 It should be highlighted that the computation of the matrix gains is done offline and once. Based on Theorems 1–3, for each agent, the observer matrix gains are computed according to Algorithm 1. Therefore, a set of LMIs has to be solved offline and once. One can note that the dimension and number of LMIs linearly increase as the state and number of agents increase. Here, \( 4N \) LMIs \( (N \) is the number of agents \) should be solved. For an agent \( i \), its dimensions are: \((3n_i^x + n_i^f + n_i^e) \times (3n_i^x + n_i^f + n_i^e)\) for Theorem 1, \((3n_i^x + n_i^f + N_i n_f a) \times (3n_i^x + n_i^f + N_i n_f a)\) for Theorem 2, \((3n_i^x + n_i^d + n_i^f + n_i^e) \times (3n_i^x + n_i^d + n_i^f + n_i^e)\) for Theorem 3 and \( n_i^x \times n_i^x \) for Remark 5. These dimensions are given in Table 2 for the illustrative example. Additionally, for each agent, the size of the FDI modules (i.e. \((\text{Eq.} \ (8))\)) is only dependent on the number of neighbouring agents regardless of the agents' control inputs, which makes the proposed scheme highly scalable.

Remark 9 It is interesting to note that for implementation of the method proposed in this work, each agent

\[ M_1 = [1.6207 \ 0.2210 -0.5444 \ 3.2570], \quad M_2 = [1.6924 \ 0.2308 -0.5685 \ 3.4011], \quad M_3 = [1.7642 \ 0.2405 -0.5925 \ 3.5452]. \]

The multi-objective weights are chosen as \( \lambda_{i1} = \lambda_{i2} = \lambda_{i3} = \lambda_{i4} = \lambda_{i5} = 1, \forall i. \) The vector \( \mathcal{E}_j \) is assumed to belong to the finite-frequency domain \([0, 0.1]\). It is worth noting that inequalities (20), (30), (39) and (45) can be solved using an appropriate solver (YALMIP, etc. [48]).

\[ \forall i \in \{1, 2, 3\}, \text{Algorithm 1 is applied for } \sigma_{i1} = 1, \sigma_{21} = 0.2, \sigma_{31} = 0.1, K_i = -2B_{u_i}, \varepsilon_i = 0.04 \text{ and } W_i = I, \text{yielding } \eta_{i1} = 0.2, \beta_1 = 0.2, \theta_1 = 0.01, \gamma_1 = 0.1, \varphi_1 = 0.81, \eta_2 = 0.15, \beta_2 = 0.15, \theta_2 = 0.02, \gamma_2 = 0.1, \varphi_2 = 0.85, \eta_3 = 0.04, \beta_3 = 0.4, \theta_3 = 0.01, \gamma_3 = 0.7, \varphi_3 = 0.77. \]

### Table 2
LMIs dimensions for each agent, where LMIST1: LMI Size in Theorem 1, LMIST2: LMI Size in Theorem 2, LMIST3: LMI Size in Theorem 3, LMIST4: LMI Size in Remark 5

| Agent | LMIST1 | LMIST2 | LMIST3 | LMIST4 |
|-------|--------|--------|--------|--------|
| 1     | 40 \times 40 | 39 \times 39 | 46 \times 46 | 12 \times 12 |
| 2     | 27 \times 27 | 26 \times 26 | 30 \times 30 | 8 \times 8 |
| 3     | 13 \times 13 | 13 \times 13 | 14 \times 14 | 4 \times 4 |
A distributed fault detection scheme

Fig. 4 Residual evaluation functions at agent 2 in scenario 1

Fig. 3 Residual evaluation functions at agent 1 in scenario 1. The dashed red lines represent the threshold

Fig. 5 Residual evaluation functions at agent 3 in scenario 1

The dashed red lines represent the threshold

The dashed red lines represent the threshold

Let us consider hereafter two scenarios. In the first one, two faults occur in the network: a sensor fault $f_{s1}(t)$ at agent 1 and an actuator fault $f_{a3}(t)$ at agent 3, as represented in Fig. 2. Figures 3, 4 and 5 show the generated residual evaluation functions by agents 1, 2 and 3, respectively. The worst case analysis of the evaluation functions corresponding to the non-faulty operation of the network under disturbances and uncertainties leads to the following thresholds $J_{1th}^e = 0.048$, $J_{2th}^e = 0.03$ and $J_{3th}^e = 0.027$ under the evaluation window $T_w = 10s$. It is usually not easy to accurately compute the value of the supremum of the RMS function in (47) to simultaneously prevent false alarms and avoid missed detections. As such, a series of Monte Carlo simulations have been conducted where the supremum of the RMS function in (47) is calculated...
under the healthy operation of the MAS, with different noises, disturbances and uncertainties. The corresponding maximum value has been taken as an appropriate threshold. The sampling period is set as $T_s = 10^{-1}$ s. One could see from Figs. 3, 4 and 5 that the faults could be clearly distinguished. Additionally, according to Algorithm 2, one can see from Fig. 3 that all generated functions $J_{e,1}(t)$, $J_{e,2}(t)$ and $J_{e,3}(t)$ increase at around $t = 20s$ and exceed the defined threshold due to the sensor fault $f_{s_1}(t)$ occurring at agent 1. This confirms that a fault has occurred at agent 1. Figure 4 further confirms this, since only $J_{e,3}(t)$ increases due to this fault. At $t = 40s$, the actuator fault $f_{a_1}(t)$ occurs at agent 3, where one can see in Fig. 3 that agent 1 detects it (its residual evaluation function for agent 3, i.e. $J_{e,3}(t)$, is greater than $J_{e,1}^{th}$ even though both $J_{e,1}(t)$ and $J_{e,2}(t)$ are lower than $J_{e,1}^{th}$). Hence, according to Algorithm 2, agent 1 can distinguish that the fault $f_{s_1}(t)$ has disappeared and that agent 3 is now faulty. This is confirmed for agent 3 in Fig. 5.

Remark 10 It is worth mentioning that the sensor fault matrices $D_{f_2}$ and $D_{f_3}$ are not full column rank. Hence, the methods proposed in [27,28] for instance cannot be applied. Moreover, the effectiveness of the proposed method has been shown for heterogeneous MASs under directed topologies. Besides, compared with the decentralised observer proposed in [49] for example, in which faults occurring at agent $i$ can only be detected

---

Fig. 6 Simulated attack signals in scenario 2, where $f_{z_21}(t) = [f_{z_{21,1}}(t), f_{z_{21,2}}(t)]^T$

Fig. 7 Residual evaluation functions at agent 1 in scenario 2

Fig. 8 Residual evaluation functions at agent 2 in scenario 2

A distributed fault detection scheme

Fig. 10 Control efforts in: a the faultless case, b scenario 1, c scenario 2

Fig. 11 Estimation errors: a at agent 1 in the faultless and attackless case, b at agent 2 in the faultless and attackless case, c at agent 3 in the faultless and attackless case, d at agent 1 in scenario 1, e at agent 2 in scenario 1, f at agent 3 in scenario 1, g at agent 1 in scenario 2, h at agent 2 in scenario 2 and i at agent 3 in scenario 2
by the agent itself, our distributed observer can detect both the agent’s faults and its neighbours’ faults. At last, it can be noticed that the matching condition, i.e. \(\text{rank}(CtBf_t) = n_f\), required in many existing works (e.g. [50]), is not needed in our methodology. Indeed, this condition is not satisfied for agents 2 and 3.

In the second scenario, two types of faults are considered: a data injection attack incident to agent 1 targeting the link going from agent 3 to 1, i.e. \(f_{13}^c(t) = f_{13}^u(t)\) occurring at \(15s \leq t \leq 40s\), and a replay attack incident to agent 2 at the link going from agent 1 to 2 at \(t = 70s\), i.e. \(f_{21}^c(t)\) and \(f_{21}^u(t)\) with a delay of \(T_{12} = 70s\). \(f_{13}^c(t)\), \(f_{13}^u(t)\), \(f_{21}^c(t)\) and \(f_{21}^u(t)\) are represented in Fig. 6. Figures 7, 8 and 9 show the generated evaluation functions by agents 1, 2 and 3, respectively, in the second scenario. The worst case analysis of the evaluation functions corresponding to the attack-less operation of the network under disturbances and uncertainties leads to the following thresholds \(J_{1th}^e = 0.016\), \(J_{2th}^e = 0.0017\), \(J_{3th}^e = 0.02\). It is clear from the evaluation functions that the attacks can be distinguished when surpassing the computed thresholds. Indeed, from Fig. 7, one can see that the data injection attack in the link from 3 to 1 has been detected according to Algorithm 2. It is confirmed that this fault is an edge fault upon requesting agent 3’s detection flag, as \(J_{3,3}^e\) stays below the defined threshold throughout the duration of the attack. From Fig. 8, the replay attack in the link from agent 1 to 2 has been detected by \(J_{2,1}^e(t)\) at \(t = 70s\) which is confirmed by the fact that \(J_{2,1}^e\) does not react to the attack.

The control efforts corresponding to the faultless case and scenarios 1 and 2 are depicted in Fig. 10. Figure 11 shows the estimation errors generated by the FDI modules for agents 1, 2 and 3, respectively. It can clearly be seen that the estimation errors converge to zero in the absence of any fault or attack.

From these simulations, it can be seen that the proposed FDI scheme is able to detect and isolate attacks, actuator faults and sensor faults in the presence of disturbances, noise and communication uncertainties.

5 Conclusion

In this paper, the problem of FDI in Lipschitz nonlinear MASs with disturbances, subject to actuator, sensor and communication faults has been addressed. A multi-objective finite-frequency \(H_-/H_\infty\) design along with nonlinear UIOs has been proposed. Sufficient conditions have been derived in terms of a set of LMIs. The combination of UIOs, removal of strict rank conditions and finite-frequency method has been shown to provide extra degrees of freedom in the FDI filter design. Additionally, the multi-objective method guarantees that the evaluation functions are robust with respect to all admissible disturbances and uncertainties and sensitive to all types of faults. A numerical example has been studied in order to showcase the effectiveness of the proposed scheme. As future works, instead of considering Lipschitz nonlinear systems, one could investigate other classes of nonlinear uncertain systems including chained-form dynamics. Based on the proposed FDI scheme, it would also be possible to design some fault accommodation strategies.

Funding This study was funded by the ANR and Region Hauts-de-France under project I2RM.
