Abstract: Even the simplest version of the distribution networks face challenges such as maintaining load voltage and system frequency stability and at the same time minimizing the circulating reactive power in grid-forming nodes. As the consumers at the far end of the radial distribution network face serious voltage fluctuations and deviations once the load varies. Therefore, this paper presents an enhanced distributed control strategy to restore the load voltage magnitude and to realize power-sharing proportionally in islanded microgrids. This proposed study considers the voltage regulation at the load node as opposed to the inverter terminal. At the same time, a supervisory control layer is put on to observe and correct the load voltage and system frequency deviations. This presented method is aimed at replacing paralleled inverter control methods hitherto used. Stability analysis using system-wide methodical small-signal models, the MATLAB/Simulink, and experimental results obtained with conventional and proposed control schemes verify the effectiveness of the proposed methodology.

Keywords: microgrid control; distributed control system; distribution network; voltage regulation; power sharing; smart grid

1. Introduction

A reliable and stable distribution network represents a crucial aspect to successful power distribution to load demands. Suppling electrical power to loads can be enhanced using a well-organized distribution system [1,2]. Radial distribution networks (RDNs) are considered the most frequently employed distributed network [2,3]. RDNs are chains of conducting lines, which are divided into smaller branches for power delivery to customer’s premises. RDNs are more convenient than other configuration, as it is only fed at one end with low initial network cost. Moreover, it has easy circuit protection schemes to coordinate and design owing to its simplicity in establishing system component rating requirements [4]. As per the power network configuration, RDNs can be divided into three categories, i.e., “AC and DC networks”, “single-phase and three-phase networks”, and “balanced and unbalanced networks” [5]. Most of the developing countries use the AC distribution network as opposed to the DC network. Using DC distribution is a new technology, which requires fewer conductors for power dispersal, which reduces the line losses and cost of the conductors [6]. On the other side, the AC system could be either a single-phase or three-phase system [7]. A three-phase AC network can be further be classified as a balanced or unbalanced system: a balanced network contains the positive
phase sequence components with equal magnitude and phase shift, while the unbalanced network has either a positive or negative sequence with irregular magnitude and phase shift. Unequal loading, fault, single-phasing, outages, etc., are considered as the main causes of disturbances in the distribution system voltages and currents [8,9].

The conventional or renewable source of energy-based distributed generations (DGs) is the low-scale power generation network of wattage between a few kW to MW [10]. Power is provided in the system with respect to the power rating of DG and the identification of critical nodes. Over-voltage and over-current may occur without estimation of location and size of DG. DGs can be classified into four types, i.e., (1) injecting real and reactive power; (2) injecting real power and absorbing reactive power; (3) injecting real power solely; and (4) injecting only reactive power [10,11]. Microgrid (MG) is a cluster of different power sources, e.g., distributed generation units, storage units, microturbines, fuel cells, loads, etc. MG is suitable for the low voltage distribution side [12,13]. The primary task of MG is to deliver quality power without being suffered from voltage fall. The penetration of renewable sources such as fuel cells, PV cells into MG has reduced the fuel cost and CO₂ emission [14]. However, proper integration of such sources required the DC to AC inversion, where the setting of power converters and power flow control faces vital challenges. The suitable energy storage system with its control algorithm makes the power flow more efficient [14,15].

Participation of generating units into the grids defines the amount of power to be supplied [2]. The generating unit could also contribute from the distribution side as well. The mode of generation is basically based on the main and subsequent generating units available as a source of power [3,16]. It can be characterized as the centralized generation, where the power generation is controlled by the main power plants and grid. Moreover, depending on the controlling scheme of MG, it can be classified as central controlled MG and local controlled MG, where combination and lone generating units are controlled [11,15]. Depending on the power supply from the substation side, MG operation can be redefined as grid-dependent, where the MG exists in the network even when the main supply is provided from the substation [13]. MG puts its contribution in a grid-dependent radial distribution system when load demand exceeds and power quality goes down. Grid-independent or islanded, where the MG is the only source of power and network is free from the substation that can be occurred during outages. Mainly, MG gives the power during the excess demand in grid-dependent systems, minimizes loss, and maintains power quality [17,18]. It acts as a backup power source during the islanded mode of operation or grid failure situation, controls the loads, converts DC power into AC power, and promises security and protection [19,20].

The study on control of grid-forming units was first carried out in uninterruptible power supply systems with parallel operation [21–23]. In islanded MGs, the droop control schemes widely employ to obtain power sharing by using communication channels. Power-sharing control schemes of DG units based on communication are, master/slave [24–26], concentrated control [25,27,28] and distributed control [29]. Oppositely the control methodologies without using the communication channel are mainly on the droop idea, which includes four leading categories: (1) virtual framework structure-based scheme [30–35]; (2) signal injection strategy [36]; (3) conventional and variants of the droop control [37–43] and (4) “construct and compensate”-based schemes [37,39,44]. Integrated control schemes refer to hierarchical structures consists of primary, secondary, and tertiary control [45]. The work of primary control layers is to maintain the system voltage and frequency and offer the plug-and-play capability of DGs in MG. The secondary control layers use to correct the voltage and system deviations in order to improve the power quality, while the tertiary control employs to interact with the main grid [46].

In this paper, an effort has been made to enhance voltage regulation in radial feeders, usually employed in an islanded MG distribution network. The electric power generated from various DG units is not used efficiently by the end-users in the world as the consumers at the far end of the distributor face serious voltage fluctuations and deviations once the
load varies. In this study, the two DG units are connected to MG through interfacing power inverters. Droop control scheme of parallel-connected inverters is employed at consumers end as opposed to inverter terminal. In islanded mode, the inverter droop control should regulate the user voltage, system frequency, and share-power proportionally. Further, the major contributions of this work are listed below,

- An enhanced distributed control scheme is presented, which can be used for a limited number of grid-forming nodes;
- A distributed secondary control layer is employed to restore the load voltage and frequency deviations. Modeling and analysis of an autonomous operation of inverter-based MG being verified through stability analysis using system-wide mathematical small-signal models;
- MATLAB/Simulink and experimental results are discussed with a comparison of conventional control schemes under load disturbances.

The remainder of this paper is organized as follows. Section 2 presents the operation principle of the system used in this proposed study. Section 3 outlines the derivations of the small-signal model for this MGs system with the employed controls. Section 4 elaborates the stability analysis of the system under the discussed controls. Further, it also presents the simulation and experimental results in detail with a comparison of the conventional and proposed control scheme, and Section 5 concludes the paper.

### 2. Proposed Control Strategy

This section presents the MG setup used in this proposed study. To adequately describe the proposed control scheme, we systematically go about describing the mathematical model and power flow control along with the necessary mathematical representations.

#### 2.1. Microgrid Power Network Model

A radial distribution network with a three-phase, three-wire configuration is used in this study, as shown in Figure 1. Power converters and $RL$ load are connected through feeder 1 and feeder 2. This network can work autonomously in an “islanded” mode. Tables 1 and 2 express the rated system parameters for stability analysis, simulation, and experimental prototype. In this study, load voltage magnitude restoration is considered unlikely the voltage regulation at the inverter terminal. By using the reference frame transformation, the load voltage is transformed into $d$-$q$ axis components. Based on such sensed measurements at $ith$ node of each inverter, the apparent power $S$ is calculated and dispatched to droop controllers of every $ith$ inverter via low-pass filters. Depending on the received information, the droop controllers further send the reference voltage command to inner voltage and current layers. Distributed secondary layer periodically corrects the load voltage and system frequency deviations.

### Table 1. System parameters for stability analysis and experimental prototype.

| Sr. No. | Control Parameters for Stability Analysis | Min | Max |
|---------|------------------------------------------|-----|-----|
| 1       | Droop Gains                               | 0.02| 0.32|
| 2       | Consensus frequency                       | 0.45| -   |
|         | $k_{pf}$                                  | $4.5 \times 10^{-4}$ | - |
| 3       | Consensus voltage                         | 0.3 | 2.5 |
|         | $k_{pV}$                                  | 0.08| 0.48|
|         | $k_{IV}$                                  | $6 \times 10^{-3}$ | - |
| 4       | Time delay                                | 0   | -   |
Table 1. Cont.

| Sr. No. | Control Parameters for Experimental Prototype | Components | Units | Components | Units |
|---------|---------------------------------------------|------------|-------|------------|-------|
| 1       | Operating frequency                         | 50 Hz      |       | Sampling rate | 1 ms |
| 2       | DG units ratings                            | 3 A, 30 V  |       | jX$_{11}$, jX$_{22}$ | 200 uH |
| 3       | $jX_{11}, jX_{22}$                          | 20 uF      |       | $jX_{11}, jX_{22}$ | 60 uH |
| 4       | $L_{\text{line}1}/R_{\text{line}1}$         | 2 mH/0.2 Ω|       | $L_{\text{load}/R_{\text{load}}}$ | 2 mH/10 Ω |
| 5       | $L_{\text{line}2}/R_{\text{line}2}$         | 2 mH/0.2 Ω|       | $L_{\text{d1}/R_{\text{d1}}}$ | 1 mH/5 Ω |

Table 2. System parameters for simulations.

| Sr. | Components | Units | Components | Units |
|-----|------------|-------|------------|-------|
| 1   | Nominal frequency | 50 Hz | $L_{\text{load}/R_{\text{load}}}$ | 80 mH/60 Ω |
| 2   | Simulations $V_{\text{ref}}$ | 300 V | $L_{\text{d1}/R_{\text{d1}}}$ | 10 mH/20 Ω |
| 3   | $L_{\text{line}1}/R_{\text{line}1}$, $L_{\text{line}2}/R_{\text{line}2}$ | 2 mH/0.2 Ω, 2 mH/0.2 Ω | Switching Frequency | 16 kHz |

Figure 1. MG power network model and proposed control strategy.

2.2. Mathematical Model

To understand the varying power relationship corresponding to change in amplitude and frequency, the complex power delivered to the $ith$ ac bus is expressed in term of
network voltages and admittances. The complex power delivered to the \( i \)th bus can be expressed as:

\[
S_i = V_i I_i^* 
\]

(1)

Applying the algebraic multiplication to Equation (A6) shown by Appendix A and then collecting the real part \( P_i \) and imaginary part \( Q_i \) results:

\[
P_i = \sum_{j=1}^{N} |V_i||V_j| \angle (G_{ij} \cos(\varphi_i - \varphi_j) + B_{ij} \sin(\varphi_i - \varphi_j))
\]

(2)

\[
Q_i = \sum_{j=1}^{N} |V_i||V_j| \angle (G_{ij} \sin(\varphi_i - \varphi_j) - B_{ij} \cos(\varphi_i - \varphi_j))
\]

(3)

Power angle \( \varphi \) in medium-voltage lines are small, assuming \( \sin \varphi = \varphi \) and \( \cos \varphi = 1 \), the Equations (2) and (3) re-expressed:

\[
P_{i,R_s=0} \approx \frac{V_i V_j}{X_i} \left[ \sin \varphi_j \right]
\]

(4)

\[
Q_{i,R_s=0} \approx \frac{V_i^2 - V_i V_j \cos \varphi_j}{X_i}
\]

(5)

where the mathematical expression of term \( \varphi_j \) and \( (V_i - V_j) \) is given in Appendix B. Equations (4) and (5) illustrates a direct relationship among the real power \( P_i \) and power angle \( \varphi \) as well as between the reactive power \( Q_i \) and voltage difference \( V_i - V_j \).

2.3. Power Flow Control

DC power source is connected with the \( i \)th inverter bridge, and its output voltage and frequency are adjusted by the power controller and inner voltage and current controllers. All the operating DG units within the system are individually formulated in their \( d-q \) frame, which is based on their angular frequency \( \omega_i \) and angle \( \varphi_i \). Power electronics inverter interfaced among each DG unit and grid are converted to the \( d-q \) frame by using transformation equation as follows:

\[
\begin{bmatrix}
  f_D \\
  f_Q
\end{bmatrix} =
\begin{bmatrix}
  \cos(\varphi_i) & -\sin(\varphi_i) \\
  \sin(\varphi_i) & \cos(\varphi_i)
\end{bmatrix}
\begin{bmatrix}
  f_d \\
  f_q
\end{bmatrix}
\]

(6)

The angle of \( i \)th DG unit’s \( d-q \) fame can be written:

\[
\varphi_i = \int (\xi \omega_i) dt
\]

(7)

Droop control-based power controller block is shown in Figure 2a. Its purpose is to dispatch the voltage reference \( v_{odi}^* \) and \( v_{oij}^* \) to inner control layers. Average output powers \( (P_i, Q_i) \) are obtained from instantaneous power passing low-pass filters, where the instantaneous real \( P \) and reactive \( Q \) power in the \( d-q \) rotating frame can be written as \( p_i = v_{odi} l_{odi} + v_{oij} l_{oij} \) and \( q_i = v_{odi} l_{odi} + v_{oij} l_{oij} \). On individual frame \( d-q \), \( v_{odi}, v_{oij} \) and \( l_{odi}, l_{oij} \) are the load voltage and line current of an \( i \)th inverter. Droop strategy demonstrates the relationship among the active power and system frequency \( p = \omega \), and between the reactive power and feeder load node voltage magnitude \( Q-V \), can be illustrated as, \( \omega_i = \omega_{ref} - m_P P_i \) and \( v_{odi} = V_{ref} - n_Q Q_i \), where \( \omega_{ref}, V_{ref}, m_P \) and \( n_Q \) are nominal frequency, voltage and droop coefficients, respectively, of each \( i \)th DG unit. Further, the reference voltage to the inner voltage layer is denoted by \( v_{odi}^* \). Q-V droop control strategy by considering the load node voltage magnitude can be written by (8), illustrated in Figure 2a.

\[
v_{odi}^* = V_{ref} - n_Q Q_i
\]

(8)
where $V_{\text{ref}}$ is the nominal voltage of all inverters, while $v_{odi}^*$ is responsible for restoring the feeder load node load voltage, which regulates the voltage deviation caused by the droop controllers.

![Figure 2. (a) Power controller of $i$th inverter (b) inner voltage and current control layer.](image)

2.4. Distributed Secondary Control Layer: Voltage and Frequency Regulation

Distributed secondary control layers are used to restores the voltage and frequency deviations as the strategy expressed by Equations (9) and (10).

\[
\omega_{\text{avg}} = \frac{1}{N} \sum_{i=1}^{N} \omega_{DGi} \\
\omega_i = \left(\omega_{\text{ref}} - \omega_{\text{avg}}\right) \\
\varsigma \omega_i = k_p f \omega_i + k_i f \int \omega_i dt
\]  

(9)

where the $\omega_{\text{ref}}$ is the reference frequency, $\omega_{DGi}$ is the measured system frequency that is being sensed at all the nodes of $i$th inverters. The frequency correction term $\varsigma \omega_i$ is sent to the frequency reference of each $i$th inverter shown in Figure 1. $K_p$ and $K_i$ are the proportional and integral gains for controllers.

Load voltage regulations schemes can be expressed as:

\[
V_{\text{avg}} = \frac{1}{N} \sum_{i=1}^{N} V_{DGi} \\
V_i = \left(V_{\text{ref}} - V_{\text{avg}}\right) \\
\varsigma V_i = k_p f V_i + k_i f \int V_i dt
\]  

(10)

where $V_{\text{ref}}$ and $V_{DGi}$ are the nominal reference voltage and measured system voltage, respectively, in d-axis, which is sensed at each inverter’s nodes. $K_p$ and $K_i$ are the proportional and integral gains for controllers. The updated voltage correction $\varsigma \omega$ term is applied to the voltage reference of each $i$th inverter.

3. Small-Signal Analysis of the Microgrid System

Intermittent latencies and delay of component communication links may result in power imbalances between generation sources, deviations in node voltages, and system frequency. Therefore, the stability of the system is analyzed by variations in $P$-$f$ droop gain $m_p$ and communication delay $T_d$. The small-signal modeling strategy is based on three important sub-modules, which are the inverter, network, and loads. State equations of the network and the connected loads with any $i$th DG inverter are presented in the reference frame by using the transformation strategy.
3.1. Primary Controller

From measured output current and voltage, the instantaneous power can be written as \( p = v_{odi}i_{odi} + v_{oq_i}i_{oq_i} \) and \( q = v_{odi}i_{odi} + v_{oq_i}i_{oq_i} \). The small signal modeled for active power can be obtained as given in (11) by linearization.

\[
\Delta P_i = -\omega_{ci}\Delta P_i + \omega_{ci}(i_{odi}\Delta v_{odi} + i_{oq_i}\Delta v_{oq_i} + V_{odi}\Delta i_{odi} + V_{oq_i}\Delta i_{oq_i})
\]

\[
v_{odi} = \begin{bmatrix} v_{odi} & v_{oq_i} \end{bmatrix}^T, \quad i_{odi} = \begin{bmatrix} i_{odi} & i_{oq_i} \end{bmatrix}^T
\]

Algebraic modeling for the voltage controller and the current controller can be expressed as follows,

\[
i^{*}_{odi} = F_i v_{odi} - \omega_b C_{fi}\Delta v_{oq_i} + K_{PVI}(v^{*}_{odi} - v^{*}_{odi}) + K_{IVI}\psi_{di}
\]

\[
i^{*}_{oq_i} = F_i v_{oq_i} + \omega_b C_{fi}\Delta v_{odi} + K_{PVI}(v^{*}_{oq_i} - v^{*}_{odi}) + K_{IVI}\psi_{qi}
\]

\[
v^{*}_{odi} = -\omega_b L_{fi}i_{odi} + K_{PCI}(i^{*}_{odi} - i_{odi}) + K_{PCL}\omega_{di}
\]

\[
v^{*}_{oq_i} = \omega_b L_{fi} + K_{PCI}(i^{*}_{oq_i} - i_{oq_i}) + K_{PCL}\Delta\omega_{qi}
\]

The small signal modeled for active power and current loop is given in Appendix D.

3.2. Grid Side Filter Model

The small signal model of LC output filter and coupling inductance by assuming that voltage provided by the inverter is the same as demand voltage is expressed as in (17)–(19).

\[
\frac{d\Delta i_{odi}}{dt} = -\frac{R_{fi}}{L_{fi}}\Delta i_{odi} + \omega_{ci}\Delta i_{odi} + \frac{1}{L_{fi}}i^{*}_{odi} - \frac{1}{L_{fi}}v_{odi}
\]

\[
\frac{d\Delta v_{odi}}{dt} = \omega_{ci}\Delta v_{odi} + \frac{1}{C_{fi}}i^{*}_{odi} - \frac{1}{C_{fi}}\Delta i_{odi}
\]

\[
\frac{d\Delta i_{oq_i}}{dt} = -\frac{R_{ci}}{L_{ci}}\Delta i_{oq_i} + \omega_{ci}\Delta i_{oq_i} + \frac{1}{L_{ci}}i^{*}_{oq_i} - \frac{1}{L_{ci}}\Delta v_{oq_i}
\]

The LC filter and coupling inductance, their linearization small-signal equations are represented by Appendix E.

3.3. Complete Model of an ith Inverter

The output variables need to the converter in a common reference frame to connect at ith inverter with the rest of the system. In our case, the output currents are the output variables of ith inverters, which can be expressed in vector form \( \Delta i_{odi}, \Delta i_{oq_i} \), which is a small-signal output current, can be expressed by Appendix E.1. The bus voltage on the common reference frame is the input signal to the ith inverter model. Therefore, by using reverse transformation, the bus voltage can be converted into an ith individual inverter reference frame.

\[
[\Delta u_{odi}] = [T_{r}^{-1}][\Delta u_{DQ}] + [T_{r}^{-1}][\Delta d], \quad \text{where}, \quad T_{r}^{-1} = \begin{bmatrix} -u_{DQ}\sin(\delta) + u_{DQ}\cos(\delta) \\ -u_{DQ}\cos(\delta) - u_{DQ}\sin(\delta) \end{bmatrix}
\]

By combining the aforementioned state-space models for three controllers of an ith inverter, which are power controller, voltage controller and current controller, and output grid side LCL filter, the complete small-signal model can be obtained.

\[
[\Delta x_{invi}] = A_{invi}\Delta x_{invi} + B_{invi}[\Delta u_{DQ}] + B_{IC}\Delta\omega_{com}\Delta x_{invi}
\]

\[
\begin{bmatrix} \Delta\omega_i \\ \Delta\epsilon_{DQ} \end{bmatrix} = \begin{bmatrix} C_{invi} & 0 \\ 0 & C_{invi} \end{bmatrix}\Delta x_{invi}
\]
where

\[
[\Delta x_{\text{inv}}] = [\Delta \delta_1 \Delta P_1 \Delta Q_1 \Delta \varphi_1 \Delta \varphi_2 \Delta \gamma_1 \Delta \gamma_2 \Delta i_{\text{di}} \Delta i_{\text{qi}} \Delta v_{\text{odi}} \Delta v_{\text{odi}} \Delta i_{\text{odi}} \Delta i_{\text{odi}}]^T
\]

The matrices \( A_{\text{inv}}, B_{\text{inv}}, C_{\text{inv}}, \) and \( C_{\text{inv}} \) are the system matrices described by Appendix C.

### 3.4. Combined Model of \( N \) Inverters

In MG, the \( N \) number of DG inverters may be operating as a source at variable distances among each other. In this section, our approach is to discuss the possible sub-model form of all individual \( i\text{th} \) to \( k\text{th} \) DG inverters and combine them with the existing corresponding network. The combined small-signal model of the “\( N \)” number of DG inverters is expressed by:

\[
[\Delta x_{\text{inv}}] = A_{\text{inv}}[\Delta x_{\text{inv}}] + B_{\text{inv}}[\Delta v_{\text{bDQ}}]
\]

\[
[\Delta i_{\text{bDQ}}] = C_{\text{inv}}[\Delta x_{\text{inv}}]
\]

where the system matrices are given by Appendix F.

### 3.5. Network and Load Model

If an \( i\text{th} \) feeder line is connected between node \( j \) and \( k \), mathematical modeling can be presented as follows.

\[
\frac{\text{d}i_{\text{line}i}}{\text{d}t} = \frac{-R_{\text{line}i} i_{\text{line}i} + \omega i_{\text{line}Q_i} + \frac{1}{L_{\text{line}i}} v_{\text{bDQ}i} - \frac{1}{L_{\text{line}i}} v_{\text{bDQ}k}}{L_{\text{line}i}}
\]

\[
\frac{\text{d}i_{\text{line}Q_i}}{\text{d}t} = \frac{-R_{\text{line}i} i_{\text{line}Q_i} - \omega i_{\text{line}D_i} + \frac{1}{L_{\text{line}i}} v_{\text{bDQ}j} - \frac{1}{L_{\text{line}i}} v_{\text{bDQ}k}}{L_{\text{line}i}}
\]

\[
[\Delta i_{\text{lineDQ}}] = A_{\text{LINE}}[\Delta i_{\text{lineDQ}}] + B_{1\text{LINE}}[\Delta i_{\text{bDQ}}] + B_{2\text{LINE}}[\Delta \omega]
\]

where

\[
[\Delta i_{\text{lineDQ}}] = [\Delta i_{\text{lineDQ}1} \Delta i_{\text{lineDQ}2} \ldots \Delta i_{\text{lineDQ}n}]^T, [\Delta i_{\text{bDQ}}] = [\Delta i_{\text{bDQ}1} \Delta i_{\text{bDQ}2} \ldots \Delta i_{\text{bDQ}m}]^T, \Delta \omega = \Delta \omega_{\text{com}}
\]

The matrices \( A_{\text{LINE}}, B_{1\text{LINE}}, B_{2\text{LINE}}, A_{\text{LINE}i}, B_{2\text{LINE}i}, \) and \( B_{1\text{LINE}i} \) are the system matrices given in Appendix F.1. If there are \( p \) load points available in a particular network, then the small-signal model can be presented as:

\[
[\Delta i_{\text{loadDQ}}] = A_{\text{LOAD}}[\Delta i_{\text{loadDQ}}] + B_{1\text{LOAD}}[\Delta i_{\text{bDQ}}] + B_{2\text{LOAD}}[\Delta \omega]
\]

\[
[\Delta i_{\text{loadDQ}}] = [\Delta i_{\text{loadDQ}1} \Delta i_{\text{loadDQ}2} \ldots \Delta i_{\text{loadDQ}p}]^T
\]

where \( A_{\text{LOAD}}, B_{1\text{LOAD}}, B_{2\text{LOAD}}, A_{\text{LOAD}i}, \) and \( B_{1\text{LOAD}i} \) are the system matrices described in Appendix G.

### 3.6. Complete Microgrid Model

It can have observed that the node voltages are used as inputs to every subsystem. In the assurance of well-defined node voltage, a virtual resistor \( r_N \) is supposed among all \( m \) nodes and grounds, which symbolic form can be defined as

\[
[\Delta v_{\text{bDQ}}] = R_N(M_{\text{INV}}[\Delta i_{\text{bDQ}}] + M_{\text{load}}[\Delta i_{\text{loadDQ}}] + M_{\text{NET}}[\Delta i_{\text{lineDQ}}])
\]

The diagonal elements of matrix \( R_N \) is equal to \( r_N \), which has a size of \( 2m \times 2m \) matrix. The mapping matrix \( M_{\text{INV}} \) and \( M_{\text{load}} \) are the size of \( 2m \times 2m \) and \( 2m \times 2p \), respectively. M
NET matrix maps the connecting transmission lines onto the network nodes having a size of $2m \times 2n$. Finally, the complete MG small-signal model is given by Equation (30).

$$
\begin{bmatrix}
\Delta x_{\text{inv}} \\
\Delta i_{\text{lineDQ}} \\
\Delta i_{\text{loadDQ}}
\end{bmatrix}
= A_{\text{MG}}
\begin{bmatrix}
\Delta x_{\text{inv}} \\
\Delta i_{\text{lineDQ}} \\
\Delta i_{\text{loadDQ}}
\end{bmatrix}
$$

(30)

where $A_{\text{MG}}$ is the state matrix and given as

$$
A_{\text{MG}} = \begin{bmatrix}
A_{\text{inv}} + B_{\text{inv}}R_{\text{NET}}M_{\text{inv}}C_{\text{inv}} + B_{\text{LINE}}M_{\text{NET}} + B_{\text{LOAD}}M_{\text{NET}} & B_{\text{inv}}R_{\text{NET}}M_{\text{NET}} + B_{\text{LINE}}R_{\text{NET}}M_{\text{load}} + B_{\text{LOAD}}R_{\text{NET}}M_{\text{load}} \\
B_{\text{LINE}}M_{\text{NET}} + B_{\text{LOAD}}M_{\text{NET}} & A_{\text{LINE}} + B_{\text{LINE}}R_{\text{NET}}M_{\text{NET}} + B_{\text{LOAD}}R_{\text{NET}}M_{\text{load}} + B_{\text{LOAD}}R_{\text{NET}}M_{\text{load}}
\end{bmatrix}
$$

(31)

4. Results and Discussion

In this section, the stability analysis, simulation, and experimental results for power sharing, voltage, and frequency regulation, are discussed. The simulations on MATLAB/Simulink are conducted on circuit configuration given in Figure 1 for three-phase 50 Hz islanded MG wherein the two paralleled connected DG1 and DG2 are connected to the RL load via feeder impedance $X_1$–$R_1$ and $X_2$–$R_2$. Moreover, the photo of the lab-scaled experiment hardware is illustrated in Figure 3. System and controller parameters that have been used in conventional and proposed control schemes are shown in Tables 1 and 2.

Figure 3. (a) General procedure of LabVIEW control system. (b) Laboratory experimental prototype.

4.1. Modeling Results

The complete model of the test system under the proposed control scheme is achieved and used to analyze the stability of the system under varying communication latencies and control gains. MATLAB/Simulink and linear analysis tools have been used to obtain modeling results by analyzing this complex system through perturbing dynamical equations. Figure 4a,b shows the stability plot for the proposed control framework by varying real power droop gain $m_P$ to trace the network trajectory. The control values of the droop gain $m_P$ where system poles appear to be in the vicinity of the unit origin are maximum.
allowable limits. Therefore, using the poles zero evolutions, the control gain sensitivity and system stability are predicted. The maximum and minimum \( m_{P} \) gain values used for the proposed control scheme are \( 1 \times 9.5^{-9} \) and \( 1 \times 9.5^{-5} \), respectively.

Figure 4c demonstrates the pole and zero traces resulting from the behavior of the MG system by varying the time delays with the proposed control scheme. Movement of system poles is captured by starting with time delay \( t_d = 0 \) and increasing it step by step to a maximum time delay of \( t_d = 3 \) s. Poles are observed in the stable region for the time delay values \( 0 > t_d < 1 \) s and outside the unit circle for the \( t_d > 1 \) s, which makes the MG system divergent and unstable.

Figure 4. Poles zero plots: (a) effect of the \( m_{P} \) variation; (b) effect of the \( n_{Q} \) variation; (c) effect of the time delay \( t_d \) on system stability.

4.2. Simulation Results

In this section, the MATLAB/Simulink-based results obtained with conventional and proposed control strategies are discussed. The simulation verifications are composed of two cases. Case 1 outlines the results obtained with a conventional control scheme, while case 2 validates the effectiveness of the proposed control strategy. The initial conditions and control parameters as shown by Tables 1 and 2 are the same for both cases.

4.2.1. Case 1: MATLAB/Simulink Results with Conventional Control Strategy

Figure 5 shows the results obtained with a conventional control scheme. The objective of this scheme is to hold the load voltage at its original state, i.e., \( V_{\text{ref}} = 300 \) V, in the presence of load disturbance. To examine the methodology, the disturbance load (\( L_{d1} = 10 \) mH, \( R_{d1} = 20 \) Ω) is exerted at time \( t_1 \), and later the conventional control scheme is activated at the time \( t_2 \). Figure 5a illustrates the load voltage deviation of 2 V even the load disturbance is
not yet exerted. This load voltage further deviates and is set at 393.5 V once the disturbance load is added at time $t_1$, as shown by Figure 5b. The load voltage drop of 4.5 V is removed once the conventional control strategy is activated at $t_2$. Although the conventional scheme is activated, still 2.3 V load voltage deviation is observed, as shown by Figure 5c. Real and reactive power sharing is illustrated by Figure 5d, while Figure 5e,f show the magnified results of real and reactive power, respectively.

![Figure 5. MATLAB/Simulink results with the conventional control scheme.](image)

4.2.2. Case 2: MATLAB/Simulink Results with Proposed Control Strategy

Figure 6 shows the results obtained with the proposed control scheme. As opposed to the conventional scheme, the initial load voltage is observed at the desired value, i.e., $V_{ref} = 300$ V, as shown by Figure 6a. Once the disturbance load $jX_d/R_d$ is exerted at $t_1$, an obvious 3 V load voltage drop is depicted, as illustrated by Figure 6b. The proposed control scheme is activated at $t_2$, as shown in Figure 6c, where load voltage has resorted to nearly its original state. Figure 6d,g show the real and reactive power-sharing results, respectively, while Figure 7 demonstrates the frequency restoration result using the proposed methodology.
Figure 6. MATLAB/SIMULINK results with proposed control scheme. (a) Behavior of load voltage and inverter terminal voltages. (b) Disturbance load $jX_1/R_1$ added at $t_1$. (c) Voltage regulation with proposed control scheme. (d) Real power sharing. (e,f) Magnified active power. (g) Reactive power sharing. (h) Magnified reactive power.
4.3. Experimental Results

An accompanying experiment is carried out to investigate the proposed control scheme. The experiment is conducted for a three-phase, 50-Hz scaled islanded MG prototype, as depicted in Figure 3. The system consists of two identical paralleled DG units with a maximum rating of 3 A, 30 V, connected with RL load via feeder 1 and feeder 2. Ethernet module USR TCP 232 is used for serial communication transmission of data among the data terminal equipment (DTE) and data communication equipment (DCE). The whole platform of islanded MGs is controlled by the desktop control system, wherein LabVIEW has been used to control the DG units.

Figure 8a shows the behavior of load voltage in the presence of disturbance load under a conventional control scheme. Load disturbance of value \( L_{d1} = 1 \text{ mH}, R_{d1} = 5 \Omega \) is added at \( t_1 \) as shown in Figure 8b (magnified). From the same figure, 1 V load voltage deviation is observed once the disturbance load is added. This deviation is removed when the conventional control strategy is activated at \( t_2 \). However, under the conventional control scheme, still, 2.5 V load voltage deviation is observed, as compared to its original state \( (V_{ref} = 30 \text{ V}) \) as shown in Figure 8c. Figure 8d shows the DGs and load voltage response in the presence of the disturbance load \( jX_{d1}/R_{d1} \) under the proposed control scheme. About 0.5 V load voltage deviation is noticed once the disturbance load is exerted at \( t_1 \), as shown in Figure 8e (magnified result). This load voltage deviation is removed, and load voltage is restored to its original state \( (V_{ref} = 30 \text{ V}) \), as shown in Figure 8f (magnified result). System frequency error measured at inverter terminal is regulated within an acceptable range once the proposed control scheme is activated at \( t_2 \), as in Figure 8g.
Figure 8. Experimental results. (a) Behavior of load voltage and inverter terminal voltages with conventional control scheme. (b) Disturbance load $jX_{dl}/R_{dl}$ added at $t_1$. (c) Voltage regulation with conventional control scheme. (d) Behavior of load and inverter terminal voltages with proposed control scheme. (e) Disturbance load $jX_{dl}/R_{dl}$ added at $t_1$. (f) Voltage regulation with proposed control scheme. (g) Frequency regulation. (h) Magnified Frequency Regulation Curve.
5. Conclusions

In this paper, an enhanced droop control scheme is presented for microgrids working in islanded mode. The control scheme is able to restore the load voltage deviations and fluctuations due to the droop effect and load effect. The proposed study consists of two decoupled methods, the $Q-V$ control layer shares the reactive power proportionally and restores the load voltage magnitudes, while the $P-f$ control layer addresses the active power sharing and frequency stability. Both sets of control layers have been implemented in a distributed manner. At the same time, the distributed secondary layer is used to regulate the system frequency. Mathematical small-signal models were employed to analyze the performance of the presented scheme using pole-zero evolutions with regard to system stability toward variations in control parameters. Various simulations and experimental results, in comparison to the conventional scheme, showed that the proposed methodology is very effective.

**Author Contributions:** M.Z.K., C.M. and S.H. contributed to the conceptualization behind this work. M.Z.K. has prepared the write-up and manuscript. S.H., W.A. and E.M.A. helped with small-signal modeling and with the write-up, sectionalizing, and appropriate referencing. All authors have read and agreed to the published version of the manuscript.

**Funding:** The authors extend their appreciation to the Deputyship for Research and Innovation, Ministry of Education in Saudi Arabia, for funding this work through the project number “375213500”. The authors also would like to extend their sincere appreciation to the central laboratory at Jouf University for supporting this study.

**Institutional Review Board Statement:** Not applicable.

**Informed Consent Statement:** Not applicable.

**Acknowledgments:** The authors would like to thank the editor in chief, the associate editors, and the reviewers for their worthy suggestions, time, and effort in improving and finalizing this paper. The authors would further like to thank Asad Khan (asadkhan@sjtu.edu.cn) for providing the support in software and validation.

**Conflicts of Interest:** The authors declare no conflict of interest.

**Appendix A**

The current injection into $i$th bus written as

$$I_i = \sum_{j=1}^{N} Y_{ij} V_j$$

where $Y_{ij}$ terms are admittance matrix elements. By substituting Equation (1) into (2), yields:

$$S_i = V_i \left( \sum_{j=1}^{N} Y_{ij} V_j \right)^* = V_i \sum_{j=1}^{N} Y_{ij}^* V_j^*$$

where $V_i$ is a phasor term, have the magnitude and angle that can be expressed as $V_i = |V_i| \angle \phi_i$, $Y_{ij}$ is the complex-valued admittance matrix element that can be defined $G_{ij}$ and $B_{ij}$ as the real and imaginary parts, i.e., $Y_i = G_{ij} + jB_{ij}$; therefore the Equation (A2) can be expressed as

$$S_i = V_i \sum_{j=1}^{N} Y_{ij}^* V_j^* = |V_i| \angle \phi_i \sum_{j=1}^{N} (G_{ij} + jB_{ij})^* |V_j| \angle \phi_j = |V_i| \angle \phi_i \sum_{j=1}^{N} (G_{ij} - jB_{ij}) (|V_j| \angle \phi_j)$$

$$= \sum_{j=1}^{N} |V_i| \angle \phi_i (|V_j| \angle \phi_j) (G_{ij} - jB_{ij}) = \sum_{j=1}^{N} |V_i| |V_j| \angle (\phi_i - \phi_j) (G_{ij} - jB_{ij})$$

(A3)
By converting the phasor expression into complex function of sinusoids, i.e., \( V = |V| \angle \varphi = |V| (\cos \varphi + j \sin \varphi) \),

\[
S_i = \sum_{j=1}^{N} |V_i| |V_j| \angle (\varphi_i - \varphi_j) (G_{ij} - jB_{ij}) 
\]

\[
= \sum_{j=1}^{N} |V_i||V_j| \angle (\cos(\varphi_i - \varphi_j) + j \sin(\varphi_i - \varphi_j)) (G_{ij} - jB_{ij}) 
\]

\[
= P_i + jQ_i 
\]  

Appendix B

\[
\varphi_{ij} = \frac{X_P}{V_{ij}} \quad V_i - V_j = \frac{X_Q}{V_i} 
\]

Appendix C. System Matrices

\[
A_{inv} = \begin{bmatrix} 
A_{Pi} & 0 & 0 & B_{Pi} \\
B_{C1}C_{P1} & 0 & 0 & 0 \\
B_{GSF1}D_{C1}C_{P1} & B_{C2}C_{Pi} & 0 & 0 \\
B_{GSF2}[T_S^{-1} 0 0] + B_{GSF3}C_{P1} & B_{GSF1}D_{C1}C_{Pi} & B_{GSF1}C_{Pi} & A_{GSF1} + B_{GSF1}(D_{C1}D_{C2} + D_{C2}) \\
\end{bmatrix}_{13 \times 13} 
\]

\[
B_{inv} = \begin{bmatrix} 
0 \\
0 \\
B_{GSF2}T^{-1} \\
\end{bmatrix}_{13 \times 2} 
\]

\[
B_{invcom} = \begin{bmatrix} 
B_{Pwcom} \\
0 \\
0 \\
\end{bmatrix}_{13 \times 1} 
\]

\[
C_{inv} = \begin{bmatrix} 
[T_C 0 0 0] \\
0 0 0 0 \\
\end{bmatrix}_{13 \times 2} 
\]

where \( A_{MG} \) is the state matrix and given as

\[
A_{MG} = \begin{bmatrix} 
A_{inv} + B_{inv}R_{N}M_{inv}C_{sec} & A_{line} + B_{line}R_{N}M_{NET} & B_{inv}R_{N}M_{load} \\
B_{LOAD}R_{N}M_{line}C_{new} + B_{LOAD}C_{new} & B_{LOAD}R_{N}M_{NET} & B_{LOAD}R_{N}M_{load} + B_{LOAD}R_{N}M_{load} \\
B_{LOAD}R_{N}M_{line}C_{new} + B_{LOAD}C_{new} & B_{LOAD}R_{N}M_{NET} & A_{load} + B_{LOAD}R_{N}M_{load} \\
\end{bmatrix} 
\]

Appendix D. Inner Zero Control: Voltage and Current Controller Matrices

Small-signal state-space equations for voltage loop and current loop are

\[
\begin{bmatrix} 
\Delta v_{dq}^* \\
\Delta i_{dq}^* \\
\end{bmatrix} = C_c \begin{bmatrix} 
\Delta \varphi_{dq} \\
\Delta \gamma_{dq} \\
\end{bmatrix} + D_c1 \begin{bmatrix} 
\Delta v_{odq} \\
\Delta i_{odq} \\
\end{bmatrix} + D_c2 \begin{bmatrix} 
\Delta i_{dq} \\
\Delta v_{odq} \\
\end{bmatrix} 
\]

\[
\begin{bmatrix} 
\Delta v_{dq}^* \\
\Delta i_{dq}^* \\
\end{bmatrix} = C_c \begin{bmatrix} 
\Delta \gamma_{dq} \\
\Delta \gamma_{dq} \\
\end{bmatrix} + D_c1 \begin{bmatrix} 
\Delta i_{dq} \\
\Delta v_{odq} \\
\end{bmatrix} + D_c2 \begin{bmatrix} 
\Delta i_{dq} \\
\Delta i_{odq} \\
\end{bmatrix} 
\]

where

\[
C_c = \begin{bmatrix} 
K_{PCI} & 0 \\
0 & K_{PCI} \\
\end{bmatrix}, D_c1 = \begin{bmatrix} 
K_{PCI} & 0 \\
0 & K_{PCI} \\
\end{bmatrix}, D_c2 = \begin{bmatrix} 
-K_{PC} & -\omega L_{fi} & 0 & 0 & 0 \\
\omega L_{fi} & -K_{PC} & 0 & 0 & 0 \\
\end{bmatrix} 
\]
Here, both $\Delta_{W_{\text{DI}}}^i$ and $\Delta_{W_{\text{DI}}}^j$ are perturbations for PI controllers in the auxiliary state. $K_{P\text{CI}}$ and $K_{I\text{CI}}$ are the proportional and integral gains for the voltage controller loop, respectively, while $i_{\text{Di}}$ and $i_{\text{Di}}$ are system measurements.

Appendix E. Grid Side Filter Model

LC filter and coupling inductance, their linearization small-signal equations are represented in following equations, where $w_{\text{o}}$ at a given operating point, is the steady-state frequency.

$$
\begin{bmatrix}
\Delta i_{\text{ldqi}} \\
\Delta v_{\text{ldqi}} \\
\Delta i_{\text{odqi}}
\end{bmatrix} = A_{\text{GSF}} \begin{bmatrix}
\Delta i_{\text{ldqi}} \\
\Delta v_{\text{ldqi}} \\
\Delta i_{\text{odqi}}
\end{bmatrix} + B_{\text{GSF}} \begin{bmatrix}
\Delta v_{\text{ldqi}} \\
\Delta v_{\text{ldqi}} \\
\Delta i_{\text{odqi}}
\end{bmatrix} + B_{\text{GSF}} \begin{bmatrix}
\Delta \omega
\end{bmatrix}
$$

Appendix E.1. Complete Model of an ith Inverter

$$
[\Delta i_{\text{DQ}}] = [T_{\gamma}] [\Delta i_{\text{od}}] + [T_{\xi}] [\Delta \delta] = \begin{bmatrix}
\cos(\delta) & -\sin(\delta) \\
\sin(\delta) & \cos(\delta)
\end{bmatrix} [\Delta i_{\text{odq}}] + \begin{bmatrix}
-I_{\text{od}} \cos(\delta) & -I_{\text{od}} \sin(\delta) \\
I_{\text{od}} \sin(\delta) & I_{\text{od}} \cos(\delta)
\end{bmatrix} [\Delta \delta]
$$

where the transformation matrix $T_{\gamma}$ is,

$$
T_{\gamma} = \begin{bmatrix}
\cos(\delta) & -\sin(\delta) \\
\sin(\delta) & \cos(\delta)
\end{bmatrix} [\Delta i_{\text{odq}}] ; T_{\xi} = \begin{bmatrix}
-I_{\text{od}} \cos(\delta) & -I_{\text{od}} \sin(\delta) \\
I_{\text{od}} \sin(\delta) & I_{\text{od}} \cos(\delta)
\end{bmatrix} [\Delta \delta]
$$

Appendix F. Combined Model of N Inverters

$$
[\Delta x_{\text{inv}}] = A_{\text{inv}} \cdot [\Delta x_{\text{inv}} 1 \Delta x_{\text{inv}} 2 \ldots \Delta x_{\text{inv}} N]^T
$$

$$
A_{\text{inv}} = \begin{bmatrix}
A_{\text{inv} 1} + B_{1\text{wcom}} C_{\text{inv} 1} & 0 \\
0 & A_{\text{inv} 2} + B_{2\text{wcom}} C_{\text{inv} 2}
\end{bmatrix}_{13N \times 13N} \quad B_{\text{inv}} = \begin{bmatrix}
B_{\text{inv} 1} \\
B_{\text{inv} 2}
\end{bmatrix}_{13N \times 2m}
$$

$$
[\Delta v_{\text{DQ}}] = [\Delta v_{\text{DQ}} 1 \Delta v_{\text{DQ}} 2 \ldots \Delta v_{\text{DQ}} N] ; C_{\text{inv}} = \begin{bmatrix}
C_{\text{inv} 1} & 0 \\
0 & C_{\text{inv} 2}
\end{bmatrix}_{2N \times 13N}
$$

Appendix F.1. Network and Load Model

$$
A_{\text{LINE}} = \begin{bmatrix}
A_{\text{LINE} 1} & 0 \\
0 & A_{\text{LINE} 2}
\end{bmatrix}_{2N \times 2n} \quad B_{\text{LINE}} = \begin{bmatrix}
B_{\text{LINE} 1} \\
B_{\text{LINE} 2}
\end{bmatrix}_{2n \times 2m} \quad B_{\text{LINE} i} = \begin{bmatrix}
B_{\text{LINE} i 1} \\
B_{\text{LINE} i 2}
\end{bmatrix}_{2n \times 2m}
$$

$$
A_{\text{LINE} i} = \begin{bmatrix}
R_{\text{line} i} & \omega_{i} \\
-\omega_{i} & -R_{\text{line} i}
\end{bmatrix} \quad B_{\text{LINE} i} = \begin{bmatrix}
I_{\text{line} Q} \\
-I_{\text{line} D}
\end{bmatrix} \quad B_{\text{LINE} i} = \begin{bmatrix}
0 & -1 \\
0 & 0
\end{bmatrix}_{2 \times 2m}
$$

The state equations for RL load connected via an ith node can be written as follows

$$
\frac{di_{\text{loadDi}}}{dt} = -R_{\text{loadDi}} i_{\text{loadDi}} + \omega_{\text{loadDi}} i_{\text{loadDi}} + \frac{1}{L_{\text{loadDi}}} v_{\text{Di}}
$$

$$
\frac{di_{\text{loadQi}}}{dt} = -R_{\text{loadQi}} i_{\text{loadQi}} - \omega_{\text{loadDi}} i_{\text{loadDi}} + \frac{1}{L_{\text{loadQi}}} v_{\text{Qi}}
$$
Appendix G. Network and Load Model

\[
A_{LOAD} = \begin{bmatrix}
A_{LOAD1} & 0 \\
0 & A_{LOAD2}
\end{bmatrix}_{2p \times 2p}, \quad B_{1LOAD} = \begin{bmatrix}
B_{1LOAD1} \\
B_{1LOAD2}
\end{bmatrix}_{2p \times 2m}, \quad B_{2LOAD} = \begin{bmatrix}
B_{2LOAD1} \\
B_{2LOAD2}
\end{bmatrix}_{2m \times 2m}
\]

where

\[
A_{LOAD1} = \begin{bmatrix}
-\frac{R_{load}}{\omega_1} & \frac{\omega_1}{L_{load}} \\
-\omega_1 & -\frac{R_{load}}{\omega_1}
\end{bmatrix}, \quad B_{2LOAD} = \begin{bmatrix}
I_{loadQi} \\
-\frac{1}{L_{load}} I_{loadQi}
\end{bmatrix}, \quad B_{1LOAD} = \begin{bmatrix}
0 \\
\frac{1}{L_{load}}
\end{bmatrix}_{2 \times 2m}
\]
