In this work, a micron-sized three-way nitrogen-doped carbon tube covered with MoS$_2$ nanosheets (TNCT@MoS$_2$) was synthesized and applied in photocatalytic water splitting without any sacrificial agents for the first time. The micron-sized three-way nitrogen-doped carbon tube (TNCT) was facilely synthesized by the calcination of commercial sponge. The MoS$_2$ nanosheets were assembled on the carbon tubes by a hydrothermal method. Compared with MoS$_2$, the TNCT@MoS$_2$ heterostructures showed higher H$_2$ evolution rate, which was ascribed to the improved charge separation efficiency and the increased active sites afforded by the TNCT.

Keywords: photocatalysis, MoS$_2$, three-way nitrogen-doped carbon tubes, hydrogen evolution, water splitting

INTRODUCTION

Photocatalytic water splitting is one of the promising strategies to address the global energy and environmental problems (Hinnemann et al., 2005; Dong et al., 2013; Jiang et al., 2013; Chang et al., 2014; Pan et al., 2016; Wang et al., 2016; Anna et al., 2018; Chen et al., 2018; Zeng et al., 2018). TiO$_2$ is the most investigated material in the semiconductor photocatalysis research field. However, due to the wide bandgap, it is only responsive to UV light, which greatly limits its photocatalytic efficiency (Cui et al., 2013; Shi et al., 2018). In recent years, many visible-light-driven semiconductors have been designed and applied in solar energy conversion research fields (Wang et al., 2014; Pan, 2016; Shao et al., 2017, 2018; Cheng et al., 2018, 2019; Marchal et al., 2018; Wolff et al., 2018; Yang et al., 2019). Molybdenum disulfide (MoS$_2$) is one of the most attractive materials. As a graphene-like hexagonal material with close-packed layered structure, MoS$_2$ has a sandwich architecture, in which the strong covalent bonds among S-Mo-S atoms lies in the layer while the weak van der Waals force exists between the layers (Cheiwchanchamnangij and Lambrecht, 2012). With the variable atomic coordination and the electronic structure, MoS$_2$ exhibits extremely fast carriers mobility (over 200 cm$^2$·V$^{-1}$·s$^{-1}$). Furthermore, the band gap is adjustable from 1.19 to 1.80 eV through the variation of layer thickness, nanometer size and ion doping. Hence, MoS$_2$ is an excellent light absorbing material and has high utilization of sunlight. Additionally, the nano-scale molybdenum disulfide has a complicated edge structure with high unsaturation and high reactivity (Wang et al., 2018). MoS$_2$ has optimal band gap, high reactive spots and fast mobility of charge carriers, which is beneficial for the photocatalysis. However, the photocatalytic efficiency of pure MoS$_2$ is still limited by the fast recombination of photogenerated carriers. The construction...
of heterostructure of nano-sized MoS$_2$ coupled with other semiconductor or carbon materials has attracted great interest (Xiang et al., 2012; Jia et al., 2013; Guo et al., 2015; Lang et al., 2015; Pan et al., 2016). It was proposed that the hybrids could provide appropriate band structure for water splitting and improve the separation efficiency of photogenerated carriers.

Herein, MoS$_2$ nanosheets assembled on a micron-sized three-way nitrogen-doped carbon tube (TNCT@MoS$_2$) was synthesized and applied in the photocatalytic water splitting for the first time. As illustrated in Scheme 1, the micron-sized three-way nitrogen-doped carbon tube (TNCT) was first prepared by a calcination method. Then, the MoS$_2$ nanosheets were loaded on the TNCT by a hydrothermal method. The as-prepared TNCT@MoS$_2$ composite exhibits much higher photocatalytic activities than pure MoS$_2$, which is ascribed to the improved charge separation and transfer efficiency afforded by the TNCT.

**EXPERIMENTAL SECTION**

**Materials**

Ammonium molybdate tetrahydrate, thiourea, ethanol, and terephthalic acid (TA) were supplied by China National Pharmaceutical Group Chemical Testing Co., Ltd. Melamine sponge is purchased from Zhengzhou Fengtai nanomaterial Co., Ltd. The water used in the experiment is secondary deionized water.

**Preparation of TNCT**

The commercial melamine sponge was calcined at 450°C for 3 h in vacuum, and the sponge changed from white to black. At this time, the required three-way nitrogen-doped carbon tube (TNCT) was initially formed.

**Fabrication of TNCT@MoS$_2$**

First, 1.24 g ammonium molybdate tetrahydrate, 2.26 g thiourea and 35 ml deionized water was mixed and stirred at room temperature for 20 min. Then, the mixture and the as-prepared black TNCT were transferred to a 100 mL polytetrafluoroethylene reactor. The reactor was heated in an oven at 220°C for 24 h. After the reaction, the supernatant is poured off, and the sponge block is clamped out. After being mashed, the sponge block was centrifuged and washed with distilled water and ethanol for several times. Then, it was dried in a vacuum drying box at 60°C for 12 h, and a black powder was obtained. Finally, the black powder was calcined at 800°C in N$_2$ atmosphere for 4 h.

**Instruments**

Scanning Electron Microscope (SEM) equipped with a field-emission gun operated at 5.0 kV was used to characterize the morphology of the as-obtained product. High-Resolution Transmission Electron Microscopy (HRTEM) was taken on JEM-2100F instrument at an accelerating voltage of 200 kV. X-ray diffraction (XRD) analyses carried out on a Bruker D8 Advance Diffractmeter with Cu Kα radiation (1.5418 Å). X-ray photoelectron spectroscopy (XPS) was carried on Thermo Scientific Escalab 250Xi with Al Kα as the excitation source. Photoelectrochemical performance measurements were performed in a standard three-electrode PEC cell, with three-way nitrogen-doped carbon tube@MoS$_2$, saturated calomel electrode, and Pt wire as the working electrode, reference electrode, and counter electrode, respectively. The fluorescence spectrum was carried out with an Edinburgh FLS920 spectrofluorimeter (Edinburgh Instruments Ltd, England) equipped with a xenon lamp. Raman spectra were measured by LabRAM HR800 confocal microscope Raman spectrometer from Horiba Jobin-Yvon, France. The UV/Vis diffuse reflection spectra (DRS) were taken on a Shimadzu UV-2550 spectrophotometer with an integrated sphere attachment and BaSO$_4$ used as the reference sample.

**Photocatalytic Activity for Water Splitting**

In a typical process, 20 mg of the as-prepared photocatalysts and 10 mL aqueous solution in a 20 mL Quartz bottle sealed with silicone rubber septum. Prior to photocatalysis experiment, the sample solutions were thoroughly deaerated by evacuation and purged with nitrogen for 10 min. Then it was irradiated.
by a 1,000 W Xenon lamp (the light intensity irradiating the photocatalysts was 0.17 W) at room temperature under constant stirring. The produced gas was analyzed by gas chromatography (FULI 9750, TCD, Nitrogen as the carrier gas, and 5 Å molecular sieve column).

Because there was no O₂ detected in this photocatalytic water splitting system, to confirm the photocatalytic water splitting process, the intermediate OH directly photogenerated from water was determined as following (Yang et al., 2009). A fluorescence probe named terephthalic acid (TA) was...
added into the above-mentioned photocatalytic H\textsubscript{2} evolution measurement system to capture OH photogenerated from water, in a result of producing TAOH. Typically, 0.01M TA, 20 mg TNCT@MoS\textsubscript{2}, and 10 mL water were mixed in a 20 mL Pyrex bottle at ambient temperature and atmospheric pressure, sealed with silicone rubber septum. The sample solutions were thoroughly deaerated by evacuation and argon bubbling for 2 h prior to photocatalysis experiment. Then it was irradiated by a 1,000-W Xe lamp under ambient conditions and magnetic stirring for certain time. The produced solutions containing TAOH were analyzed by fluorescence spectra.

RESULTS AND DISCUSSION

As shown in Figures 1a,b, most of these nitrogen-doped carbon tubes have three-way branches, each of which is about 20 microns in length and 3 micron in diameter. The EDS-mapping pictures show that the doped nitrogen elements are uniformly dispersed in the carbon tubes (Figures 1c,d). The SEM image of TNCT@MoS\textsubscript{2} heterostructures is shown in Figures 1e-h. It can be seen that the MoS\textsubscript{2} nanosheets layer with thickness of 500 nm are uniformly coated on the TNCTs. The MoS\textsubscript{2} nanosheets are interconnected with each other, forming the 2D nanosheets networks. Additionally, the EDS mapping pictures show that
MoS$_2$ nanosheets are uniformly dispersed on the surface of TNCT (Figures 1j,k). XRD peaks of TNCT@MoS$_2$ localized at 20 values of 13.8, 33.5, 39.8, and 58.8° are ascribed to MoS$_2$ with typical hexagonal phase (JCPDS:00-037-1492, Figure 2a). The (002) crystal plane diffraction peak is stronger than the diffraction peaks on other crystal planes, indicating that MoS$_2$ has a good layered packing structure (Zong et al., 2008). An obvious reflection located at 20 = 26.5° is ascribed to the TNCT (002) crystal plane (Figure 2a; Tang et al., 2015). The heterogeneous lattice interfaces of MoS$_2$ and TNCT were clearly observed on the HRTEM images (Figures 2b,d). The lattice fringe spacing of 0.65 nm is ascribed to hexagonal phase MoS$_2$ (Choi et al., 2017). The lattice fringes of TNCT are not significant maybe due to the doping of nitrogen atoms, a dimly visible lattice spacing of 0.22 nm was ascribed to the (100) facet of graphite (Baker and Baker, 2010). The strong wide peaks located at 1,379 cm$^{-1}$ (D-band) in the Raman spectra showed that the presence and partial graphitization of carbon (Supplementary Figure 1; Matthews et al., 1999) in agreement with the results observed from the HRTEM images.

The chemical state of surface species of the samples was further determined by X-ray photoelectron spectroscopy (XPS).

The survey XPS spectra showed that Mo, S, N, C, and O elements existed in the surface layer of the as-papered nanostructures (Supplementary Figure 2). Two peaks located at 228.62 and 231.79 eV are attributed to Mo 3d5/2 and Mo 3d3/2, respectively (Figure 3B; Wang et al., 2017). The peak located at 161.8 eV corresponds to the S 2p3/2 and another one located at 162.7 eV was assigned to S 2p1/2 (Figure 3C; Hu et al., 2014). Three peaks were observed in the C 1s binding region peaks centered at 284.2, 285.4 and 289.2 eV, which were ascribed to graphite-C, -C=C=O and -C*=O groups, respectively (Figure 3D; Christie et al., 1983; Beamson and Briggs, 1993; Witek et al., 1996). Two peaks were observed in the N1s binding region peaks (Figure 3A). The peak centered at 394.5 eV indicated that the doped nitrogen in TNCT was connected with the carbon frame by -N*=N*-C bond (Kudo et al., 1986). It is worth noting that another peak for N1s centered at 396.8 eV was ascribed to Mo(-N*=N-2-C) (George and Kwarcinski, 1995), which indicated that the MoS$_2$ could closely bond with TNCT by the surface -N=C=O group.

The UV-Vis-IR absorbance spectrum shows that TNCT@MoS$_2$ exhibits higher and broader spectral absorption including IR light than that of TNCT and MoS$_2$ (Figure 4A). As shown in Figure 4B, TNCT@MoS$_2$ obviously shows higher photocurrent density than that of MoS$_2$. It indicates that TNCT@MoS$_2$ maybe has better photocatalytic activity.

The photocatalytic activity of the as-prepared catalyst was investigated for the photocatalytic water splitting process without addition of any sacrificial agents, which was performed by a 1,000 W xenon lamp source. It was found that the catalyst showed almost the same photocatalytic activity in the wide pH range of 5-11 and pure water (Figure 5A). The optimal hydrogen production rate of TNCT@MoS$_2$ was 120 µmol/g·h, which is about 9 times faster than that of pure MoS$_2$ (Figure 5B).

For a typical photocatalytic water splitting process, both H$_2$ and O$_2$ are usually produced from water. However, in this work, whereas this system readily produces hydrogen under illumination, the simultaneous liberation of oxygen is not observed. This phenomenon has been observed in much water splitting systems (Duonghong and Grätzel, 1984; Liu et al., 2012; Zhang et al., 2014). It is because the produced O$_2$ or intermediate oxygen species such as OH are readily absorbed by the metal elements such as Mo and W to form steady peroxide complexes,
in a result of inhibiting the release of O$_2$ (Cui et al., 2015). Herein, although there was no O$_2$ determined in this photocatalytic water splitting system, intermediate OH directly photogenerated from water was detected by the fluorescence probe TA (Yang et al., 2009). The fluorescence spectra of TAOH, which is produced through the oxidation of TA by OH, exhibited a peak at 426 nm, indicating the presence of OH (Supplementary Figure 3).

Although the surface of molybdenum sulfide suffer from the reaction runs (Figure 2a) and maintain the same photoactivity for five photocatalytic runs (Supplementary Figure 4), the XRD (Figure 2a) and Raman spectroscopy (Supplementary Figure 4) showed that the crystal structure of the material did not change fundamentally and maintain the same photoactivity for five photocatalytic reaction runs (Figure 5C).

The excellent photocatalytic performance of TNCT@MoS$_2$ is ascribed to the effective separation and transfer of photogenerated carriers. Herein, it was verified by the photoluminescence spectroscopy and photoelectrochemical performance measurements. The photoluminescence (PL) of semiconductors was caused by recombination of photoinduced electrons and holes. If the recombination was suppressed, the PL emission of semiconductors would be quenched. As shown in Supplementary Figure 5, after being combined with TNCT, the PL intensity of MoS$_2$ emission peak obviously quenched. It indicated that the photoinduced charge separation efficiency of TNCT@MoS$_2$ would improve. The photogenerated carriers’ transfer capacity of the as prepared materials was confirmed by electrochemical impedance tests. As shown in Figure 6, TNCT, MoS$_2$, and TNCT@MoS$_2$ all showed classical semicircular Nyquist diagram. The arc radius of TNCT@MoS$_2$ was obviously smaller than that of TNCT and MoS$_2$, which indicated that the photogenerated charges in TNCT@MoS$_2$ would suffer less resistance. It is ascribed to the fast charge transfer from MoS$_2$ nanosheets to carbon tube under full-light irradiation. The formed Mo(-N$_2^+$) =N-$_2$-C bonding connection between MoS$_2$ and TNCT maybe acts as carrier transfer bridge (Figure 3D), which will improve the photogenerated carriers separation and transfer efficiency of TNCT@MoS$_2$. The detailed mechanism and remained questions would be studied in our future work.

CONCLUSIONS

In summary, a micron-sized three-way nitrogen-doped carbon tube covered with MoS$_2$ nanosheets was synthesized and applied in the photocatalytic water splitting without any sacrificial agents for the first time. The micron-sized three-way nitrogen-doped carbon tube is facilely synthesized by the calcination of sponge at 450°C in vacuum. And then the MoS$_2$ nanosheets are deposited on the three-way nitrogen-doped carbon tubes by a simple hydrothermal method. Compared with MoS$_2$, the TNCT@MoS$_2$ heterostructures showed higher H$_2$ evolution rate, which may be ascribed to the improved charge separation and transfer efficiency caused by the three-way nitrogen-doped carbon tube. This work may provide a new design idea for the design of low-cost and efficient photocatalysts.
